The present schedule provides for an 8-cent fare where exact change is provided, otherwise 10 cents; seven tokens are sold for 50 cents, and a book of sixteen tickets for $1. Express bus service at a fare of 10 cents is provided.

Akron newspapers were warm in their praise of the position taken by the company. "The public will approve the agreement between Council and the N. O. P. & L. Co.," declared the *Times-Press*. "As an experiment the current franchise has had but small opportunity."

The *Beacon Journal* said that "Manager Blinn and his company will make friends in Akron by their own fairness in the negotiations which led to the result." Continuing its editorial, the *Beacon Journal* declared that "the company had shown good sportmanship in making up its mind to go along without asking an increase in fare under present conditions."

The franchise under which the company is now operating became effective on May 26, 1929, and expires on Sept. 1, 1930. The idea was that a short-term contract at rates higher than those formerly in effect would furnish reliable data for a reasonably long term franchise.

Vaughan Tie Tamper Patent Upheld

Judge Hugh Morris of the United States District Court of Delaware in an opinion handed down on April 23, decided the suit of Fanny Minton Vaughan and the Ingersoll-Rand Company against the Gardner-Denver Company for infringement of the Vaughan tie tamper patent No. 1147660 in favor of the plaintiffs. The Ingersoll-Rand Company is the principal licensee under the patent.

Reorganization of Utah Line May Be Speeded

Reorganization of the Salt Lake & Utah Railroad and release from its present receivership may be possible at an earlier date than was expected, through action of the United States Supreme Court in denying the suit of the United States for precedence in claims against railroads which borrowed federal funds during and after the world war. D. P. Abercrombie, receiver for the railroad said that "assuming the government recognizes the Supreme Court decision as a precedent in the Salt Lake & Utah case, the situation should permit a reorganization at an early date."

The Supreme Court decision was made in the case of the United States vs. the Guarantee Trust Company, New York, acting as trustee of the bond issue of the Minneapolis & St. Louis Railroad. The government sought to enforce prior payment of a loan, similar to the $830,000 borrowed by the Salt Lake & Utah from a revolving fund established during the war for the benefit of the small railroads. The court held that the government, in making loans under this section, was engaged in business, and therefore entitled to no priority.

Supreme Court Upholds Lower Court's Decatur Decree

In the case of the Georgia Power Company, Atlanta, Ga., versus the city of Decatur a judgment of the Supreme Court of Georgia affirming a decree enjoining a street railway from violating an ordinance and a contract requiring it to carry passengers for a certain fare (in this case 5 cents) was affirmed by the United States Supreme Court on May 19. The railway contended that the rate was confiscatory and that the franchise and the rate contract had expired.

The State Supreme Court had held that the contract specifying the rate was still in effect, and the United States Supreme Court accepted the state court's construction of the statutes of the state and the ordinance and rate contract, and held that, inasmuch as the contract was still in effect, the street railway was not entitled to relief therefrom, although the company was losing money.

Competition Brings Protest at Duluth

An injunction is sought by the Duluth Street Railway, Duluth, Minn., to restrain the Gopher-Badger Bus Company from operating between 6 a.m. and 10 p.m. on Duluth streets having double street car tracks, except on condition that the buses do not stop to pick up or discharge passengers on West Third Street between Vernon and 38th Avenue West. The railway charges that the bus company has carried local passengers between the two points. It cites an ordinance passed by the City Council on June 16, 1924, giving the railway rights and privileges on all such streets.

The bus company points out that there have always been double tracks on the main thoroughfares leading from Superior to Duluth and that the Superior White Company, prior to its purchase in April, 1925, by the railway, operated despite the ordinance with no objection on the part of the electric railway. The answer also charges that the railway, which owns and operates the Duluth-Superior Coach Company, has had a monopoly on Twin-Ports transportation for many years and that the present action is intended to maintain and continue such monopoly.

Madison Company Demurs to Paving

The Madison Railways, Madison, Wis., has declared that it will incur no further liability for paving of track zones until it has paid its present obligation to the city. This is the reply to the city by the company in answer to the city's request that it prepare for permanent improvement of its right-of-way on Winnebago Street from the Yahara River to Second Street.

In a letter to city officials, the company says that it is not able to make the improvement at this time and suggests that the work be deferred until later. The city awarded the paving contract on Winnebago Street a year ago, but work was delayed until this year because the railway was not prepared to carry out its share of the improvement at that time. At the next Council meeting, city officials will decide whether to postpone work for another year, or proceed and charge the cost against the utility.

The Madison Railways has applied to the Railroad Commission for an increase in fares. Hearings on the application will begin June 9.

Columbia Case Decided

(*Continued from page* 312)

The company filed a petition for authority to discontinue service and for a hearing on the matter and the Railroad Commission, by a vote of four to three, allowed the company to discontinue service—or rather to let the service stay stopped.

Meanwhile the state attorney general asked for a rehearing. One member of the commission had died and another had been appointed in his place, and when it came to a vote on the motion to reverse its former ruling, the commission decided four to three so to do and the company was ordered to resume service. The attorney general petitioned to the State Supreme Court for a mandamus to compel the company to restore service. Various other steps were taken and finally the matter went to the United States Supreme Court.

Transportation has been an important issue in municipal politics. In the recent election of a Mayor and City Councilmen it came in for much discussion, even though at the time the issue was in the United States Supreme Court.

A bus company has been supplying more or less indifferent service since the street cars ceased to run, but due to the fact that the matter was in the courts, the company hesitated in making any heavy investment in equipment. Jitneys flourished for a time, but finally the City Council ruled them off the streets so that the bus company might get all the patronage.

Now citizens hope to see trolleys again on the streets. The tracks and the overhead are in place, but in need of repair. The carhouse is intact.

Taxi Cuts Seattle Revenue

Demand for action in the taxicab situation in Seattle, Wash., has been made on the City Council by Moritz Thomsen, who urged that Sam W. Taggart be permitted to control all taxicabs in the city for 25 years, in return for guaranteeing the city at least $500,000. With taxicab competition increasing, the $20,000 monthly loss now sustained by the municipal railway will be increased unless the city takes steps to control the taxicabs, Mr. Thomsen declared. Councilmen contend, however, that loss of revenue by the municipal railway results chiefly from reduction in service on the bus and car lines, and from increased use of private automobiles, rather than from competition by taxicabs. One councilman declares that "by reducing service, the railway is playing into the hands of the taxicab companies." Long waits for street cars and slow service are said to explain the falling off in railway revenue.

Move to Restrict Freight Service of Interurban

Whether the transition of a transportation activity induced by changing conditions produces rights which supercede the regulations imposed in a municipal franchise is a question which is expected to go before the Ohio courts. The question arises from a dispute between the Cincinnati & Lake Erie Railroad and Springfield property owners over the operation of freight trains on company lines. On April 14 developments pointed to an early attempt on the part of the property owners to obtain an injunction against the company, with the latter prepared to contest the suit to the limit.

Some weeks ago the property owners on streets traversed by the company's lines asked the City Commission to enforce the terms of the franchise ordinance, which limits freight operation. When the franchise was granted a score of years ago, the passenger business furnished the bulk of the income and with little freight business except light express and milk. Today, through freight service in regular freight cars has become a common practice.

Springfield is the hub of the Cincinnati & Lake Erie lines. Hence the reason for the company's extra interest in the local situation. Following receipt of the petition from property owners, the commission instructed the railroad to obey the terms of the ordinance. However, twenty large industrial concerns have protested enforcement of the ordinance, and beyond the gesture, the commission is expected to take no further steps in the matter. But property owners declare they are prepared to go into the courts to seek an injunction. Meantime, the freight service continues.

Rate War Among Springfield Taxis

Taxicab companies in Springfield, Mass., have started a rate war. The Aldermen established a minimum rate for metered cabs of 35 cents for the first third of a mile and 10 cents for each additional third of a mile. One company ignored the order and operated its cabs at 20 cents for the first quarter mile and 5 cents for each additional quarter to test the legality of the municipal ruling. The city solicitor advised against taking away the license of the offending company, being doubtful as to the city's powers. Other companies then began carrying passengers anywhere in the city for 50 cents. As the latest step the Aldermen have adopted a new minimum rate for metered cabs of 25 cents for the first quarter mile and 5 cents for each additional quarter mile. The zone rates for unmetered cabs have been reduced to a 50-cent fare for one or two passengers and 25 cents for each additional passenger in the first zone, with 25-cent advances in the second and third zones, respectively.

City After Local Detroit Buses

Detroit's City Council has refused to approve the contract made by the Street Railway Commission for the purchase of fifty 40-passenger buses. Action has been postponed for at least 30 days. The Council voted to defer the purchase pending the outcome of negotiations between the Department of Street Railways and the Detroit Motor Bus Company for taking over the company's lines for articulation with the city system.

Council members desire to know where buses would be used, and the commission was asked by the Council for a progress report on its negotiations with the bus company. When the bus purchase was first authorized by the commission, Frank Couzens, then a commissioner, asked if the purchase was necessary in view of the probable taking of equipment from the private company. President Barlum, of the commission, said the new equipment would be needed whether or not the bus company equipment was taken over by the city.

Northern Ohio Withdraws from Operating Canton City Lines

After months of negotiations an agreement has finally been reached in the Canton, Ohio, transportation situation. Two companies, one the Canton Traction Company and the other the Canton Motor Coach Company, are to supply the city with transportation. The Canton Traction Company takes over part of the lines formerly operated by the Northern Ohio Power & Light Company. The agreement provides for an exchange of free transfer between the two companies. The fare is to be 7 cents cash, eight tickets for 50 cents, with a 5-cent school ticket.

The Oxford Avenue, the Mahoning Road, and the Bryan Avenue lines operated by Northern Ohio Power & Light Company are abandoned under the arrangement. Two tracks are to be taken off the Public Square and the loop known as the Cleveland Avenue-Fifth Street-Tuscarawas loop used by Stark Electric Company's interurban cars is abandoned. The Stark Electric cars will turn from Cleveland into Tuscarawas and then back to the Square.

In lieu of the Northern Ohio Power & Light Company being required to remove its abandoned tracks, the city is to receive a lump sum of $100,000. Bus service by the Canton Motor Coach Company is to supplant the abandoned lines and the Coach Company is to cease operating buses parallel to the East Tuscarawas line, which is to be operated by the Canton Traction Company. Other lines to be operated by the Traction Company are the Navarre-Garfield Avenue, Lake line, and the West Tuscarawas line. Suburban service from the Public Square of Canton to the Public Square of Massillon is to continue. Whether this suburban line will be taken over by the Canton Traction Company is a matter yet to be determined.

The Canton Traction Company is made up largely by Canton men and is not a subsidiary of the Northern Ohio Power & Light Company, being en- Ohio Power therefore withdraws from the Canton city transportation field.

PERSONAL MENTION

New Cleveland Men in Office

Brief Accounts of the Careers of the Representatives of the Van Sweringens Recently Elected to Executive Posts With the Cleveland Railway

ON APRIL 24 Paul Wilson, vice-president and treasurer of the Cleveland Railway, Ralph W. Emerson, vice-president and general manager, and Charles H. Stanley resigned as directors of the railway. In their places the following were elected: Charles L. Bradley, who was also made chairman of the board, Alva Bradley and Otto Miller. In addition, George D. McGwinn was made vice-president of the company. These changes were brought about by the desire of Messrs. O. P. and M. J. Van Sweringen, who control the Cleveland Railway through Metropolitan Utilities, Inc., to have active representation on the board and in the executive operating staff of the company.

Charles L. Bradley is rated as the closest business associate of O. P. and M. J. Van Sweringen. He has been closely identified with Van Sweringen enterprises since July 24, 1927, when he became president of the Cleveland Union Terminals Company.

Mr. Bradley and his brother, Alva R. Bradley, are members of an old and wealthy Cleveland family. Their grandfather was Capt. Alva Bradley, who sailed the Great Lakes and made a fortune in the shipping business. Their father, M. A. Bradley, put the money to work in downtown Cleveland real estate, large parcels of which are still owned by the Bradley estate.

Both Charles and Alva Bradley were graduated from Cornell University.

Charles Bradley attracted attention during the war as head of the Cleveland liberty loan organization—during the third, fourth and fifth campaigns. In 1919 he was made vice-president of the Union Commerce National Bank. When the Union Trust merger was completed he was made vice-president and later general manager of that company.

In 1927 the Van Sweringens asked him to take over the job of completing the Cleveland union terminal and he succeeded O. P. Van Sweringen as president of the Cleveland Union Terminals Company. On April 26, 1929, he was made chairman of the board of the Erie Railroad, which is controlled by the Van Sweringens. Also, in 1928, he headed a syndicate which acquired control of the Midland Bank. This bank will move shortly to a new building in the Van Sweringen terminal area. He is also a director of a number of other companies, including the Cleveland Hotel Corporation, Cleveland Traction Terminals Company, Otis Steel Company, White Motor Company, and Hupp Motor Car Corporation.

Alva Bradley is best known at this time in Cleveland as president of the Cleveland Baseball Club. Charles Bradley is also a director of the club. Alva Bradley was a director of the Cleveland Trust Company for ten years. He resigned in 1928 to become associated with his brother as a director of the Midland Bank. He is also a director of the Chesapeake & Ohio Railroad, chairman of the board of the Cleveland Builders Supply & Brick Company, and chairman of the Cleveland & Buffalo Transit Company. In 1929 he was president of the Cleveland National Air Race & Show Corporation under whose auspices the national air races were conducted.

At top, C. L. Bradley
At left, G. D. McGwinn
At right, Alva Bradley
At bottom, Col. Otto Miller

George D. McGwinn comes into electric railway operation through the channels of building management and construction. Mr. McGwinn was a specialist in building management. Among the structures of which he was in charge were the Citizens and the Union Commerce National Bank buildings. When the Union Trust merger was brought about, Mr. McGwinn was confronted with the problem of housing the forces of four banks in a building that was considered too small for one. He managed it for three years, while the Union Trust building was under construction, and then was made vice-president and building manager of the Union Trust Company.

When Charles Bradley left the Union Trust Company to become president of the Cleveland Union Terminals Company, he took Mr. McGwinn with him as vice-president of the terminals company.

The two became known as the team of Bradley and McGwinn. As expert "trouble shooters" they proceeded to mop up one difficulty after another that confronted them in the completion of the mammoth terminal project.

Upon becoming vice-president of the Cleveland Railway, Mr. McGwinn resigned as vice-president of the terminals company, which was considered a pretty good indication that most of the difficulties in the way of the completion of the terminal were solved.

Otto Miller is a partner in Hayden & Miller & Company, which he founded in 1903 with Warren S. Hayden. As an investment banker he has participated in the sale of numerous Van Sweringen security issues and has been a director in a number of companies they control, including the Chesapeake & Ohio and Hocking Valley railroads. Mr. Miller is a veteran of the Spanish-American War. He was a member of the governor's staff for many years and a captain in Troop A, exclusive social and military cavalry organization in Cleveland. In 1928 he was elected president of the Western Reserve Historical Society.

Harry A. Osgood Master Mechanic at Binghamton

Harry A. Osgood has recently been appointed master mechanic of the Triple Cities Traction Company, Binghamton, N. Y., to succeed Frank Hampshire, who has been with the company for 23 years, the last eight years as master mechanic.

Mr. Osgood comes from the Massachusetts Northeastern Street Railway, operating in Amesbury, Haverhill, Lawrence, Newburyport and Saulsbury, Mass., and Salem, N. H.

Mr. Osgood started his railway career with the Massachusetts company in 1907 and has been master mechanic for the past ten years. His home was at Salem, N. H., where he has been active in local affairs, serving as chairman of the board of trustees of the First Congregational Church, member of the board of water commission, director in a local bank and member of the New England Street Railway Club. He is a Shriner.

Col. A. T. Perkins Honored

Members of the 327th and 359th Engineers and the Society of American Military Engineers held a special meeting on the snagboat *John Macomb* the night of April 29 to honor Col. Albert T. Perkins, vice-president of the City Utilities Company, St. Louis, who recently was placed in the auxiliary reserve of the United States Army and automatically relieved of the post of commanding officer of the 327th Engineers of the 102nd Division. Col. H. Austill, who succeeded Col. Perkins as commander, made the principal address. On behalf of the engineers he presented Col. Perkins a loving cup as a remembrance. In making his response, Col. Perkins stressed the need for national defense and an organized reserve corps.

Messrs. Vandeveer, Barkey and Lathrop in Detroit Changes

Recent changes in the personnel of the Department of Street Railways at Detroit, Mich., include the removal of Arthur L. Barkey, claims attorney for the department, and the resignation of Rufus G. Lathrop, secretary to the commission.

Mr. Lathrop has served the commission since 1925. In accepting his resignation the commission voted unanimously to write a vote of confidence in Mr. Lathrop into the records of the commission. His successor has not been named.

Mr. Barkey will return to his old position as assistant corporation counsel and the former position of claims attorney will not be filled. A new position, to be known as general trial attorney for the Department of Street Railways, has been created and to it Fred L. Vandeveer has been appointed. Mr. Vandeveer has been head of the claims department of the Travelers' Insurance Company for 27 years and his new appointment was made upon motion of Commissioner Dohany, recently appointed a committee of one to investigate the D.S.R. claims division. The new position will be under control of the D.S.R., and separate from the Corporation Counsel's office.

Glenn C. Spink, who served in Mayor Bowles' campaign headquarters during the last election, has been named employment manager of the Department of Street Railways, at Detroit, Mich.

Mr. Spink succeeds Joseph A. Burman. Wesley C. Stephens was the first man to replace Mr. Burman. Mr. Stephens was on the job 72 hours when the mayor ordered Mr. Burman, one of the veterans of the organization, to be restored.

✦

A. Le Roy Hodges, formerly manager of the Brockton division of the Eastern Massachusetts Street Railway, has been appointed manager of the Boston, Worcester & New York Street Railway, operating an extensive system of railway and bus lines, with service by bus reaching from Massachusetts towns to New York. Mr. Hodges' railway experience dates back to 1908 with the Westchester, Kennett & Wilmington Railway at Kennett Square, Pa., and covers service on other properties in the East and in the Middle West, notably in the post of assistant general manager of the Brooklyn City Railroad.

✦

R. A. Gallagher has been appointed comptroller of the Central Public Service Corporation, Chicago, Ill. He will have jurisdiction over the accounting of all properties in the Central Public Service Corporation group, which operates in 471 communities of the United States and in two provinces of Canada.

✦

John R. Marsh Advanced at Atlanta

"P. S. Arkwright, president, announces the appointment of John R. Marsh, formerly assistant manager, as manager, public relations department, Georgia Power Company, succeeding L. K. Starr, resigned."

John R. Marsh

That was all there was to the formal card issued recently to those who might be interested, about the advancement to one of the most important posts of its kind in the utility field of one of the ablest and youngest of the men engaged in this particular form of activity.

John R. Marsh has worlds of experience that qualifies him technically for the new post, but more than that he has innate and cultivated attributes of inestimable value to the incumbent of a position such as his. These have been unmistakably reflected in his work on *Two Bells,* distributed to patrons of the railway, and on the company's publication intended for distribution among the employees. Not only does he write well, but there is that divine touch about what he does which reflects the milk of human kindness that enables him to clothe a fact in garments of fancy. That, of course, is art. And John R. Marsh is an artist.

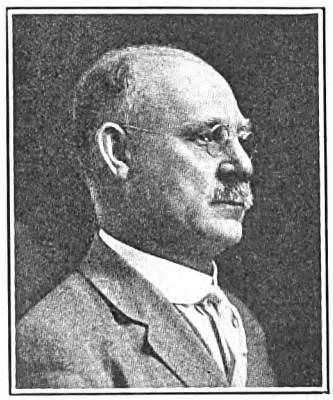
Biographically speaking, Mr. Marsh was born in Maysville, Ky., on Oct. 6, 1895. He was graduated from University of Kentucky, at Lexington, with the degree of A.B. in 1916. He worked as reporter on newspapers in Lexington, Ky., following his graduation, and served over seas during the World War. He moved to Atlanta in 1920 and worked as reporter on the *Atlanta Georgian.* That post he resigned in April, 1922, to take a position with the public relations department of the Georgia Power Company, but left the company after a few months to re-enter newspaper work, serving with the *Atlanta Journal* and with the Associated Press in Atlanta and Washington. He returned to the Georgia Power Company in September, 1924, and shortly thereafter was appointed assistant manager, public relations department, serving in this capacity until appointed manager of the public relations department on May 9, 1930.

Charles O. Birney, Car Designer, Retires After Thirty Years

Charles O. Birney has resigned from the Stone & Webster organization. After thirty years of constructive labor in the electric railway business, Mr. Birney has decided to allow himself more leisure for those pursuits which his very active life has hitherto denied to him.

It was in 1906, the year Mr. Birney was made a member of the Stone & Webster division as a car inspector, that he found real scope for his constructive powers. In 1909 he designed the continuous "T" post and continuous sash type of car, a radical departure from the standard type, so much so, indeed, that it was difficult to persuade the car builders to undertake the first order, which was for the Jacksonville Traction Company. This type has now become widely used.

When jitneys became serious competitors of electric railways in 1915, it was Mr. Birney who relieved the situation by designing the one-man safety car, which is now universally associated with his name. Like all drastic innovations, this one was received doubtfully at first, but the responsible operating executives of Stone & Webster were confident of the possibilities of the new car, and their confidence was justified. It is estimated that this method of construction and operation today is saving the electric railway industry more than $30,000,000 a year. From that time until the present, Mr. Birney has worked to improve methods of car construction and operation.



Charles O. Birney

Charles O. Birney was born about 63 years ago. He began his business career at the age of nine. For the next fifteen years Mr. Birney was engaged in steam road car building. In December of 1899 he accepted a job as a car builder with the Seattle Electric Company in its Seattle plant. At this time, he says, he had a wife, two children, and just $2 capital. He had to borrow his tools, for his own equipment consisted of a pocket knife, a 10-cent rule, and a pencil. His wages were $2.50 a day, and he worked ten hours.

Within ten days Mr. Birney had received two raises, in six months he took over all the pattern work, and in another six months he had become foreman of all the woodworking departments. By the end of another year he was general foreman of the entire mechanical department. In March, 1906, he was sent to St. Louis to superintend the building of 25 cars for the Seattle Electric Company, and while there he took charge of other cars being constructed for various companies under Stone & Webster management. The same year Mr. Birney was made a member of the Stone & Webster engineering division as car inspector. As stated previously it was in this position he found scope for his constructive powers.

Indianapolis Company Under G. C. Forrey, Jr., Receiver

George C. Forrey, Jr., recently appointed receiver of the Indianapolis Street Railway, is president of the Fletcher American Company, Indianapolis, and first vice-president of the Fletcher American National Bank.

His long career as an Indiana investment banker has brought him into close touch with the electric railway lines of the state and their financial problems. For a number of years, he has been a director of the Terre Haute, Indianapolis & Eastern Traction Company, and two of its leased properties, the Terre Haute Traction & Light Company and the Indianapolis & Northwestern Traction Company.

Mr. Forrey was born in Anderson, Ind. He attended Culver Military Academy and Williams College at Williamstown, Mass., (A.B. 1903). After leaving college, he became connected with the Anderson branch of the investment securities firm of Breed, Elliott

George C. Forrey, Jr.

& Harrison. Seven years later, he went to Indianapolis as vice-president of the same organization, a position which he held for eight years.

When the Fletcher American Company was organized in 1920, Mr. Forrey was appointed vice-president and general manager and in 1923 was elected president of the company as well as vice-president and director of the Fletcher American National Bank.

In addition to occupying these offices, he is president of the Belmont State Bank of Indianapolis, chairman of the executive committee of Indianapolis Abattoir, Inc., and a director of several other important local industrial institutions.

Mr. Forrey is a member of the Indiana Bankers' Association, Indianapolis Athletic Club, Columbia Club and various fraternal orders.

T. P. Pfeiffer Advertising Manager

T. P. Pfeiffer has been appointed advertising manager of the Byllesby Engineering & Management Corporation and the Standard Gas & Electric Company, Chicago.

J. W. Hicks has been appointed publicity director of the Byllesby Engineering & Management Corporation and Standard Gas & Electric Company, also remaining in charge of the publications of these companies issued for executives and employees.

D. Ernest Frame

Delaware Executive Heads Middle Atlantic Equipment Men

D. Ernest Frame, elected president of the Electric Railway Association of Equipment Men, Middle Atlantic States, at the meeting in Scranton, May 14-15, is superintendent of equipment of the Delaware Electric Power Company, Wilmington, Del. Mr. Frame's experience has not been so wide in the sense of the number of properties on which he has served, as it has been thorough and intensive. He is a product of the apprenticeship system, having served his time in the Baldwin Locomotive Works as a machinist. In 1909 he was appointed a repairman with the Philadelphia Rapid Transit Company. Four years later he was appointed foreman of the company and in 1916 was appointed district superintendent of car maintenance of the company. This position of district superintendent he resigned in 1921. For the year 1922 he was superintendent of the West Chester Street Railway. In 1923 he was appointed foreman of the Delaware Electric Power Company and in 1924 was appointed superintendent of equipment of the company, successor to the Wilmington & Philadelphia Traction Company.

✦

L. C. Whitney with Copperweld

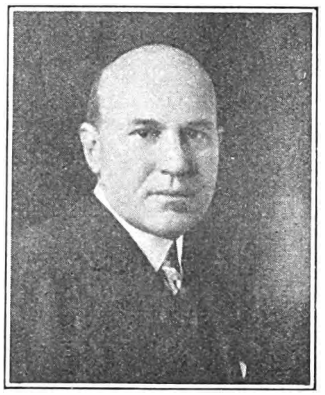
Leslie C. Whitney has joined the mill organization of the Copperweld Steel Company, Glassport, Pa., as chief metallurgist. Mr. Whitney was graduated from Lehigh University in 1922 as metallurgical engineer. For the past five years, he has been employed as assistant head of the physical laboratories for one of the largest wire manufacturers in the country. His work there covered all phases of round and flat wire production, open-hearth, rolling, drawing, and fabrication of wire products. Mr. Whitney is now supervising the installation of equipment in the Copperweld Steel Company's new research laboratory. This laboratory will combine the chemical, metallurgical, mechanical testing, and heat treating laboratories. The latest type of testing equipment is being installed throughout.

L. C. Whitney

✦

E. W. Stout Railway Receiver

Elmer W. Stout, appointed receiver of the Terre Haute, Indianapolis & Eastern Traction Company, is president of the Fletcher American National Bank, Indianapolis, the largest financial institution in Indiana and depository for several T.H.I. & E. security holders' committees. He also holds the position of vice-president of the affiliated Fletcher American Company.



Elmer W. Stout

Mr. Stout is a native of Indianapolis. He was graduated from Earlham College (Richmond, Ind.) in 1897 and from the Harvard Law School three years later. He practiced law in his home city from 1901 to 1916, during which time he acted as local attorney for the Indianapolis Water Company and several steam railroads and express companies. While attorney for the City Park Board, from 1908 to 1914, he drafted the park development program upon which the outstanding public park and boulevard system of the city of Indianapolis is founded.

His extensive legal and financial experience includes two years (1911 and 1912) as federal court receiver of the Ford, Johnson Company, Michigan City, Ind., former manufacturers of chairs and car seats.

In 1916, Mr. Stout was elected vice-president and general counsel of the Fletcher American National Bank and seven years later, in 1923, became its president. Simultaneously, he was named vice-president of the Fletcher American Company, an associated investment securities concern. In the seven years Mr. Stout has been chief executive of the bank, its deposits have more than doubled.

Mr. Stout is president of the Indiana Bankers Association and member of the Marion County and state bar associations, besides numerous Indianapolis clubs.

Departmental Activities Changed by Eastern Massachusetts

Because of the great increase in volume of work made necessary by the highly competitive nature of the transportation business, and also on account of the company's own entrance into the bus and motor coach field, it has been decided to readjust departmental activities in the Boston office of the Eastern Massachusetts Street Railway.

Effective May 15, Vice-President F. A. Cummings was assigned charge of public relations, advertising, relations between company and organized labor, and similar work as special representative of the company.

M. E. McCormick, manager of the Chelsea and Melrose-Woburn districts, has become general superintendent of transportation with headquarters in the Boston office in charge of the transportation department, reporting to A. J. Boardman, vice-president and general manager.

Albert E. Myers, superintendent of the Chelsea Division, has become manager of the Chelsea and Melrose-Woburn Divisions.

The record of Mr. Cummings with the company is well known. His work has been outstanding, best instanced, perhaps, in the extended biographies of him which were published in the issues of ELECTRIC RAILWAY JOURNAL for Oct. 25, 1924, and Sept. 15, 1923.

For the past six years Mr. McCormick has been manager of the Chelsea and the Melrose-Woburn Divisions and previously was manager of the Quincy, Salem and Lowell Divisions respectively. He worked his way up from the ranks at Bangor, Maine, where he was first employed by a street railway in 1896. He has held numerous executive positions in the mechanical and transportation departments and is thoroughly familiar with the street railway business.

After two years' service as manager of the New Brunswick Power Company at St. John, N. B., he went with the Eastern Massachusetts Street Railway in 1919, shortly after the public trustees took control of the road, and was assigned to manage the Quincy Division, from which he was promoted successively to the Salem, Lowell and Chelsea districts.

Albert E. Myers, who is succeeding Mr. McCormick as manager of the Chelsea and Melrose-Woburn Divisions, has been superintendent of the Chelsea Division for fifteen years. Prior to that time he was starter in Merrimack Square, Lowell.

William H. Giles, who was recently appointed superintendent of the Melrose-Woburn Division, will continue in the same capacity under supervision of Mr. Myers.

✦

H. R. Horton Superintendent of Instruction at St. Louis

H. R. Horton has entered the service of the St. Louis Public Service Company, St. Louis, Mo., as superintendent of instruction reporting direct to A. J. Fink, director of transportation. Mr. Horton was graduated from the University of Arkansas in 1916 with the degree of B.E.E. He immediately entered upon the graduate student course of the Westinghouse Electric & Manufacturing Company at Pittsburgh, Pa., and in 1917 became an engineer in the mechanical parts section of the railway engineering department, handling the designs of electric locomotives for mine and industrial work and for main steam road electrification. He was engaged on the pioneering work in the design and application of helical gearing, now in common use on street cars.

In 1927 he entered the employ of the Pittsburgh Railways as mechanical engineer in the instruction bureau, and on Jan. 1, 1930, became superintendent of instruction, reporting directly to Mr. Cooke, general superintendent of traffic and transportation. From that company he went to St. Louis. Mr. Horton was a member of the A.E.R.A. Committee on Employee Relations the past year, and also a member of the T. & T. Association committee The Employee, reflecting his keen interest in these subjects.

R. E. Plimpton, associate editor of *Bus Transportation,* a McGraw-Hill Publication, and a member of the editorial staff since the publication was established in 1922, has resigned, effective May 1, to assume a new position with the White Company, Cleveland, Ohio. For the past few years, Mr. Plimpton has represented *Bus Transportation* in the West with headquarters in Chicago. With the White Company, he will be in the sales promotion division as transportation engineer, conducting special investigations of bus operations.

✦

F. O. Whiteman has been appointed assistant general superintendent of the Chicago, South Shore & South Bend Railroad, South Bend, Ind., succeeding S. A. Morrison. Mr. Whiteman was formerly superintendent of service of the East St. Louis & Suburban Railway, East St. Louis, Ill.

Burton W. Marsh in Philadelphia Post Similar to His Pittsburgh Position

Burton W. Marsh

Burton W. Marsh, who was appointed as the first full-time municipal traffic engineer in the country more than five years ago by the city of Pittsburgh, became traffic engineer for Philadelphia on May 1. Through the improvements he has effected in the traffic situation at Pittsburgh and through his connection with many national committees, Mr. Marsh has become well known in the field of traffic safety engineering. The position of traffic engineer for Philadelphia was created in the 1930 budget, and comes under the administration of the department of public safety, of which Lemuel B. Schofield is director.

A downtown traffic survey, said to have been one of the most complete ever carried out as the basis for the consideration of installing a traffic signal system, was one of the steps taken by Mr. Marsh as traffic engineer of Pittsburgh. He was also influential in bringing about the establishment of the Pittsburgh Better Traffic Committee. This organization, appointed by the Mayor, is composed of business and professional leaders and city officials who are most closely concerned with street traffic problems. Mr. Marsh held the position of traffic engineer for this body, as well as for the city.

Upon the recommendation of Mr. Marsh, the Bureau of Traffic Planning was formed soon after he accepted the Pittsburgh position. This municipal department has continued to grow in personnel as well as in the appropriations made for it. For 1930, the City Council approved the expenditure of $253,400 for the bureau and its advisory body, the Better Traffic Committee. This sum is to be used for such undertakings as the erection of new traffic control equipment, signs, markings and the like, as well as to cover the salaries of the personnel. It also includes $17,500 for educational work.

Mr. Marsh was actively in charge of the design, installation and operation of the flexible progressive signal system covering 89 intersections in downtown Pittsburgh. This comprises the largest single progressive control signal system in the country. Pittsburgh's through highway system, made "fool proof" through the use of attention-compelling, flashing Neon "Stop—Through Traffic" signs, was started by Mr. Marsh last February. He was also responsible for carrying out yearly city-wide traffic counts and for starting continuous, intensive analyses of traffic accidents and development of suitable remedial measures.

Mr. Marsh is a graduate of Worcester Polytechnic Institute. Following his graduation, he attended Yale as a post-graduate student for one year. Prior to becoming traffic engineer in Pittsburgh, he was engaged for three years in municipal consulting engineering work covering traffic studies, city planning and zoning.

Mr. Marsh is vice-chairman of the engineering committee of the National Safety Council and is chairman of the program committee of the street and highway section of the National Safety Congress for 1930. He is a member of the model municipal traffic ordinance committee and several other sub-groups of the National Conference on Street and Highway Safety. He also holds memberships in the committee on standardization of traffic signs, signals and markings of the American Engineering Council, the traffic committee of the National Research Council, the traffic committee of the American Road Builders' Association, and the American City Planning Institute.

Samuel Riddle Resigns as Vice-President at Louisville

Samuel Riddle, vice-president and secretary of the Louisville Railway, Louisville, Ky., will retire from the organization on Aug. 1. Mr. Riddle went to Louisville in 1910 from the Philadelphia Rapid Transit Company to take charge of the transportation department, as superintendent of transportation, under T. J. Minary, then president.

In 1920, James P. Barnes went to Louisville as president from Schenectady, and Mr. Riddle became vice-president in charge of transportation. In 1928 he was also made secretary.

Mr. Riddle is a native of Pennsylvania. He was graduated from the engineering department of Swartmore. From 1901 to 1903 he was with the United Gas Improvement Company, and then with the transportation department of the

Samuel Riddle

United Electric Railways, Providence, R. I. From 1907 to 1909 he was general manager of the Chicago, South Bend & Northern Indiana Railway. He next went to Philadelphia. He is serving this year as president of the American Electric Railway Transportation and Traffic Association. He has not announced his future plans.

✦

L. K. Starr Resigns from Georgia Power Company

Linton K. Starr has resigned as manager of the public relations department of the Georgia Power Company, Atlanta, Ga., on account of ill health.

In 1921, Mr. Starr resigned as assistant city editor of the *Atlanta Journal* to become executive secretary of the newly formed Georgia Committee on Public Utility Information. In that post he directed the committee's activities, particularly the development of friendlier relationship between the public and corporations serving it by acquainting the one with the problems and purposes of the other. Subsequently he became connected with the Georgia Power Company. To both these posts Mr. Starr brought the advantage of a wide experience, not only in the newspaper profession, but in publicity and public relations work of all kinds. A native Georgian, a graduate of Emory University and a former student of Johns Hopkins University, he has lived practically all his life in Georgia and has been familiar from boyhood with the state and its people.

During the war Mr. Starr conducted an extensive campaign for the government to arouse interest in and encourage the support of the selective service law in Georgia. His other work has included publicity for Emory University, various conventions and a number of business enterprises. He is an experienced advertising writer.

✦

E. F. Thayer with St. Louis Public Service Company

Edwin F. Thayer, formerly with the Philadelphia Rapid Transit Company, Philadelphia, Pa., has become associated with the St. Louis Public Service Company, St. Louis, Mo., as a member of the executive staff with special duties assigned to him from time to time. Mr. Thayer went with the Philadelphia Rapid Transit Company in January, 1927, to become associated with J. M. Shaw, in charge of the public relations activities of the company. Since April, 1929, he has been new-business director of Mitten Men & Management Bank & Trust Company, and Mitten Bank Securities Corporation, Philadelphia. Before going to Philadelphia, he was a member of the editorial staff of ELECTRIC RAILWAY JOURNAL for two years with the title of assistant editor. He is by profession an engineer, having been graduated from the California Institute of Technology with the degree of B.S., in engineering and economics. Aside from serving more than a year in engineering and contracting work, Mr. Thayer's activities have all been in the field of the daily newspaper and the trade journal and in public relations. He was born in Newton, Mass., on May 7, 1901.

✦

London Delegation to Attend San Francisco Meeting

Four members of the London Companies, of which Lord Ashfield is chairman, will attend the A.E.R.A. convention in San Francisco this June. On the return trip, the party will visit the transport companies at Los Angeles, Salt Lake City, Denver, Omaha, Kansas City, St. Louis, Chicago, Detroit, Cleveland, Pittsburgh, Buffalo, Albany, Newark, Philadelphia, Baltimore, Washington, Boston and New York. The members of the party are:

George Shave, operating manager and chief engineer, London General Omnibus Company.

J. H. Williams, divisional engineer, London General Omnibus Company.

A. A. M. Durrant, assistant superintendent rolling stock, London General Omnibus Company.

L. B. Hewitt, mechanical engineer, Metropolitan Electric Tramways, Ltd.

✦

Henry Mozley, general manager of Burnley, England, tramways and buses, has retired after more than 60 years' service with transport undertakings. He has been manager of the Burnley tramways since 1882. He was president of Municipal Tramways Association in 1916-17 and has long been a member of the executive council of that body.

✦

S. J. Peterson, Omaha, Neb., formerly general claim agent for the Union Pacific Railroad, has joined the legal department of the Kansas City Public Service Company, Kansas City, Mo. Mr. Peterson was with the Union Pacific for 40 years.

"Journal" Editors Win Two Business Paper Awards

It is with pride that ELECTRIC RAILWAY JOURNAL records the accomplishments of two of its staff, George J. MacMurray, news editor, and Morris Buck, engineering editor, in winning two of the 1930 Associated Business Papers awards. Mr. MacMurray won the second award for the best editorial and Mr. Buck scored second place for the best article, series of articles or news report. First places in these two classes were won by Samuel O. Dunn, editor *Railway Age,* and Robert L. Davison, *Architectural Record.*

The objective of the A.B.P. awards is to provide recognition of outstanding excellence of business paper editorial work. It is believed the awards so dramatize editorial services that both the editors and their readers gain a wider understanding of the place and purpose of the business press in its relation to industry, trade, commerce, professional activities and specialized services.

Mr. MacMurray's editorial "The Subsidiary as a New Shibboleth," appearing in the Feb. 16, 1929, issue of ELECTRIC RAILWAY JOURNAL, dealt with the matter of political meddling through the advocacy by those outside of the industry of a subsidy as a way out for the railways, and stressed the need on the part of the railways for devising a schedule of fares that would be compensatory and yet not drive away riding. The basis for the judgment of this award was the importance of the subject, clearness of style, sound reasoning and power of influence.

Mr. Buck's series of three articles, starting with the one in May entitled "New Car Survey Shows Increased Net on Many Properties," was a survey showing how the purchase and operation of new cars had materially improved the financial status of 41 railway properties. Statistics were collected and elaborate tables and charts were presented showing the results that have been obtained before and after the introduction of new cars on these railway systems. These articles appeared in the issues of ELECTRIC RAILWAY JOURNAL for May, June and July, 1929. The awards in this class were based on timeliness, accuracy, thoroughness, originality, clearness of expression and usefulness.

✦

James J. Madden, formerly assistant secretary of H. M. Byllesby & Company and a member of the organization for twenty years, the last nine of which have been spent in the New York office where he had general charge of the accounting work of the eastern organization, has been transferred to the Chicago office as assistant secretary and assistant treasurer of Byllesby Engineering & Management Corporation and the Standard Gas & Electric Company.

✦

H. Hobart Porter has been re-elected chairman of the Engineering Foundation, research organization of the national societies of civil, mining and metallurgical, mechanical, and electrical engineers. Mr. Porter is president of the American Water Works & Electric Company, chairman of the board of the West Penn Electric Company, and vice-president of the Queensboro Gas & Electric Company. He is the director of numerous other railroad and public utility enterprises.

OBITUARY

James Scullin

James Scullin, 81 years old, pioneer street railway builder, is dead. Born in Helena, N. Y., on March 2, 1850, Mr. Scullin spent his boyhood in Potsdam, N. Y. In 1869 with his brother, Col. John Scullin, he settled in Sedalia, Mo., and when his brother received the contract to build a spur for the Missouri-Kansas-Texas Railway between Sedalia, Mo., and Parsons, Kan., James acted as superintendent of construction. In the late '70s Mr. Scullin located in St. Louis, being active in the development of street railways there. For a while he was superintendent of the so-called Scullin Lines. He retired from this work in the late '90s. He served as a deputy surveyor of customs until elected city marshal. At the end of his second term in that office in 1909 he entered the real estate business. He retired from active business fifteen years ago.

✦

Ambrose Clogher

Ambrose Clogher, who had practiced law in New York since 1920, died suddenly on April 24 at the age of 58. Since establishing his home in New York, Mr. Clogher had represented the New York Railways, the Fifth Avenue Coach Company and other transportation interests before the Appellate Division and the Court of Appeals.

Early in the World War, Mr. Clogher went overseas with the American Expeditionary Force, and from 1918 to 1920 served under the Judge Advocate General of the American Army, presiding over military courts and engaging in other legal work with the American forces.

Born at Washington Mills, N. Y., Mr. Clogher was graduated from Manhattan College, this city, in 1894, and began his legal career in Massachusetts six years later.

✦

W. Emlen Roosevelt

W. Emlen Roosevelt died on May 17, in New York, at the age of 73. Though never so much before the public eye as other members of the Roosevelt family, W. Emlen Roosevelt was one of the most prominent figures in Wall Street, and besides his many activities in railroads, industry and public utilities he was a partner for 52 years in the investment firm of Roosevelt & Sons, one of the oldest houses on the Street.

Unlike other members of the Roosevelt family, there is no record that W. Emlen Roosevelt ever sought or held a public office. He was born in New York and after he was graduated from Harvard entered the firm of Roosevelt & Sons, in which he was a partner at the time of his death. This firm was established in 1797. Theodore Roosevelt, the father of late President Roosevelt and an uncle of W. Emlen Roosevelt, was a partner in the firm.

W. Emlen Roosevelt was widely affiliated with business and banking. He was chairman of the Board of All American Cables, Inc., and a director of Third Avenue Railway, Westchester Electric Railroad, Kingsbridge Railway, Forty-second Street, Manhattanville & St. Nicholas Avenue Railway, New York City Interborough Railway, Belt Line Railway, Union Railway, Dry Dock, East Broadway & Battery Railway, Hastings Railway, New York, Westchester & Connecticut Traction Company, Southern Boulevard Railway, and the Yonkers Railroad.

✦

Thomas A. Cross

Thomas A. Cross, vice-president in charge of claims for the United Railways & Electric Company, Baltimore, and for 39 years prominently identified with the railway system in Baltimore, died on May 13. He succumbed to pneumonia, with which he was attacked less than a week before his death. Mr. Cross was 68 years old. He was unmarried.

Governor Ritchie, of Maryland, and many other men prominently identified

Thomas A. Cross

with the official and business life of the city and state acted as honorary pallbearers at the funeral on May 15.

Mr. Cross was president and chairman of the board of the United during the war. Following the war he was succeeded by Charles D. Emmons, who recently resigned. He was nationally known in the utility field.

Mr. Cross entered railway work in Baltimore in 1891, as a lineman for the old North Avenue Traction Company, one of the first successful trolley lines in the country. Two years later he became connected with the Baltimore Traction Company, which operated the old Druid Hill Avenue cable line. After another two years some of the lines of the city were merged in the Consolidated Railway, and Mr. Cross became superintendent of overhead lines. He also served the company in other capacities.

When the United Railways & Electric Company was formed, Mr. Cross was made general manager. In April, 1911, he became second vice-president and in 1917 succeeded William A. House as president and chairman. For a time after he was succeeded as president by Mr. Emmons, he continued as chairman of the board. Upon the resignation of James R. Pratt to enter private business Mr. Cross became vice-president in charge of claims, filling the office until the time of his death.

Mr. Cross was born in Prince George's County, Md. He was graduated from the Maryland Agricultural College, now the University of Maryland. For a short time after he was graduated and before he entered the street railway field, he was connected with a commercial organization.

✦

Seth W. Baldwin

Seth W. Baldwin, formerly attorney for the Connecticut Company, New Haven, Conn., died suddenly on May 14, in Bethany, Conn. He had been in ill health since early in February, but his death, which was caused by a heart attack, was entirely unexpected. Mr. Baldwin had been connected with the electric railway industry for many years, and was an active participant in the work of the American Electric Railway Claims Association.

Mr. Baldwin was born in Naugatuck, Conn., Dec. 7, 1880. He was graduated from Yale, A. B. 1904, and LL.B. 1906. He was connected with Watrous & Day, New Haven, 1906-07; was claims attorney for the New York, New Haven & Hartford Railroad for Connecticut and New York, 1907-14, and had been attorney for the Connecticut Company since 1914. He was also president of the Morris Cove Company. Mr. Baldwin was awarded the Brady medal for achievement in safety and sanitation on street railways by the American Museum of Safety in 1916.

Funeral services were conducted at Battell Chapel, Yale University, on May 17, the remains being interred in the family plot at Mountain Grove Cemetery, in Naugatuck, Conn.

✦

William A. Whitney, general manager of the Utah-Idaho Central and the Utah Rapid Transit Railroads for six years prior to June, 1923, died in San Francisco on April 17. In 1923 he was made active head of the Mount Hood and Sumpter Valley Railroads in Oregon, as well as manager in charge of operations of the Oregon Lumber Company mills in Oregon and Washington. He continued with the two Utah electric roads at that time as vice-president and director. He was active head of the Eccles lumber and railroad interests in Oregon and Washington. Mr. Whitney went to Ogden as head of the electric roads in 1917 from the position of superintendent of transportation for the Union Pacific. Prior to that time he was superintendent of several different divisions of the Union Pacific and from 1911 to 1914 was superintendent of the Sacramento and Oakland divisions.

✦

Charles R. Johnson, an employee of the Triple Cities Traction Company, Binghamton, N. Y., whose service dated back 45 years to the days of the horse car, is dead. He was 83 years old. Mr. Johnson was born in Glen Castle and came to Binghamton 50 years ago. He entered railway work in the days when separate companies served various parts of the city by horse car and he drove over South Side and North Side lines. Later these lines were amalgamated in the Binghamton Railway, and with the coming of the trolley he was assigned operating duties, a place he held until a few years ago, when less exacting duties were arranged for him by the Triple Cities Traction Company, successor to the Binghamton Railway.

INDUSTRY MARKET AND TRADE NEWS

Milwaukee Company Receives Ten Two-car Trains

Ten new two-car trains especially designed for suburban service, have been purchased from the St. Louis Car Company by the Milwaukee Electric Railway & Light Company for its South Milwaukee line. The first of these trains began operation in rush-hour service between the Public Service building and Grange Avenue, Cudahy, effective Tuesday, April 29. Their operation through to South Milwaukee is contingent on arrangement of a loop track in that suburb.

The new trains are of the most modern type, with steel body construction, streamline appearance and latest features for passenger comfort. They are built on the three-truck principle, with a passageway between cars open for use at all times. Entrance and exit doors are at the front end of the second car, and an emergency exit is provided at the front of the forward car. Special truck construction reduces the over-all height of the new trains, and the exterior color scheme of chrome yellow and green accentuates their long, low appearance. Interior head-room has not been reduced, however, and seats are provided for 119 passengers. Smoother riding qualities are calculated to result from the special form of suspension and lower center of gravity.

The forward car has leather upholstery, and the rear car, on which smoking will be permitted, has standard rattan seats. Otherwise the two cars are identical, with electric heating, special insulation, semi-indirect lighting, rubber-tile floor covering, wide aisles and improved exhaust ventilators. Improved acceleration and braking are provided, with six 50-hp. motors, as well as air brakes applying to all twelve wheels. The trains are of the single-end type, requiring loop facilities at the terminals of the line.

Ten Cars for Knoxville Power & Light Company

Ten double-truck, double-end cars of the arch-roof type, with all steel bodies, have been ordered by the Knoxville Power & Light Company from the Perley A. Thomas Car Works, Inc., of High Point, N. C., delivery to be made some time in August.

Equipment specifications are as shown below:

Length over all	39 ft. 4 in.
Length over body posts	29 ft. 3 in.
Truck wheelbase	20 ft. 0 in.
Width over all	8 ft. 5 in.
Air brakes	Westinghouse Air Brake Co.
Armature bearings	Plain
Axles	A.E.R.E.A. standard type E2
Car signal system	Faraday
Compressors	Westinghouse DH 16
Conduit	Flexible
Control	General Electric K-75
Curtain fixtures	Adams & Westlake
Curtain material	Pantasote, double faced
Destination signs	Keystone
Door mechanism	National Pneumatic Co.
Doors	Folding
Fare boxes	Johnson
Finish	Enamel
Floor covering	Linoleum
Glass	Plate
Hand brakes	Peacock staffless
Hand straps	Buffalo type
Heaters	Consolidated Car Heating Co.
Headlights	Golden Glow NRM 96
Headlining	Haskelite
Interior trim	Cherry
Journal bearings	Plain
Journal boxes	A.E.R.E.A. standard
Motors, four	G. E. 265
Painting scheme	Cream and orange
Roof material	Haskelite, canvas covered
Sash fixtures	Adams & Westlake Co., brass sash
Seats	Hale & Kilburn, No. 392-A
Seating material	Green plush
Steps	Folding
Step treads	Kass
Trolley	Ohio Brass Co.
Trolley base	R. D. Nuttall Co., U. S.-20
Trucks	Brill 76-E-1-X
Ventilators	Nichols Lintern Type C
Wheels, type	Steel, diameter 26 in.
Wheelguards or fenders	H. B. Wood slat

Delivery of Detroit Cars to Start in June

Additional details of the 130 cars recently ordered from the St. Louis Car Company by the City of Detroit Department of Street Railways are now available. The new cars, which will be of semi-steel construction of the arch-roof type will have an over-all length of 48 ft. 5 in. They will be single-end, double-truck, front-entrance, center-exit, arranged for two-man operation. Seats will be provided for 52 passengers. It is understood that the order for air brakes, control apparatus, and motor equipment, of which there will be four to each car, will be divided equally between the Westinghouse and General Electric Companies. Steel wheels of 26-in. diameter will be provided.

Other specifications are as follows:

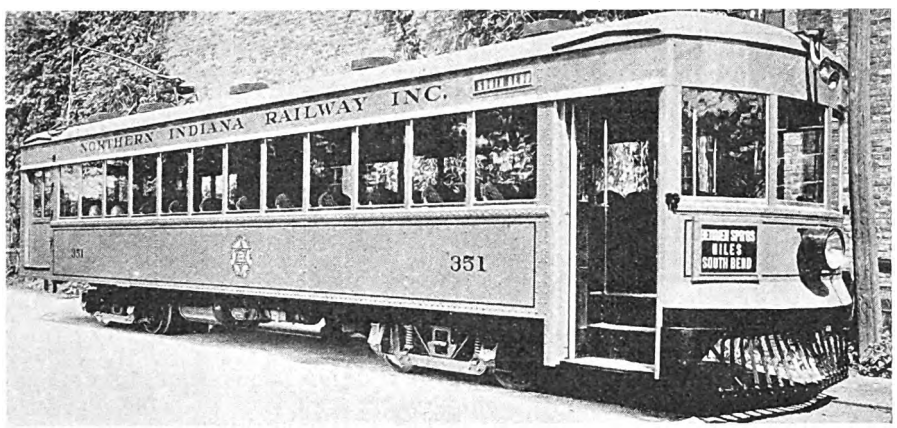
Curtain fixtures,
Curtain Supply Company's No. 88
Curtain material...Double faced Pantasote
Glass.....Libby-Owens plate
Headlining.....⅜ in. Agasote
Lamp fixtures,
Electric Service Supply Company
Sash fixtures.....O. M. Edwards, metal
Seating material,
Full grain brown Spanish leather
Step treads.....Kass, No. 14
Trolley catchers.....Ohio Brass No. 13141
Trolley bases.....Ohio Brass Form 5
Ventilators....12 Railway Utility Company
Honeycomb vent
Wheelguards .....H-B type

Mercedes Benz Company, Inc., announces the appointment of the National Railway Appliance Company, 420 Lexington Avenue, New York City, as their representative for Diesel engines, and buses and trucks equipped with Diesel motors.

New Interurban Cars for Northern Indiana Railway

Carrying out a rehabilitation program promised at the time of the company's reorganization, the Northern Indiana Railway, Inc., South Bend, Ind., has ordered ten interurban cars from the Cummings Car & Coach Company, Paris, Ill. The cars, which are designed for one-man operation and which are expected to attain a speed of 60 m.p.h., will be ready for delivery by June 1, and will replace the present interurban cars which carry crews of two men.

The new cars are well proportioned, with streamline body design, and are divided into three compartments, main passenger, smoking, and baggage, with a total seating capacity of 51, including the upholstered folding seats in the baggage section. Inside finish is walnut, with chromium plated metal trimmings. Total weight is 42,000 lb. Over-all length is 47 ft. 2 in., width over-all, 8 ft. 10 in., and height, rail to trolley base, 10 ft. 8 in.



One-man cars of attractive design replace heavier rolling stock on Northern Indiana Railway

Motor and control equipment consists of four Westinghouse No. 516, 50-hp. motors, and K-75 tapped field control. Westinghouse air brakes and safety control are provided. Trucks are Cummings Car & Coach Company's No. 64, equalizer type, with 4¼ in. by 8 in. journals and 28-in. wheels. Wheelbase is 5 ft. 6 in. Other details of specifications are as follows:

Armature bearings	Plain
Car signal system	Faraday
Curtain fixtures	Excel
Curtain material	Pantasote
Destination signs	Keystone
Door mechanism,	National Pneumatic Company
Doors,	Front folding; rear sliding for baggage
Floor covering	Tucolite
Gears and pinions	Westinghouse
Hand brakes	Pittsburgh No. 35
Heaters	Consolidated
Headlight	Ohio Brass Company
Headlining	Agasote
Journal boxes,	Cummings Car & Coach Company
Lamp fixtures	Dayton, dome type
Paint,	Enamel outside; strain and varnish inside
Roof material	Wood, canvas covered
Sash fixtures	A&W brass, chromium plated
Seats	American Wicker Works
Seat spacing	34 in.
Seat covering	Plush and leather
Trolley retriever	Knutson No. 5
Trolley base	Ohio Brass Company
Ventilators	Railway Utility Company

Specifications of Baltimore Cars

Complete specifications of the 150 cars now under construction for the United Railways & Electric Company, of Baltimore, are now available. As previously stated in this magazine, 100 of the bodies are to be constructed by the J. G. Brill Company, at Philadelphia, while 50 bodies will be supplied by the Cincinnati Car Corporation. Equipment specifications, which are substantially the same in both orders, are as follows:

Air brakes	Westinghouse Traction Brake Company
Armature bearings	Plain
Axles, 4¼ in.	Bethlehem Steel Company
Car signal system	Electric Service Supply Co., No. 27801 CB push button
Compressors	Westinghouse DH-20
Conduit	Flexible
Control	75 Westinghouse "VA -75 GE. "PCM"
Couplers	Portable draw bar
Curtain fixtures	Adams & Westlake No. 88
Curtain material	Pantasote double face No. 80
Destination signs	Hunter
Door mechanism	National Pneumatic Company
Doors	Folding
Energy saving device	Economy meter
Fare boxes	Johnson
Floor covering	3/16-in. battleship linoleum
Gears and pinions, Tool Steel Gear & Pinion Company	
Glass	Sheet glass, double thick
Hand brakes	Peacock staffless
Heaters	Railway Utility Company's panel type
Headlights	Electric Service Supply Co. FH-916
Headlining	Agasote
Interior trim	Wood and metal
Journal bearings	J. G. Brill, plain
Journal boxes	J. G. Brill
Lamp fixtures	Electric Service Supply Co., dome
Motors, four, Westinghouse 516-GE-301, inside hung	
Registers, Johnson Electric and International R-7	
Roof type	Arch
Roof material	Wood, canvas covered
Safety car devices, National Pneumatic Company	
Sash fixtures, Adams & Westlake—O. M. Edwards	
Seats	J. G. Brill
Seat spacing	31½-in.
Seating material	Leather
Slack adjusters	Brill automatic
Steps	Stationary
Step treads	Kass
Trolley catchers	Earll No. 10
Trolley base	Ohio Brass Company
Trolley wheels	Ohio Brass Company
Trucks	J. G. Brill, 177-E 1
Ventilators	Railway Utility Company
Wheels, type	Rolled steel, diameter 26 in.
Wheelguards or fenders	H. B. life guard

Recent Bus Orders and Deliveries

Conspicuous among recent orders for automotive equipment is that of the City of Detroit Department of Street Railways for six trolley buses and 50 40-passenger, gas-electric, metropolitan type buses. The trolley buses will be from the Twin Coach Company, and delivery is expected by the first of June, but the order for buses is being held up pending further consideration by the City Council.

Twin Coach Company has made delivery of 29 trolley buses and two urban-type coaches to Chicago Surface Lines. Los Angeles Motor Coach Company and the San Diego Electric Railway have each received two of the Twin Coach urban-type buses.

Recent White deliveries include one Model 65 bus to the Denver Tramway Corporation, five Model 65A buses to Montreal Tramways, and one 65A bus to Southern Public Utilities, of Winston-Salem, N. C. The Boston, Worcester & New York Street Railway has placed in express service, Boston to Worcester, five 37-passenger de luxe White buses, while four 29-passenger buses have been added to the Boston-New York service.

Among deliveries reported by the Mack-International Motor Truck Corporation are two Model AB 25-passenger buses for city service to the Lincoln Traction Company, Lincoln, Neb., one bus of similar type to the Fonda, Johnstown & Gloversville Railroad, one Model AB 23-passenger bus for intercity service to the Oklahoma Union Railway, Tulsa, Okla., and one Model BC 33-passenger, city-type bus to the Nashua Street Railway, Nashua, N. H.

New Cars for Mobile, Ala.

The Mobile Light & Railroad Company recently received seven all steel, one-man, single-truck cars for city service, of which four were supplied by the Perley A. Thomas Car Works, Inc., and three by the American Car Company, of St. Louis. The Thomas cars are of the double-end type, while those supplied by the American Car Company are single-end. Dimensions and weight are substantially the same, but detail specifications differ in certain respects.

The cars will have an over-all length of 29 ft. 9 in., an over-all width of 8 ft. 3 in., and a truck wheelbase of 8 ft. 6 in. Weight will run about 19,000 lb. Seating capacity is eighteen passengers.

Specifications are as follows:

Builder of car body	Perley A. Thomas Car Works	American Car Company
Air brakes	Westinghouse Air Brake Company	Westinghouse Air Brake Company
Armature bearings	Plain	Roller
Axles	A.E.R.E.A. standard	Brill
Car signal system	Faraday (Electric Service Supply Company)	Faraday
Compressors	Westinghouse DH-16	Westinghouse DH-16
Conduit	Flexible	Flexible
Control	General Electric K-35	Westinghouse K-63-G
Couplers		
Curtain fixtures	Adams & Westlake	Curtain Supply Co. No. 49
Curtain material	K-2 Pantasote	K-2 Pantasote
Destination signs	Keystone	Hunter
Door mechanism	National Pneumatic Co.	National Pneumatic Co.
Doors	Folding	Folding
Energy saving device		
Fare boxes	Johnson DM-4	Johnson DM-4
Finish	Enamel	Vitralite enamel
Glass	Plate	Plate
Hand brakes	Drop handle type	American Car Company
Hand straps	National Railway Appliance	None
Heat insulating material		
Heaters		
Headlights	Ohio Brass type WDF	Crouse-Hinds No. 28519
Interior trim	Mahogany	Mahogany
Journal bearings	Plain	Plain
Journal boxes	A.E.R.E.A. standard	Brill
Motors	G. E. 265	Westinghouse 510-E
Painting scheme (color used)	Traction orange	Traction orange
Roof type	Arch	Arch
Roof material	Wood, canvas covered	Wood, canvas covered
Safety car devices		
Sash fixtures	O. M. Edwards A-525-6	O. M. Edwards A-525-6
Seats		Brill "Waylo" reversible
Seat spacing		28 in.
Seating material	Cherry	Mexican mahogany
Slack adjusters		Brill, air operated
Steps	Folding	Folding
Step treads	American Abrasive	Feralun
Trolley	Earll No. 10	Earll No. 10
Trolley base	Nuttal 20-A	U. S. No. 20-A
Trolley wheels	G. E. Feist	G. E. Feist
Trucks	Brill 79-E-2	Brill 79-E-2
Ventilators	Brill exhaust type	Brill exhaust type
Wheels, type	Rolled steel Diam. 26 in.	Rolled [illegible]
Wheelguards or fenders	H. B.	H. B.

Electric Railway Material Prices—May 24, 1930

Metals—New York

Copper, electrolytic, delivered, cents per lb.	13.00
Lead, cents per lb.	5.50
Nickel, cents per lb., ingot	35.00
Zinc, cents per lb.	4.95
Tin, Straits, cents per lb.	31.75
Aluminum, 98 to 99 per cent, cents per lb.	24.30
Babbitt metal, warehouse, cents per lb.:	
Commercial grade	41.00
General service	31.00

Bituminous Coal

Smokeless mine run, f.o.b. vessel, Hampton Roads, gross tons	$4.20
Somerset mine run, f.o.b. mines, net ton	2.00
Pittsburgh mine run, Pittsburgh, net ton	1.40
Franklin, Ill., screenings, f.o.b. mines	1.55
Central, Ill., screenings, f.o.b. mines	1.45
Kansas screenings, Kansas City	1.85

Track Materials—Pittsburgh

Standard steel rails, gross ton	$43.00
Railroad spikes, drive ⅝ in. and larger, cents per lb.	2.80
Tie plates (flat type), cents per lb.	2.08
Angles bars, cents per lb.	2.75
Rail bolts and nuts, cents per lb.	3.90
Steel bars, cents per lb.	1.80
Ties, white oak, Chicago, 6 in. x 8 in. x 8 ft.	$1.40

Hardware—Pittsburgh

Wire nails, base per keg	$2.20
Sheet iron (24 gage), cents per lb.	2.60
Sheet iron, galvanized (24 gage), cents per lb.	3.25
Galvanized barbed wire, cents per lb.	2.85
Galvanized wire, ordinary, cents per lb.	2.80

Waste—New York

Waste, wool, cents per lb.	10.00 to 15.00
Waste, cotton (100 lb. bale), cents per lb.:	
White	9.00 to 12.00
Colored	6.00 to 10.00

Paints, Putty and Glass—New York

Linseed oil (5 bbl. lots), cents per lb.	14.2
White lead in oil (100 lb. keg), cents per lb.	13.75
Turpentine (bbl. lots), per gal.	0.54
Putty, 100 lb. tins, cents per lb.	5.725

Wire—New York

Copper wire, cents per lb.	14.00
Rubber-covered wire, No. 14, per 1,000 ft.	$5.30
Weatherproof wire base, cents per lb.	14.75

Paving Materials

Paving stone, granite, 5 in., f.o.b.: New York—Grade 1, per thousand	$150.00
Wood block paving 3½, 16 lb. treatment, N. Y., per sq.yd., f.o.b.	2.70
Paving brick 3½x8½x4, N. Y., per 1,000 in carload lots, f.o.b.	50.00
Paving brick 3x8½x4, N. Y., per 1,000 in carload lots, f.o.b.	45.00
Crushed stone, ¾-in., carload lots, N. Y., per cu.yd., delivered	3.40
Cement, Chicago, in carload lots, without bags, f.o.b.	1.95
Gravel, ¾-in., cu.yd., delivered New York	3.40
Sand, cu.yd., delivered New York	2.15

Old Metals—New York and Chicago

Heavy copper, cents per lb.	10.25
Light copper, cents per lb.	8.75
Heavy yellow brass, cents per lb.	5.80
Zinc, old scrap, cents per lb.	2.25
Lead, cents per lb. (heavy)	3.75
Steel car axles, Chicago, net ton	$16.25
Cast iron car wheels, Chicago, gross ton	14.25
Rails (short), Chicago, gross ton	16.00
Rails (relaying), Chicago, gross ton (65 lb. and heavier)	28.50
Machine turnings, Chicago, gross ton	7.50

Electric Railway Journal

Consolidation of
Street Railway Journal and Electric Railway Review
A McGraw-Hill Publication—Established 1884

JOHN A. MILLER, JR., *Managing Editor*

New York, June 14, 1930
Volume 74 *Number 7*

Annual Convention Number

Improving Design to *Improve Service*

TODAY, more than ever before, the interest of electric railway men is directed to improving service by improving the design of equipment and physical plant. Among the many problems before the industry none is more vital than this. True, traffic congestion and control is a live issue. Important questions of valuation and rates of fare are now under consideration. Relations between management and employees are being studied intensively. Methods of publicity and merchandising are prominent in the minds of many operators. Means to cut costs are receiving concentrated attention. But the cornerstone upon which rests the whole structure of electric railway progress is the design of equipment and physical plant.

Many advances have been made in recent years. More will be made in the years to come. Where are these trends leading? Are these various improvements separate and unrelated, or are they parts of a definite and correlated program? While at first glance the relationship between the many different developments may not be evident, deep down below the surface practically all of them will be found to have the common objective—to improve the quality of the transportation service rendered.

OF PARTICULAR interest at the present time are the improvements being made in the electric rail car. For some years the industry has been awake to the need of modernizing its rolling stock. While other forms of transportation had undergone revolutionary alterations, the car, the heart of the electric railway, remained unchanged. It was realized that the electric railway could not continue to hold its rightful place in the transportation field unless the car was brought up to date.

Modernization plans inaugurated during this period are now beginning to bear fruit. Great strides have been made in improving the appearance of cars. Certainly the utility of the vehicle is not impaired by making it attractive. Many improvements have been made which provide greater comfort and safety for the passenger. Operating speeds have been increased by means of more rapid acceleration and braking. Effective means to lessen vibration and noise have been developed by scientific study. Though these may be small things in themselves, in the aggregate they constitute an important contribution toward improving the quality of service.

LESS SPECTACULAR, perhaps, but none the less important have been the improvements in track construction methods and machinery. Demands on the track structure under conditions existing today differ widely from those of a few years ago. To meet these new conditions, engineers have effected far-reaching changes in design. Likewise, in the field of power conversion and distribution for the electric railway, a variety of equipment is available today which is vastly more efficient and more economical than that in general use a decade ago.

Spectacular growth of our cities has created new problems. Population is increasing and at the same time is spreading over a much wider area. The distance between home and work is becoming ever greater. Heavier demands have been placed upon existing rapid transit facilities, and new facilities have become necessary. Efficient operation of these lines demands improved equipment.

Along with the intensive service in the congested area, there has developed a demand for service in many less densely populated districts. Here the motor bus and the trolley bus have entered the picture. Like the electric car, both have undergone many changes in design which have greatly increased their usefulness.

From every standpoint demands made upon public transportation service are far different today from those of a few years ago. These conditions present a challenge to both the transportation operator and the manufacturer of equipment. That the challenge to improve service will be met there can be no doubt. But that it shall be successfully met demands untiring effort to improve design.

How the Convention Will

Benefit the Industry

By

PAUL SHOUP

President Southern Pacific Company
President American Electric Railway Association

THERE is no activity in our national life more important and all-concerning than transportation. For this reason the entire country has a direct interest in the 49th Annual Convention of the American Electric Railway Association. More than 2,000 members of the association from all over the United States and Canada will gather in San Francisco June 23 to 26. These men, actively engaged in the transportation of people and merchandise, will bring to the convention the story of their problems and accomplishments and from the discussion of these topics all of us will receive helpful suggestions and healthy stimulation.

A convention is an institution for the exchange of ideas. The program of the 49th Annual Convention of the American Electric Railway Association covers a wide range of important and timely subjects. Those who come may be sure that the time given to attending this gathering will be well spent.

The electric railway industry should benefit by this convention in other ways as well as from the discussion of its problems. Among those who attend the convention will be representatives not only of the industry itself but also of many western communities. Governors of states, mayors of cities, members of legislative bodies, educators and other leaders in public life have been invited to attend and we have reason to believe that many of these invitations will be accepted—with benefit, I am sure, both to the electric railway industry and to the communities they represent. Understanding is an important factor in progress and there is no better way to develop understanding than by giving the party of the other part a seat at your council chamber.

The development of closer acquaintanceship among ourselves is another benefit of a gathering such as this convention. In the days of the Don, California hospitality was a sacred rite. Those were the days of which the historian Bancroft wrote: "A man could ride from San Diego to Sonoma without a coin in his pocket and never want for a roof to cover him, a bed to sleep on, food to eat, and even tobacco to smoke." In those days transportation facilities were of the four-legged variety and there were no hotels. The visitor who galloped up to the door in the late afternoon expected to spend the night as a guest—and was never disappointed. His horse or mule was given a rubdown and a well stocked stall. The visitor was escorted to the guest chamber where his host waited on him with a basin of water and clean towels. These the host carried himself, but a queue of servants walked behind the master to indicate that had he not wished to show his guest the courtesy of personal service, he could have delegated its performance to hired retainers. When the guest awoke in the morning he found on his bedroom table a clean shirt and a jar containing money—both for his use if he needed them. If his horse was still tired he was given another horse which he exchanged for his own later on the return journey.

On this and similar old Spanish customs, California hospitality was founded. It is the same today as it was 200 years ago, and judging by the plans which have been made for entertaining the visitors to the A.E.R.A. convention, they will long remember their visit to the "land of the Don."

Co-operative Effort

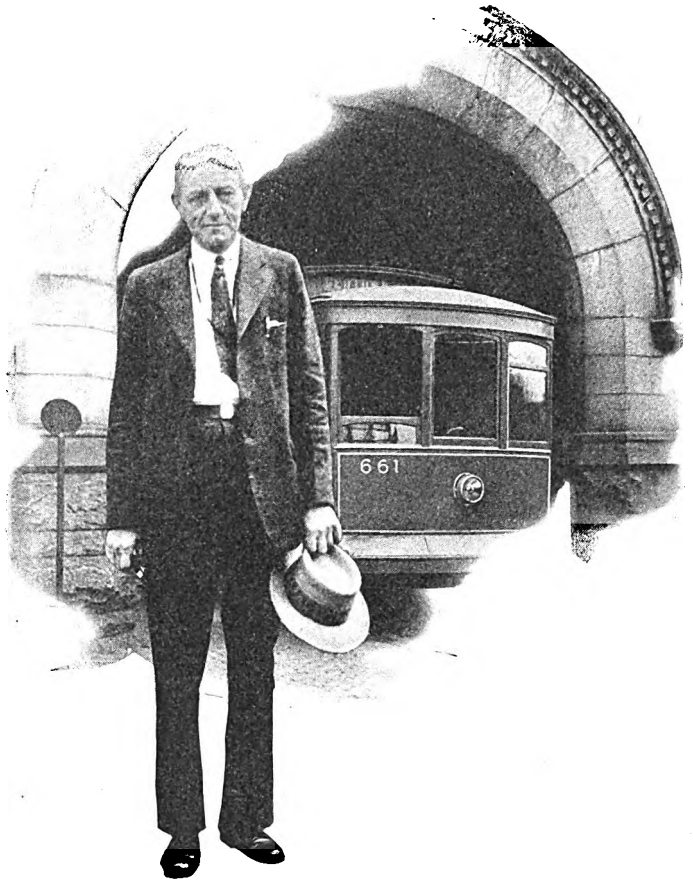
Is Greatest Need

By

J. H. HANNA

President Capital Traction Company

First Vice-President
American Electric Railway Association



SERVICE furnished by the urban and suburban transportation companies is absolutely essential to the welfare of American cities, and if it should be eliminated or seriously crippled the public as a whole would suffer grievously. The business is no longer a monopoly, if it ever was, and while unregulated competition should and must be curtailed, the industry's plans for the future must be based on meeting rather than eliminating competition.

There are probably no more important matters affecting urban transportation agencies today than traffic congestion and the various plans for preventing or correcting it. Unfortunately, many of the studies and plans for improving the traffic situation in cities have been based on a consideration of the movement of vehicles rather than the movement of passengers, resulting in entirely inadequate provision being made for mass transportation vehicles. Parking regulations, traffic lights and signals should be considered on a basis of the greatest good to the greatest number of individuals to be transported. An attempt to handle mass transportation by individual vehicles, either private cars or taxicabs, would result in practical stagnation unless street capacities are doubled or quadrupled.

It is noticeable that in those cities where engineers of transportation companies take an active part in the drafting of traffic regulations and establishing signal systems, the results have been much more satisfactory than in cities where the companies' assistance has not been utilized.

The American Electric Railway Association can do nothing which will be of more benefit to its members and to the public at large than to impress upon municipal authorities and city planners the fact that mass transportation vehicles must be given more consideration in traffic regulation. The vast majority of people now depend upon public transportation service and must continue to do so if traffic conditions are not to get very much worse instead of improving.

All of these factors emphasize the importance of co-operative effort and call attention to the activities of the association and their importance to every operating and manufacturing company. The present tendency in the association's work is towards detailed technical study of the various elements of the business and it is through such detailed technical study that the industry can improve the value and attractiveness of the service which it renders, and thereby get back customers it has lost.

The Committee on Fare Structures, recently established, has great possibilities. The flat fare for city companies has been considered practically inviolate in spite of numerous efforts made to break away from it in the last ten or twelve years. There is no doubt that the flat fare is economically unsound and has driven away much profitable business. Many and varied plans have been suggested and tried out for the establishment of a more scientific fare scheme but none has so far been entirely satisfactory. It is quite possible that this committee's work may go far towards helping solve the industry's difficulties. In any event, the necessity for co-operative effort has never been so great as at the present time.

Market Street, with its four parallel tracks, is the main business thoroughfare of San Francisco

DESIGN of street cars is undoubtedly one of the important factors in revamping service to satisfy more nearly present-day demands. Any increase in comfort features, consistent with carrying capacity and loading requisites, is of vast importance. Any improvements contributing to speed, noise reduction and smoothness likewise raise the street car ride in the estimation of the public.

IMPROVEMENT *in the* RIDE

Is the Most Effective Stimulant of

Public Interest

By

CHARLES GORDON

Managing Director
American Electric Railway Association

ALTHOUGH there is much room for optimism in the electric railway industry at the present time, prompted by the general feeling that its major problems are being attacked with renewed vigor, we should not minimize the great task before us. Eleven years have elapsed since the close of the war, but this industry has not been able to balance its operating budget in the true sense of the word. Its net earnings have been subnormal; the return upon its capital investment has been inadequate, and it has lost ground in number of passengers carried in relation to population increase. In consequence of these conditions, new capital can be secured only with difficulty and at high cost. There is a general feeling, not only in the minds of bankers and investors, but also on the part of the public at large, that the future of the industry is highly problematical.

News of the abandonment of electric railway lines is widely disseminated, and the significance thereof magnified beyond all reason. A large section of the public believes that the future useful life of our surface transportation systems will be comparatively short, and that the electric railway car will soon disappear as the stage coach and the canal boat have done. This lack of confidence in the future of our industry affects us adversely in attempting to attract the capital needed for refinancing and for improvements.

Pleas for public co-operation with respect to franchises, taxes and traffic regulations, as well as for consideration of public along with private transportation in city planning and highway construction do not attract public interest because the average man is not inclined to be interested in an industry which he considers obsolete. There is a strong tendency to overlook the plight of community transportation and of the vital part which it plays in the life of modern cities. This is attributable in large measure, if not entirely, to the impression of obsolescence which is created by the character and condition of the equipment which we operate.

All studies of the requirements of the industry lead to the inevitable conclusion that the cars which we operate represent an important phase of our problem. The industry has for several years been aware of the evils attendant on the operation of the large number of obsolete and heavy cars that are in service. In considering the economics of replacing a large proportion of its present equipment, however, it was faced with the fact that the type of equipment currently offered did not

Digitized by Google

meet present-day traffic requirements to the degree which would warrant the investment. Nor was the evidence as to the economies which would result from the operation of this equipment sufficiently impressive to lead to the belief that replacement with such rolling stock would re-establish the railways upon a firm foundation.

Three interested groups must be considered in any study of the requirements of present-day transportation equipment: the public, the electric railway and the manufacturer. Of all the objectives to be attained in car design, probably the most important are those which are necessary to meet the demands of the public. In this respect, the electric railways must compete with individual automobile transportation, and their cars must be suitable for that purpose. They must meet the requirements of modern conditions, both in their performance and in the impression which they make on the public. They must be in keeping with their surroundings in the modern city. They must be able to keep up with other traffic on the street, and must meet the demand for quick transportation. They must, by their very appearance and by the impression which they make on an observer, create the desire to ride in them. There must not be the slightest hint of being out of style. The American public refuses to be associated with anything which even gives the impression of being out-of-date, and it will tolerate such a thing only so long as it is forced to do so. Future rolling stock must be quiet in operation. It must be smooth and pleasant to ride in. It must be comfortable, convenient, and easy to use. It must, in fact, meet the automobile on its own ground, for the public has become automobile-minded.

From the standpoint of the railway, it must be able to accomplish all these things at the lowest possible cost. In fact, the cost must be far below that of individual transportation. Managements are faced with the problem of providing satisfactory service with a fare which, in most instances, is inadequate to provide the revenue needed to insure adequate returns to investors. Therefore, the question of reducing cost is a vital one to the continued operation of their systems. Considering cost, the car must be light, but care must be taken not to reduce the weight below the point where the high initial cost, through the use of expensive alloys and other costly materials, overbalances the saving resulting from the lighter weight made possible thereby. Its structure must be as simple as is consistent with necessary strength. The possibilities of weight and resulting cost reductions seem to be the most attractive in trucks, motors, electrical control apparatus, braking equipment and miscellaneous apparatus. The many specialties which go into a car, such as seats, doors, trolley retrievers, headlights, etc., seem to offer further possibilities for simplifying the design and reducing the cost.

From the manufacturer's point of view, the many improvements demanded must be made in face of a continual clamor for reduced first cost. The very conditions under which cars are built and sold militates against the accomplishment of this objective. Car building has been largely a contracting rather than a manufacturing business. A builder influences the details of construction, but rarely sponsors the complete unit as a distinctive manufactured product. It has been suggested that the car builders should take the initiative in developing cars to be sold as other manufactured products are sold. On the other hand, some builders hold that street cars cannot be sold in that way because the operating companies will continue to insist upon specifying their own design. Only experience can prove or disprove this point. It is worthy to note, however, that bus manufacturers have succeeded in selling to transportation companies, many of them electric railways, models of their own design.

To meet the public demand for speed in transportation, cars are needed which, as nearly as possible, will accelerate and stop as rapidly as the best powered private automobile on the street and which have a sufficiently high free-running speed to hold their place in traffic. At the present time we have no standards by which to judge the speed of the street car, except by comparing it with its real competitor—the private automobile.

The ideal characteristic curves of acceleration and retardation for a street car have never been determined, nor has the industry undertaken to find the maximum values which may be considered practical. The rates, no doubt, in the end will be controlled by the ability of the standing passenger load to accommodate itself to rapid movement. This involves not only standing passengers during the rush hour, but also passengers walking from the doors to the seats, or vice versa, while the car is moving. The maximum attainable rates of acceleration and retardation cannot be achieved in any city until the public has been educated to conform to higher rates than now prevail. The present-day public is alert and is quick to adjust itself to new conditions.

Transportation men disagree on the relative merits of speed and frequent headway in attracting riders. Both are important. In this respect, there was much discussion two years ago about the use of smaller units brought about by the development of experimental four-wheel cars. Undoubtedly, the idea of a comparatively small unit, operated on a short headway by one man is fundamentally sound for a great many lines in many cities. Only when traffic densities go up considerably above the average are larger units necessary or justified.

The electric railway man has always been susceptible to the temptation to use large units. It seems such a simple way to reduce the cost per seat, or per passenger carried. But of what good is a reduction in cost, if it is achieved by driving away business? Frequency of service, along with speed, is necessary to increase the volume of riding. But even from the standpoint of speed, small units have an advantage over large cars, for speed is affected by the number of stops. The smaller the total load carried on a single vehicle, the fewer will be the number of stops which it is required to make. Putting this whole matter in another way: the smaller the individual unit that is operated, the closer does the service given approximate that of the individual automobile.

The load factor on the system is all too often overlooked in yielding to the temptation to make sure, when selecting new cars, that they are ample in size. The use of larger equipment in the rush hour is, of course, frequently required, but there are cars now available on most properties for that purpose, and in any replacement program, first consideration should be given to equipment for all-day service. This question of the proper size of cars is an important one in considering rolling stock.

The idea behind the single-truck safety car was sound for a great many lines in many cities, so far as its small size and the implied objective of frequent headway were concerned. But the limitations of the existing types of four-wheel trucks were a serious handicap. The appearance and riding qualities suffered. The car looked too much like what it really was—cheap transportation. It is one of the idiosyncracies of human nature that though

Digitized by Google

we demand economy and an attractive price, we refuse to buy a thing that looks cheap if we can possibly find the money to buy something that looks more luxurious.

Improvement in the proportions, lines and general appearance of street cars to the end that they may be in keeping with their surroundings in modern cities is a second very important objective from the standpoint of the public. Here again the standard of comparison is the automobile. The principal object seems to be to make the street car a more graceful looking and attractive conveyance. The same general objective applies to the interior. There must be proper balance between attractiveness and utility. The design, equipment, fittings and decorations should be in keeping with the purpose for which the vehicle is intended; namely, the mass transportation of passengers in cities.

Only during the past few years have we been giving the question of car appearance serious consideration. In this we have been forced to feel our way slowly, because relatively little attention was formerly given to the appearance of street cars. We are beginning to ask the engineers to fit structural details into a design to produce a given appearance, instead of letting the latter take care of itself after the structural elements are determined.

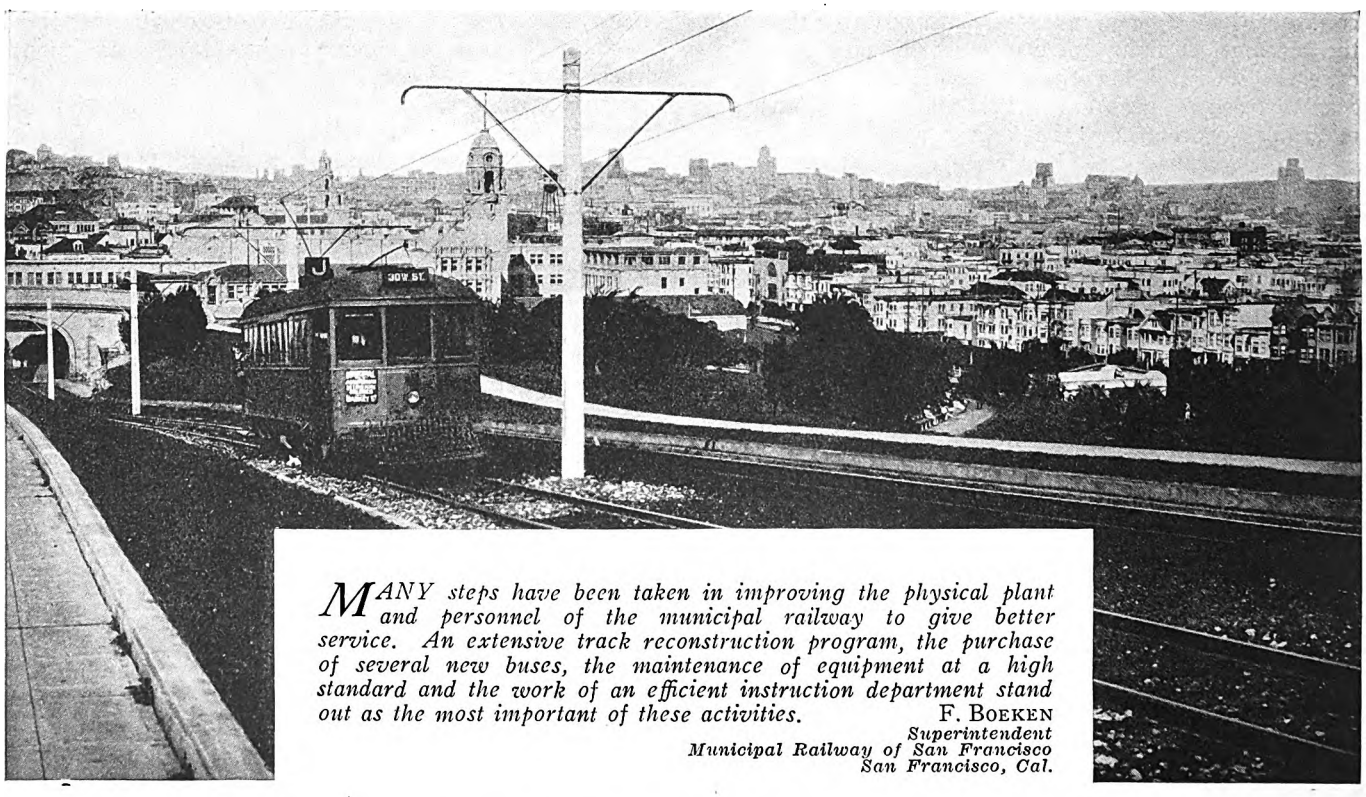
In answer to the steady demand for a smooth and quiet ride, the manufacturers have developed a number of trucks, differing in many respects from the older conventional types. The objectives sought in the designs are reduced weight and noise, faster and smoother starting and stopping with lighter equipment, and reduced unsprung weight. Reduction in unsprung weight is expected not only to improve the riding materially and save wear on the car itself, but also to reduce both noise and wear of expensive special work and tracks. Of almost equal importance is the arrangement of the springs.

Noise has been reduced in some of the newer models by more accurate fitting of gears and other parts, by simplifying the design, and by insulating the springs, brake rigging and other parts from adjoining portions of the structure. The introduction of higher-speed motors made possible by the newer arrangements to support the motors on the truck frame instead of on the axle, has led to the development of several new types of drives. The single-reduction unit, the double-reduction unit and the worm-gear drive are all available for use. The present need seems to be merely the perfection of experimental models and the building up of a record of experience with them that will insure their practicability for the severe conditions of regular service.

From the standpoint of the operator, one of the most important objectives to be attained in car design is a substantial reduction in operating and maintenance costs. Both are largely controlled by the design, age, condition, performance, weight and first cost of the equipment which is operated. The other important operating elements entering into the problem are labor, track maintenance and power. We cannot hope to reduce the cost of labor except as we use labor more efficiently by increasing car-miles per man-hour through improvement in the performance of cars. We have relatively little opportunity of decreasing track costs, except as we are able to reduce wear and tear and maintenance through reduced weight of cars, better suspension design and reduced unsprung weight. Likewise, the largest opportunity for reduction in power cost is afforded by reducing the weight and increasing the efficiency of our cars.

It is imperative that the cost of new cars be brought down to a point where a retirement period of perhaps ten years becomes practicable. Otherwise, with a continuation of the present rate of progress in automobile design, it is probable that new equipment, even of the most modern type that could be expected to be available within a reasonable time, would be entirely obsolete before it could be retired.

A ride through Mission Park over the private right-of-way of the Municipal Railway affords an unusual view of San Francisco



MANY steps have been taken in improving the physical plant and personnel of the municipal railway to give better service. An extensive track reconstruction program, the purchase of several new buses, the maintenance of equipment at a high standard and the work of an efficient instruction department stand out as the most important of these activities.

F. BOEKEN
Superintendent
Municipal Railway of San Francisco
San Francisco, Cal.

Simplicity in line and contour, as well as carefully balanced proportions, reflect efficiency and utility in the new Youngstown cars

Obtaining an

Attractive Appearance

with *Simplicity* and *Utility* in Design

By

R. N. GRAHAM
Manager of Railways
Penn-Ohio System, Youngstown, Ohio

APPEARANCE, external and internal, is a very important feature in the units of modern city transportation. There has been a general tendency in all American cities to devote thought to the impression the city and the component parts of it make upon the individual. Modern buildings are designed with an eye to beauty as well as to mere utility. The urban transportation company can not be alien to the general movement toward improved city appearance.

It has been found that true beauty is harmonious with efficiency and utility. Something added merely for decorative effect we view as "gingerbread" and "Victorian." On the other hand, the harmony in line and contour which reflects efficiency and utility requires studied thought and plan.

The beautiful simplicity of the exterior of a British or Continental locomotive does not in the least interfere with such a locomotive being an efficient piece of machinery. Neither do the long, sweeping lines of perspective of the modern skyscraper interfere with a most economic use of the cubic space contained in it. There has been a tremendous improvement in the appearance of automobiles in the past ten years. This is not the result of adding ornamental appendages but rather is the result of true artistic effort in so designing the proportions of the surfaces of the automobile that the finished product is pleasing to the eye, not only as a result of beautiful proportions but because the finished product so clearly sets forth the power, speed and comfort of the vehicle.

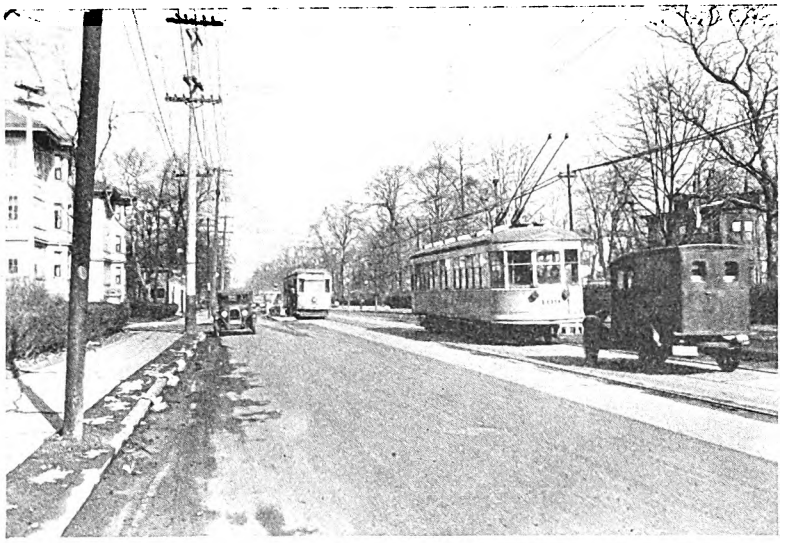
The modern street car should, therefore, be well proportioned with the simplest possible lines. Since an extremely bulky object is out of place on the street, the lines of the street car should tend to diminish and not increase its size. For this reason, the roof should be as low as possible. There is no use for vertical space in the body of the car beyond that which is adequate to take care of standing passengers. The cost of the cubic content produced by greater size than this is wasted. A low car of any dimensions is more attractive on the street, and the saving of unnecessary height produces a saving in direct proportion in the vital matter of weight. Since acceleration and retardation, the chief factors of the modern fast schedule, depend directly upon weight, unnecessary height in a car is not only unsightly but detrimental to the efficiency of the car.



Cincinnati's new cars are in keeping with the tone of the fine residential areas in which they operate

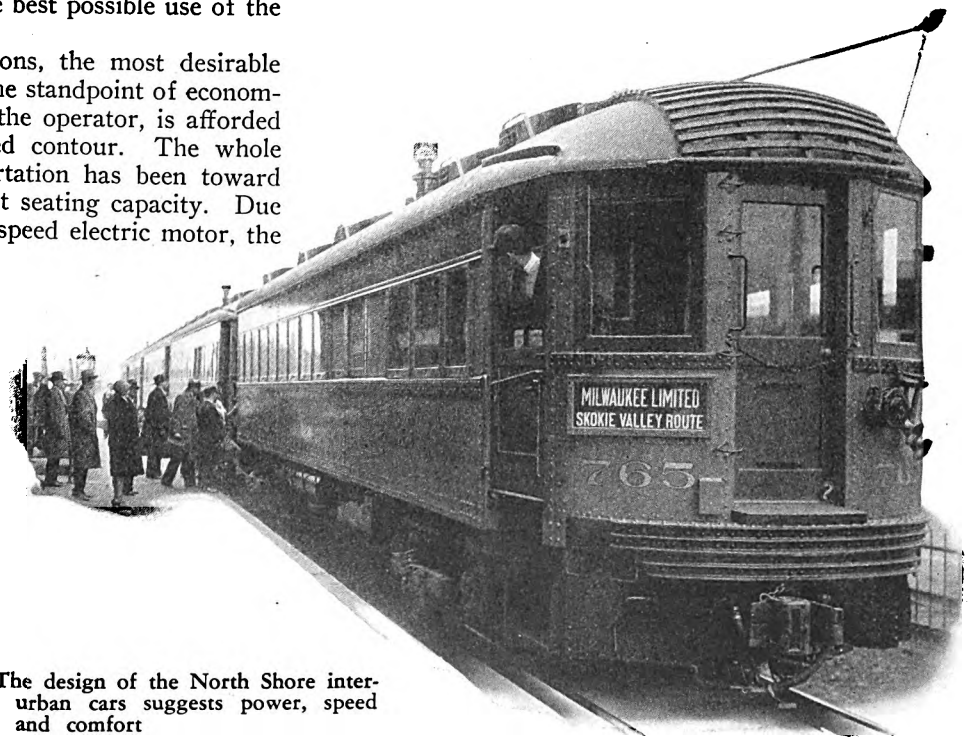
The appearance of bulk in the street car is also minimized through the adoption of single sash. Even though the single sash be as great in vertical dimension as the double sash, it does not accentuate the height of the car as much as the double sash.

Prominent roof construction also emphasizes the bulk of the street car. This construction may result from the roof being too strongly arched, from a monitor deck, from conspicuous ventilators, trolley boards or other appendages. A curved roof with very flat arch and as few added structures as possible makes the most graceful and least bulky roof with the best possible use of the space underneath.

Under modern traffic conditions, the most desirable front end of a street car, from the standpoint of economical use of space and vision of the operator, is afforded by a square and not a rounded contour. The whole tendency in urban bus transportation has been toward the use of buses with the largest seating capacity. Due to the development of the high-speed electric motor, the trolley bus with its high rates of acceleration and retardation has again loomed as an important factor in city transportation. All modern trolley buses have been designed with square ends approximating those of the large capacity urban bus. The street car with a square front end thus will harmonize in appearance with the trolley bus and the gasoline bus, permitting all the essential elements of the modern transportation utility to be harmonious in appearance.

Street cars have been placed in operation in many cities within the last year or two which have shown the appreciation by the designer of the benefit of careful proportion and construction of external elements of the car which reflect credit on the progress that is being made in this important matter.

In choosing the color scheme of the urban transportation system, consideration should again be given to the general effect created on the street. In a city of any size the units of the transportation company, be they street car, bus, or trolley bus, comprise a large part of the picture presented on the street. An essential factor of this effect is color. Color, in looking merely at the street car itself, is one thing; the color of the street cars on the street, when taken along with everything else in the view on the street, is quite another matter. I am firmly of the opinion that orange, which in the past has been a favorite street car color, does not fit in well with the general scheme of things on a city street. It is necessary, from the standpoint of safe operation and the prevention of accidents, that visibility be considered in adopting a standard color. There are a variety of tans, greens, browns, creams and similar colors that can be adopted to produce not only visibility but a pleasing and harmonious appearance. But, whatever colors may be adopted, they should be used to produce an effect of simplicity. If two colors are used, one should be placed



The design of the North Shore interurban cars suggests power, speed and comfort

Digitized by Google

below the base of the windows and the other above that line; if three colors are used, one below the base of the windows, the second from that point to the roof and the third on the roof. Complicated striping, large ornamental designs, sunbursts and dragons are entirely out of place on a transportation vehicle.

Whatever color is adopted, it must be kept up as a color. Any mercantile establishment in a modern city that looks decrepit and run-down is going to pass out of the picture. A street car or bus that has been painted a distinctive color that has been allowed to deteriorate and become old and patchy is an offense to every one in the city that sees it, whether or not it is realized. The use of modern lacquers makes it possible to restore the color of the transportation unit comparatively cheaply. In no respect can a transportation company make good its boast of furnishing a real service to better effect than by insistence upon keeping up the color of its vehicles.

The most economical floor for a street car is wood. However, there are other floor coverings that have a great deal more passenger appeal that possess no element of frill or "gingerbread" and the use of which is dictated by ordinary business instinct. The three alternatives in most general use are linoleum, rubber and flexolith, or similar mineral preparations.

Linoleum, particularly battleship linoleum in a solid color, presents a pleasing appearance but is more or less subject to wear. Rubber floors are not satisfactory on city cars because of the inability to keep them smooth and level under the conditions of city transportation. Flexolith flooring seems to have no serious defects. While it costs more to install than the ordinary wood floor, it presents a pleasing appearance, is not slippery and has splendid wearing qualities.

Any city transportation unit should be well lighted. The tendency in modern life is to be content with no middle ground in illumination. A street car should be so well lighted that passengers can easily read and so that the cars present a brilliant appearance on the street.

The lights in the car should be carefully placed to insure the best possible diffusion and the highest degree of comfort to the passengers. The latter consideration dictates that there should be two rows of lights from the front end of the car to the rear end, one over each row of seats. The modern dome fixture presents a most pleasing appearance, creates the best diffusion of light, permits lower headroom in the car and is easily cleaned.

Another modern development in street car design is the paneling-in of the air pipes to the air valve, controller and switches. It is another praiseworthy development which has no essential drawback. Of course, in inspecting such apparatus it may be necessary to remove certain panels, and in case of a collision involving the vestibule it may be necessary to replace these panels, but these are comparatively minor factors compared to the positive improvement in appearance. Simplicity should be the outstanding feature of the transportation unit and this simplicity of appearance can not be gained if a miscellaneous collection of pipes, switches and other apparatus clutters up one or both ends of the car.

The tendency in the modern car is to insist upon having headlining. Of course, it should be as light in weight as possible and should be perfectly smooth and painted in a light color to conserve the illumination of the car.

The whole tendency in modern design is to have cross seats the full length of the car. Since a handhold is provided on the corner of every seat, there is no real necessity in the average city of hanging straps. These straps are unsightly, are associated with the cry of "strap-hanger," the relic of an older and unhappier day, and are wholly unnecessary. Stanchions should be as few as possible and should be of non-corroding material.

With large sash, composition floor, comfortable leather seats, smooth headlining, dome lights furnishing brilliant illumination, all machinery concealed, no straps and few stanchions, the interior of the modern street car is an attractive place and it has the true beauty of simplicity and efficiency. It would be less attractive if there were Turkish rugs running down the floor and costly hangings were at the windows, because it has that beauty which comes from adaptation to its purpose; nothing cheap and nothing gaudy. The exterior, too, should express the same ideal.

WELL-MAINTAINED equipment, reliable operating schedules and the general appreciation of business, reflected in our attitude toward the public, have enabled the Napa Valley to retain the maximum patronage and general public good-will, not only essential but necessary to continued operation. Although we have suffered from the competition of the private automobile we have been able to compensate some of the loss in passenger business by increased revenues from other service developed, principally mail, express, freight and motor bus.

THERE is no doubt that the development of better mass transportation vehicles, both rail cars and motor coaches, is one of the most vital problems in the industry at the present time. Improvement must be made toward faster speed, greater comfort and convenience, longer life, lower maintenance, better appearance and greater appeal to the public we serve.

In spite of many handicaps the mass transportation systems continue to be the backbone of the community, the circulatory system of business and the chief factor in the making and stabilizing of property and business values. Yet the public at large does not understand our most obvious problems and their vital relations to the progress of the community. It is our own job to change this situation. Scientific and sustained effort to improve our equipment will be a very important step in this direction.

Latest type of car designed for speedy operation on heavy traffic routes in Brooklyn

SPEED —*an Essential of* Street Car Performance

By

W. T. ROSSELL
Vice-President and General Manager
Brooklyn & Queens Transit Corporation
Brooklyn, N. Y.

IT IS difficult for the old and impossible for the young really to comprehend the progress of urban transportation. Within the span of 30 years, the horse-drawn and the "horseless" carriages have evolved into the modern automobile, the hack into the taxicab, the carry-all into the motor coach, the wagon and the dray into the motor truck. At the turn of the century vehicular speed was ordinarily limited to 8 m.p.h. A horse, traveling at 15 m.p.h. was a runaway, causing great excitement. Into this bucolic scene of 30 years ago came the modern electric street railway car, startling in its beauty of line, its power and speed, controlled by powerful air brakes. This product of inventive genius and pioneering courage took its place as the unchallenged leader of urban street traffic.

Where are the vehicles of that day? It is as though they had never been. Innumerable models have come and gone. The streets are filled with the rush of automobiles. They seem commonplace now with their streamline bodies, their power and speed, their four-wheel brakes and easy, accurate steering. We accept as natural speeds of 30, 40, even 50 m.p.h. And yet, today, may be seen in many places the identical electric street railway car of 30 years ago moving through the streets. The car is the same, but all else is changed.

To bridge this gap is the problem. Public acceptance of the automobile clearly points the way. Limited by function, street car performance must approximate that

Digitized by Google

of the automobile. The street car must be made capable of holding its own in traffic. This means more speed, and the bare essentials involved in making greater speed practicable can be classified under the subjects of braking, acceleration, running speed of motors, weight, and rate of handling passengers.

There are natural differences of opinion as to the relative importance of these items. In the following discussion, where figures are given, they are not meant to be arbitrary or final, but merely indicative of opinion.

Safety is presumed to be included in the sum total.

One of the most important steps in automotive design and one which has added greatly to the average speed of traffic is the development and application of the four-wheel brakes. Many street cars have an average braking rate no greater than 1½ m.p.h.p.s. This accounts for much of the slow, hesitant op-

eration, so common to street cars. It is not even as efficient as a one-wheel brake on a rubber-tired vehicle would be. Rates up to 5 m.p.h.p.s. on street cars are possible without a rail brake. The latter would probably be necessary for emergency use and to give the needed assurance. Rates of braking should be variable and selective at the will of the operator. Much progress has been made in this matter, but there remains opportunity for still further improvement.

The power plants now in use in automotive equipment are significant. The "get-away" is the important element in taking advantage of the "breaks." Rates of acceleration should be variable and selective at the will of the operator with a maximum up to 5 m.p.h.p.s. A rapid rate of acceleration should be continued into relatively high running speed.

It is imperative that the passengers be handled gently. Sudden changes in velocity create an accident hazard, make the ride uncomfortable, and discourage the passenger from leaving his seat before the car stops. It should be understood that it is not the high average rate of braking or acceleration that causes these evils, but the momentary sharp changes in rate. Specifically, the rate of change of braking and acceleration must be kept within limits to be determined experimentally.

All cities have large areas where vehicles are run at high speeds. Here automotive performance points the way. The same vehicle must have sufficient flexibility to operate satisfactorily in either congested or in free running areas. Whether obtained through series winding, tapped fields, variable line voltage or other means, the ideal is that the free running speed be variable and selective to suit the conditions. A maximum of about 40 m.p.h. is suitable, giving rapid operation uphill and first rate suburban service. A minimum of about 30 m.p.h. is suitable for congested areas. These figures approximate average automotive performance. They may be used as guides and compromised to the extent made necessary by limitations in electrical equipment design.

The control of weight permits higher average speed by keeping power costs within reason. Weight of a 45-ft. car should not exceed 30,000 lb., and should be brought nearer to 25,000 lb. through skillful design and careful selection of materials.

The rate of handling passengers has been given careful study and great strides have been made in improving equipment and method. Besides the training of the operator, many other things also are involved, such as steps and ramps, floor height, door and aisle widths, fare collection devices, heating arrangement, stanchions, hand holds, etc. Specialization of bodily functions of the one-man car operator is an important advantage obtained by foot control.

More and more, the subject of speed is claiming the attention of electric railway operators. Recent improvements in design have done much to increase operating speeds, but the goal has by no means been reached. Every fraction of a second regularly saved per stop is worthy of effort.

FREQUENT improvements in the cars to increase their attractiveness and changes in the track to increase the riding qualities have enabled the East Bay Electric Division, which operates 780 trains daily and about 4,000,000 car-miles annually, to render the highest character of service to its many patrons.

The extensive trolley bus system recently inaugurated in Chicago serves a well-developed section of the city

The Improved Trolley Bus

Makes a Bid for

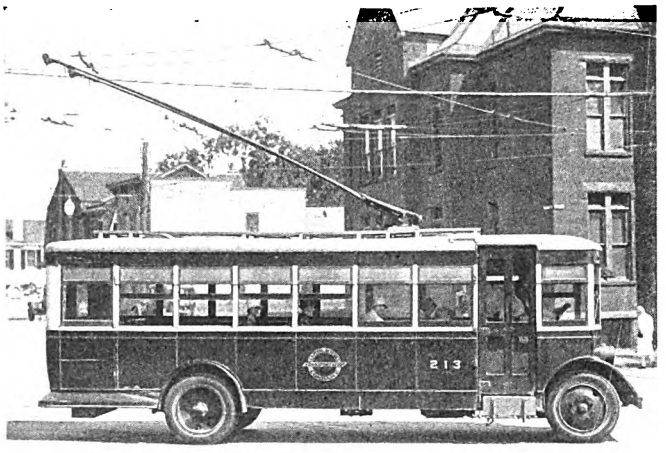
POPULARITY

RADICAL changes in the design of the trolley bus, incorporating the best features of both the street car and the gasoline bus and eliminating the faulty characteristics of the earlier vehicles, have definitely brought back this vehicle as a type of transportation worthy of consideration for many kinds of service. Although the first trackless trolley appeared in Germany in 1899 and the first one in this country in 1902, comparatively little progress was made in its development until recently. The earlier types were not satisfactory and as a result the vehicle was not adopted to any great extent. However, the adoption of the light-weight, high-speed motors developed for street railway operation, the use of pneumatic tires, the creation of excellent riding quality, and the building of a large capacity light-weight bus body, equipped for circulating loads, overcame the earlier defects and resulted in a design which has proved to be very satisfactory.

First recognition of the newer models of trolley buses came with the installation of ten vehicles in Salt Lake City in September, 1928, and of eight in Manila, P. I., about the same time. In November, 1929, New Orleans placed two in operation, and in April of this year Knoxville inaugurated a system using four. The largest system in the country was inaugurated in Chicago recently, when a total of 55 vehicles was ordered to serve more than 35.5 miles of route in the northwest part of the city. Detroit is just beginning to operate trolley buses and other cities are seriously considering the installation of this type of vehicle. It appears that it is definitely beyond the experimental stage and well advanced toward widespread adoption.

Analyses of the characteristics of this type of vehicle, its first cost and maintenance expense, its advantages and disadvantages, its performance and the public response seem to indicate that it has a very definite usefulness. Because of varying conditions in different cities and on different routes within one city no definite rule can be stated covering the use of the trolley bus, but general statements can indicate the possibilities.

Digitized by Google



The type of trolley bus developed for the Capitol District Transportation Company for its Cohoes line in 1924, represented a big advance over previous designs

Briefly summarized, its advantages with respect to the street car are its complete absence of noise and its ability to load and unload at the curb. Among its disadvantages it is to be noted that the smallness of the unit and the difficulty in getting adequate widths of aisle and lengths of platform, make it somewhat slower and more inconvenient for loading and unloading with a large interchange of passengers. Because it is a steered vehicle it operates as do all such large units, in a way that requires more clearance space on a street than a street car, and in weaving from the curb lane out toward the center of the street and back it creates more traffic interference than does a street car on fixed rails with safety zones at the loading points. The rocking of the bus due to the irregularity of the pavement, and the swinging of the unit due to the steering, cause greater inconvenience to standing passengers or those walking to or from the doors than the relatively smoother movement of the street car on good track, provided the street car is one of equally modernized design.

The trolley bus is greatly superior to the gasoline driven bus in that it has more rapid and smoother acceleration, can develop higher schedule speeds on lines with frequent stops, has complete absence of noise, and eliminates entirely the unpleasantness and danger from exhaust fumes. Because of its unlimited supply of power from the trolley wires it has opportunity for better heating, lighting and ventilating. It uses a more effective source of power at a much lower cost per car-hour. The trolley bus can be maintained by the existing shop force trained for street car maintenance, and it does not involve serious fire risk. Because the trolley bus may be treated as a street car in limiting the routes over which it may travel, it is quite likely to obtain permission in all states to build the bus at least 6 in. wider than is permitted for gas buses which are likely to operate at times even on state highways outside of cities. This additional width used for the aisle makes a tremendous improvement in convenience for the passenger. If this width can be obtained it will make an asset out of the use of fixed poles and wires.

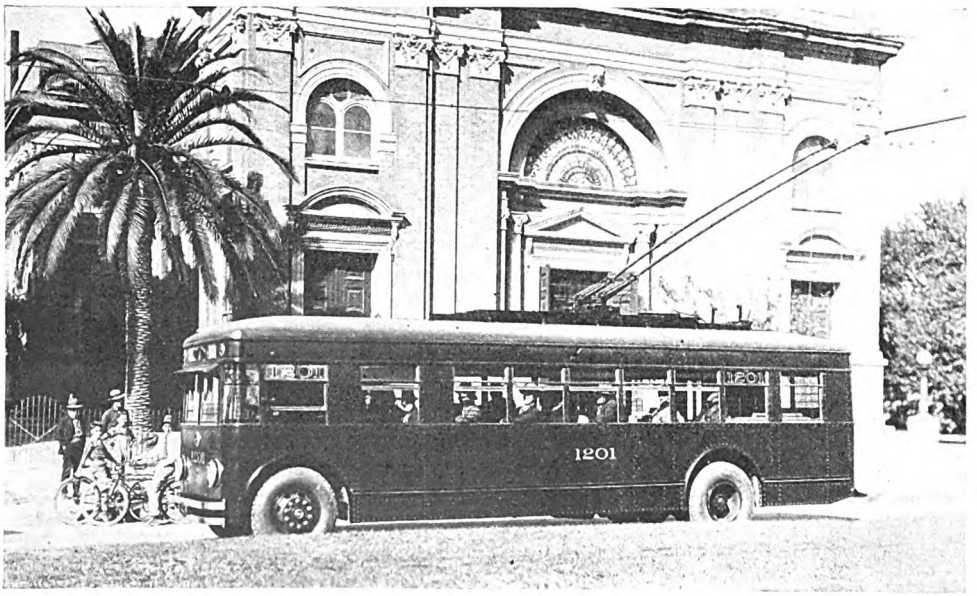
Operating Cost Low

The relative costs of operation are much in favor of the trolley bus in spite of the interest on the investment in overhead structure and the maintenance costs of that structure. It is a very slim service indeed that will not justify the additional expense in poles and wire, providing the service is likely to be continued. Naturally, if the investment in trolley structure is already made for street car service, the cost of the changes would be still more easily supported.

In analyzing these differences one arrives at the conclusion that the trolley bus is best suited for service on routes which do not yet have sufficient traffic to warrant street car operation. From an investment standpoint it is more attractive than the street car on such streets because of the lower first cost and because no permanent way is needed. From an operation standpoint the trolley bus is superior to the motor bus because of its ability to maintain a higher schedule speed with maximum comfort to the passenger and at a lower cost.

Because the trolley bus requires only the installation of overhead wires the investment is small enough to be justified when the patronage of the line is limited. With an appropriate increase in traffic, street car operation can be substituted for trolley buses by laying tracks. Thus, the trolley bus serves better than the bus in developing new areas and in serving as an extension for electric railway lines.

In some places trolley buses have been substituted for street cars on routes where the track was in need of complete reconstruction and where the travel was not sufficiently heavy to warrant this additional expenditure. Other installations will doubtless be made for the same

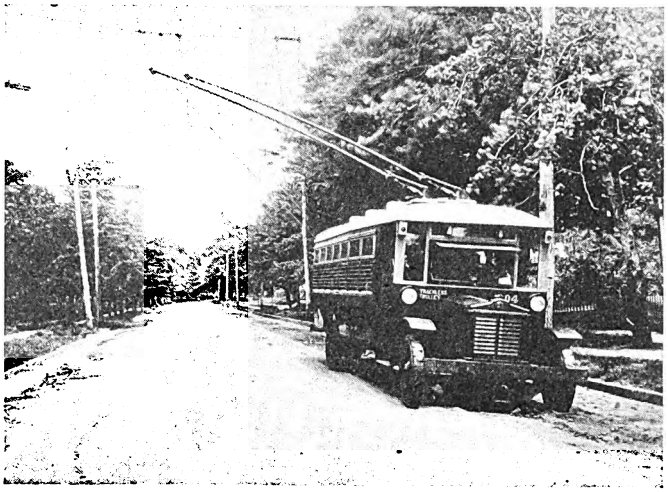


Trolley buses were substituted for street cars on an outlying shuttle line in New Orleans late in 1929

Digitized by Google

reason. On car lines where traffic has decreased to a considerable extent the substitution of trolley buses may be an economical and satisfactory move. Such a change usually substitutes the new buses for rather old street cars of a less desirable type, and is quite likely to encourage much new riding.

In middle-size and small-size cities, the trolley bus may prove the salvation of many electric railways. In general, patronage is falling off in the smaller cities, due to the competition of the private automobile. Rehabilitation of the track and rolling stock in these communities would no doubt help them in regaining lost patronage and securing new, but few of the railways are financially in a position to undertake such a program. The substitution of trolley buses would seem to be a logical step in the majority of these instances, because the vehicle would be able to give long service, would preserve a large part of the investment, would offer a service comparable to that given by the private automobile and would retain a permanent form of transportation for the community.



The old trackless trolley, with truck chassis, high body, projecting hood, heavy railway motors and hard rubber tires

Co-ordination of Three Types of Service

Depending on the size of the city and the number of prospective patrons along any given route, the trolley bus will find varying possibilities as substitution for or co-ordination with street cars and buses. It is quite probable that, as experience with the trolley bus increases and its economic field is more clearly established, the three types of units will be found in operation in American cities all fully co-ordinated.

Although the street car has been improved materially in the past decade, it still lacks a number of the more important characteristics demanded by the automotive minded public of today. Some of these characteristics are possessed by the trolley bus. The great improvements just now being made in street car design will tremendously improve the desirability of the coming street car over anything yet in use, and will retain for the street car a position of good standing as a public carrier unit.

Fundamentally, there is a definite field of usefulness for each of the three types of vehicles. The street car, as improved in the very near future, will retain its position in first place as the right vehicle for public transportation service on heavy traffic lines, except where rapid transit is necessary. The trolley bus can well be adapted for extensions, for some residential streets of a boulevard type, for lines which are too light for the street car and for other supplementary service in co-ordination with the street car or rapid transit. The bus will no doubt continue to prove the best vehicle for extensions into very light traffic areas of uncertain future, for temporary supplements to the permanent forms of transportation, for special express type service or for service along some boulevards and in such parks where the advantage of the trolley bus in giving relief from gases and an excess of noise may be outweighted by the undesirability of having an overhead system with poles and wires.

Many factors influence the choice of type of service, and differing weight may be given to the various factors under varying conditions. Modernizing the street car is being undertaken in a very aggressive way, and its material advantage in large cities or in heavy service will remain. The value of the trolley bus will be widely recognized, and to many cities it will prove of tremendous value in restoring public confidence and interest in the public carrier as well as in providing an earning power to the operating company. It is not an equipment that can serve to replace the street car on the important routes. But it is an excellent new development of which the railway organizations should avail themselves for much supplementary service.

This sample car in Detroit embodies practically all of the latest noise reduction features—light weight, reduced unsprung weight, insulated floor, worm gearing, insulated trolley base and special air compressor mounting

Lowering Costs and *Bettering Public Relations* by REDUCING NOISE

By

H. S. WILLIAMS

Assistant Superintendent of Equipment
Department of Street Railways
Detroit, Mich.

IS NOISE reduction worth while, or is it merely something which would be nice although not of sufficient importance to justify the effort needed to obtain it? We have demonstrated in actual practice that cars can be made much quieter than they are. We know that this is a vital thing and it can be proved that it is the practical thing to do.

Quite naturally one of the first considerations is the cost. With railways striving to make every dollar yield its utmost in value, this aspect of the case must be of prime importance. It is fair to assume that if it can be proved that noise reduction can be accomplished with a saving in maintenance expense it will be adopted, for economic practice is the only one which will survive.

Common sources of noise in a street car are loose parts. These parts vibrate or by rebounding set up vibrations which are interpreted as noise. For example, take the motor axle bearing. When this is new its movement in the vertical plane is so nearly zero as to be negligible. When wear sets in, the movement is increased and heavy hammer blows are delivered, which mean noise. In the initial stages of service a wear of 0.001 in. means a life of approximately 5,000 miles, but when the bearing has worn so that the clearance between axle and axle bearing is $\frac{1}{16}$ in., a wear of 0.001 in. meaus a life of only 500 miles. It is at this state that it becomes a noise producer of consequence.

Let us now examine the economics of this case. The bearing is worth approximately $6 installed. It has produced, up to the time represented by the $\frac{1}{16}$-in. wear, a mileage of 69,000. If the bearing is allowed to run to double this wear, the total mileage amounts to but 77,000 or an increase of only 8,000 miles. (See ELECTRIC

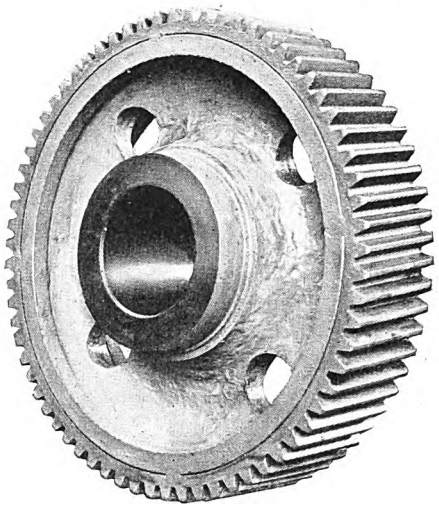
Cross-section of Timken-Detroit Axle Company worm-gear driving unit. This type of gearing effectively eliminates noise



Quiet gear of the Westinghouse Company, using a wrought-iron band welded at several points to the gear rim

RAILWAY JOURNAL, issue of Feb. 19, 1927, p. 347.)

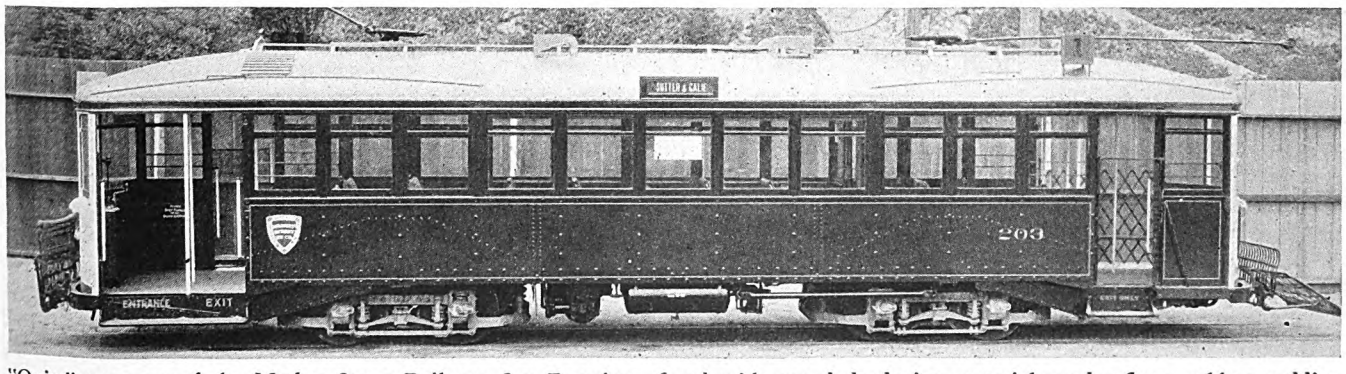
If the bearing be removed at the end of $\frac{1}{16}$-in. wear, the cost per 1,000 car-miles will be 8.7 cents, while if allowed to run to a wear of $\frac{1}{8}$-in. the cost per 1,000 car-miles will be 7.8 cents and the net saving will amount to 70 cents. To secure this saving, it is necessary to consume an excess amount of energy amounting to approximately $6.55. This figure represents the frictional loss in the bearing during the added 8,000 miles which is equal to the loss occurring during the previous 69,000 miles. Summarizing this phase of the problem, it has cost $6.55 to save 70 cents.

This only the direct saving by taking the proverbial stitch in time. In addition to this is added gear wear caused by allowing abnormal separation of gear centers. This in turn lowers the efficiency of the gears. The gear loss from a set of spur gears when new and operating under the best of conditions is approximately 2 per cent. If we allow an added loss of 0.1 per cent for the spread centers, a conservative estimate, then with an 18-ton car in ordinary city service an added energy loss of approximately 45 cents per bearing is entailed. This amount should be added to the $6.55 previously mentioned.

In addition to this is added gear wear greater than the normal wear. It is difficult to evaluate this factor, but it is present and a very definite thing nevertheless. Moreover there is the intangible nuisance of noise which has been added to the sum total of other noise of the car. In an age like the present where everyone is becoming noise-conscious there can be no question that noise suppression has a value even though it is impossible to reduce it to dollars and cents as concerns its reaction upon our patrons.

To sum up the above case, the bearing which has been allowed to run its limit of wear instead of being changed when it should have been, has given an increased mileage of 8,000, or 11.6 per cent, and represents a saving of 70 cents. But to secure this saving it has cost $7 plus added gear wear, plus the annoyance of noise. So in reality there has been an economic loss of $6.30 per bearing in addition to the intangibles mentioned. Such a thing is indefensible.

We have taken this case of delayed maintenance because we have definite data concerning it upon which to build a case and which we can prove to be true. Other

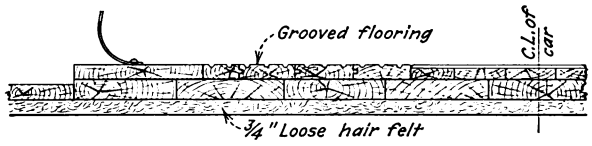


"Quiet" type car of the Market Street Railway, San Francisco, fitted with sound deadening materials under floor, rubber padding between car bolster and frame, leaded master gears, insulated gear boxes and quieted air compressors

Digitized by Google

wearing parts of the car are in the same category and wear proceeds in a similar fashion in them. Delayed maintenance and its consequent noise is much more expensive than maintenance applied at the proper time. Perhaps it might be better to say that reconditioning of parts in the early stages of wear is true maintenance, while letting wear run to the limit is nothing but repair. True maintenance is something that is orderly, scientific and economical; repair is a slipshod makeshift and very expensive.

Having shown that noise reduction means cost reduction from the maintenance standpoint, let us now look into some of the features which should be built into cars to make them inherently quieter. One of the points of greatest importance under this heading is weight reduction, especially the reduction of unsprung weight. Much thought has been devoted to this idea and a great deal has been accomplished in a developmental way. To be sure, the great objective has been reduced operating cost but the noise-reduction value of the lighter weight should



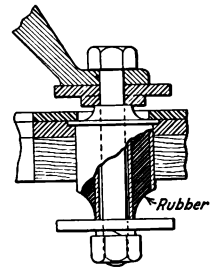
Floor design of the Detroit Department of Street Railways using a ¾-in. layer of loose hair to absorb sound

not be overlooked. To give an idea of this expressed in percentage it may be stated that if the weight of a car be decreased 10 per cent, the noise due to wheel impact will be reduced 3.64 per cent; if the weight be reduced 20 per cent the noise will be lessened by 7.72 per cent. Inasmuch as noise due to wheel and rail contact is one of the major sources of annoyance, the reduction of weight is very important.

Gearing is another important source of noise. Spur gears with large teeth which have been standard up to the present time are prolific noise generators even when new and, of course, to a greater degree after wear has set in. The remedy for this on present equipment is to muffle the gear case which acts as a sounding board. This has been done effectively by the Chillingworth Company which has perfected a padding for this purpose. The Westinghouse-Nuttall gears have the ringing deadened by means of a wrought-iron band welded at several points to the inner side of the gear rim. A lead-filled groove is used by the Tool Steel Gear & Pinion Company for damping the ringing of gears. Were it not for imperfections in the gear teeth resulting from heat treatment, there would be greatly lessened demand for means to stop gear noise. Another efficient method of elimination of gear noise is to use worm gearing, a typical example of which is shown in an accompanying illustration.

As the greatest proportion of car noise originates beneath the car floor, the comfort of passengers will be greatly helped by the use of sound absorption material under the floor. There are two methods of doing this which have been tried out in actual service and which have proved satisfactory. The plans developed by the Market Street Railway of San Francisco and the Department of Street Railways, Detroit, are shown in accompanying drawings. The latter scheme by actual measurements shows a reduction of noise as heard by the passenger of 8.9 per cent.

The side sheathing of car bodies may be effectively



Method of mounting trolley base to eliminate noise. Rubber is used in tension rather than in compression

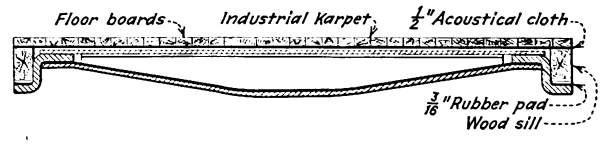
sound-proofed by a method similar to that used for flooring in Detroit, but in this case the material should be cemented to the steel panels.

Trolley-wheel noise is annoying. It may be conquered, however, by the employment of a trolley base mounting as illustrated. Tests have shown this to be so effective in city service that no sound could be heard except when the wheel passed an overhead frog or crossing. The vital point in this mounting is that the rubber is used in tension. Rubber when used as a vibration insulator is much more effective when it is in tension than when in compression. The noise of air compressors, too, may be minimized by the use of mountings similar in nature to those employed for trolley bases.

Often in fitting new pinions to worn gears, both in the case of car propulsion motors and air compressor motors, the profile of the new pinion does not properly match that of the used gear. Recently we have used a new lapping compound to run in the pinions with success.

The points previously discussed are a few of the major points having to do with the car equipment. What of the track? That, too, has a most important bearing upon car noise. Rail, in order to contribute its share to the reduction of noise, must be smooth; it must be free from corrugation and loose or cupped joints. It should have flange bearing crossovers. It must have a measure of resilience so that sound vibrations will be absorbed or damped. A soft and rough surfaced paving will be quieter than a hard smooth surface. The modern monolithic type of track construction in which concrete pavement is integral with the track ballast is a serious offender to the noise sensitive public.

Car noise is not merely a nerve irritant. It bears a



Industrial Karpet, acoustical cloth and rubber padding are used by the Market Street Railway for floor insulation

direct relation to cost in a different way than has been pointed out previously. Noise in many instances is an indication of something wrong—that reconditioning has been too long deferred. But noise is basically a vibration of parts and that in turn is an indication that metal parts are being subjected to millions of successive stresses. This in turn leads to fatigue of the metal and failure of parts. Consequently whatever may be done to reduce noise has a beneficial bearing upon the life of equipment

The subject of noise reduction is being given much study by different bodies. The electric railways and automotive concerns are interested in it to make their transportation vehicles more popular. The National Safety Council is studying it to determine its effect upon the nervous systems of workers. Civic bodies are taking up the question and demanding the suppression of noise. To summarize then, noise reduction is necessary from the eocnomical standpoint, from the humanitarian view and because of bettered public relations.

Meeting the Passengers' Demand for

GREATER COMFORT *and* CONVENIENCE

By

H. A. OTIS

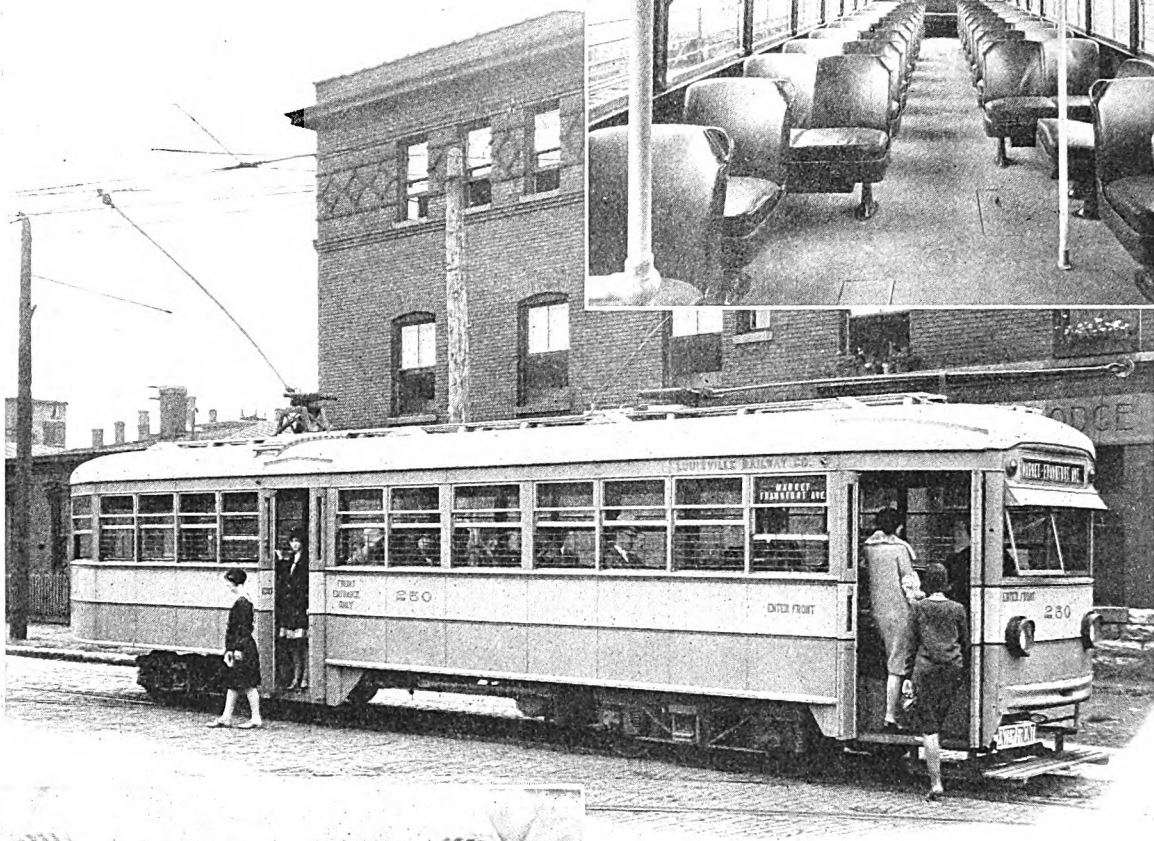
Engineer Car Equipment
Chicago Rapid Transit Company
Chicago, Ill.

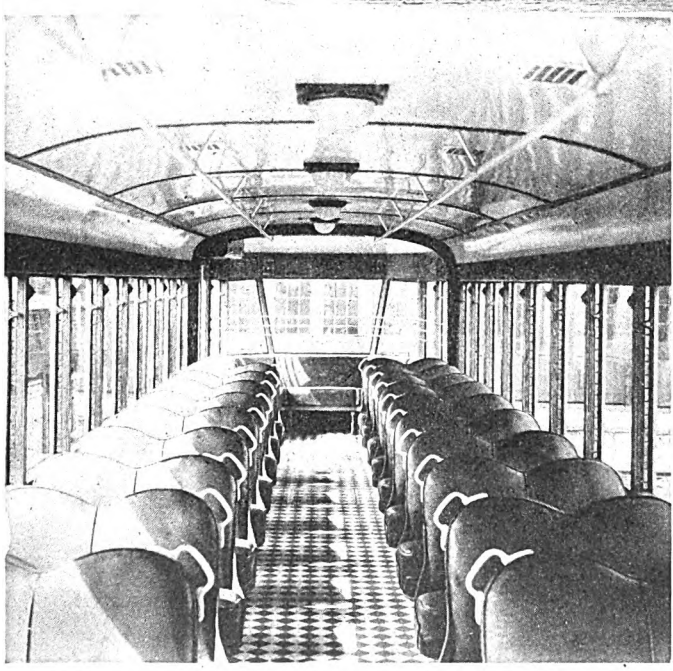
LONG STRIDES have been made in the last few years to provide greater comfort and convenience for passengers in the design, arrangement and equipment of electric railway cars. Heating, ventilation, lighting, seat design and trucks all have been improved to an encouraging extent in the general move of the industry to attract more patrons. Equipment engineers have made much progress, but are continuing to work on this big problem of the railways. They realize that many more changes in design must be effected to make the service even more attractive, comfortable and convenient to the rider, and more economical for the operator.

When the electric railway properties were first built, they filled a great need and were an indispensable part of the community in which they operated, being practically the only satisfactory means of local transportation. The city car made it possible for people to move out and live in less congested areas. The interurban, with its frequent headway and moderate speed, made it possible for people to go from town to town or farm to town in a short interval of time. In those days they performed a service far superior to any that existed and enjoyed a good patronage.

Digitized by Google

Many features to increase comfort and convenience are incorporated in the designs of the three Louisville sample cars





Top view—Two rows of dome lights, a reflecting ceiling and wide windows give ample artificial and natural light

In center—Automatic acceleration allows a high rate of starting without disturbing passengers

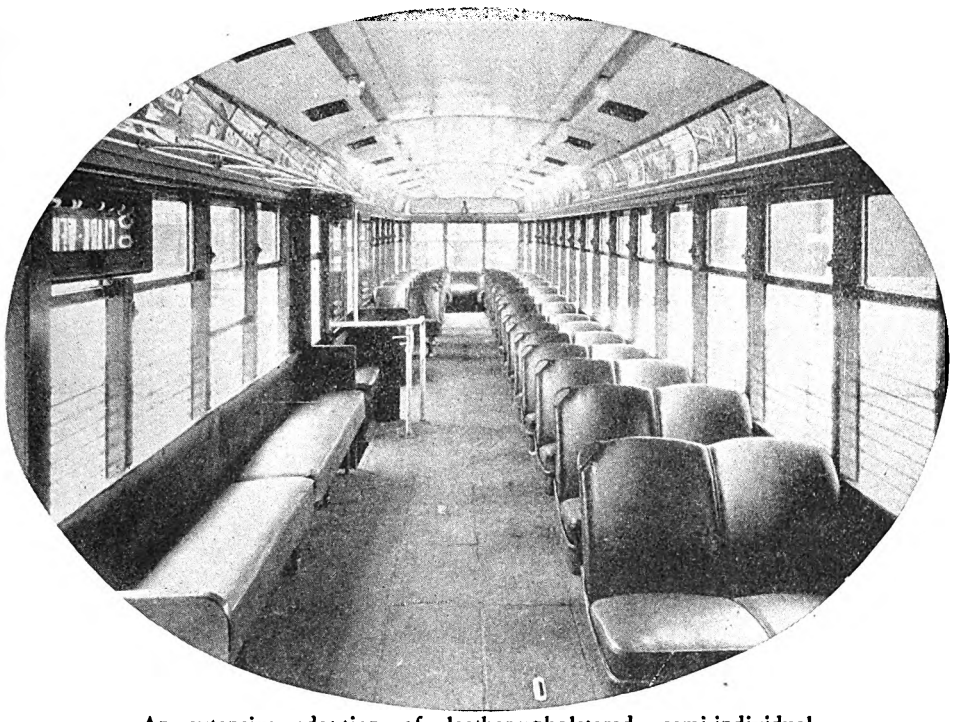
Bottom view—For the convenience of standees a wide aisle, projecting grab handles on the seats and horizontal stanchions are provided

The general introduction of the automobile, the bus and improved roads, however, brought very keen competition to the electric railway. Street and interurban cars of the old type lost their appeal to the public and many passengers adopted a newer form of transportation. The private automobile set a new and higher standard and the public rapidly showed their preference for vehicles with greater appeal. With these facts in mind the car equipment designers were faced with the problem of developing cars comparable or superior to the private vehicle. Their efforts to solve this problem have resulted in the development of many new cars, several including radical departures, and all showing a vast improvement in appearance and comfort over the older type. In the following paragraphs are listed many of the changes that have been incorporated in car design.

Heating—A new type of electric heater has been developed in which the heating element is entirely inclosed in a protecting steel sheath. This arrangement reduces the possibility of fire and electric flash which may occur when the open type element breaks with current on. A larger number of heaters have been installed on the newer type cars, many with full thermostatic control, thus giving a better distribution of the heat and a uniform regulation.

Many of the older interurban cars are heated with coal burning, hot water heaters with iron radiating

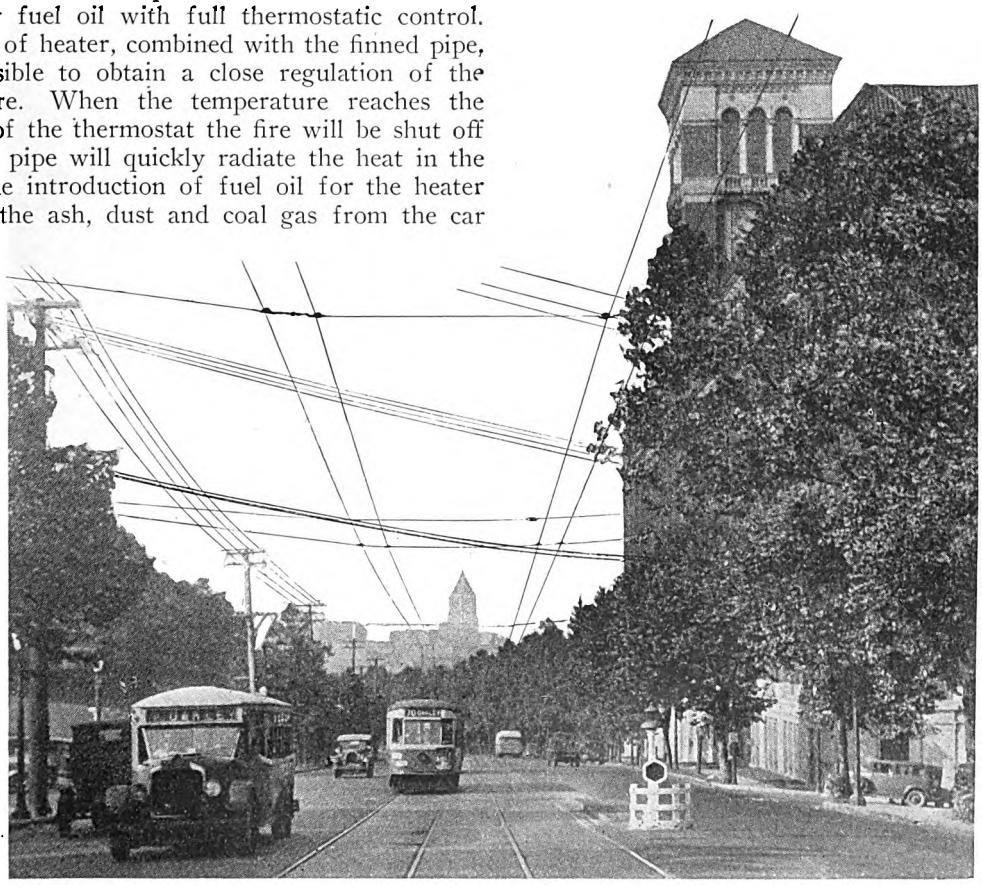
Digitized by Google



An extensive adoption of leather-upholstered, semi-individual cross seats for heavy city service was made in Chicago's 100 new cars

pipes along the sides of the car. The radiation of the heat has been greatly improved by the recent introduction of finned pipe. This finned pipe consists of ordinary iron pipe or steel tubing to which are attached vertical steel plates, thus greatly increasing the radiating surface. The biggest objection to the hot water type of heating cars has been its difficult regulation. Tests are being conducted at the present time on a hot water heater burning fuel oil with full thermostatic control. With this type of heater, combined with the finned pipe, it will be possible to obtain a close regulation of the car temperature. When the temperature reaches the upper setting of the thermostat the fire will be shut off and the finned pipe will quickly radiate the heat in the hot water. The introduction of fuel oil for the heater will eliminate the ash, dust and coal gas from the car interior and the necessity of having additional men during the winter months to tend the heaters.

Ventilation—The old deck sash type of ventilation has been replaced with automatic exhaust ventilators and in some cases with automatic intake ventilators. Tests are being conducted at the present time with forced ventilation. One system consists of a number of fans installed in ventilators in the roof; another



Many comfort and convenience features are found in the latest cars and buses of the Cincinnati Street Railway

Digitized by Google

consists of a large exhaust fan mounted under the floor, connected to registers in the floor by means of a duct. With the automatic type of ventilator the amount of air exhausted depends principally upon the speed of the car and the direction and velocity of the wind. With the forced exhaust ventilation the amount of air exhausted is entirely independent of the external atmospheric conditions.

Seats—A great improvement has been made in car seats. The older type of cars were equipped with uncomfortable longitudinal or cross seats, some made of solid wood, others upholstered with carpet or hard rattan. The new cars are equipped with the greatest number of cross seats possible, and the design of these has been changed so that they are much more comfortable. The seats in these newer cars are upholstered with plush, leather or a good grade of imitation leather. The seat spacing also has been increased to allow more room for the knees of the passengers.

Lighting—The older type of cars were equipped with bare light bulbs and no fixtures. Lamps were of insufficient candle power and so few in number that there were only one or two foot candles at the reading plane. The new type cars are equipped with light fixtures, many of the dome type, and a sufficient number of high candle power lamps to give five or six foot candles at the reading plane. Too much emphasis cannot be placed on the necessity of good illumination, as a well illuminated car greatly adds to the convenience of the passenger and to the attractiveness of the car from the outside.

Accceleration—New types of control have been developed, one of which has a larger number of resistance setps and another of which has the feature of automatic acceleration. Both of these give a much smoother acceleration. By eliminating the jerky starting which accompanied the use of older types of controllers, the discomfort to the passengers from this source has been reduced.

Trucks—The design of trucks has been materially changed in an endeavor to improve riding qualities and reliability, and to reduce weight. While the older type trucks had rigid bolsters and stiff elliptic springs, the newer type trucks are equipped with swing bolsters, very flexible elliptic springs and coil springs. Many cars are also equipped with roller journal bearings to improve the riding qualities.

Use of safety devices on the cars has contributed in a large measure to the excellent safety record made in Atlanta

SAFETY DEVICES

Aid Materially in

Reducing Accidents

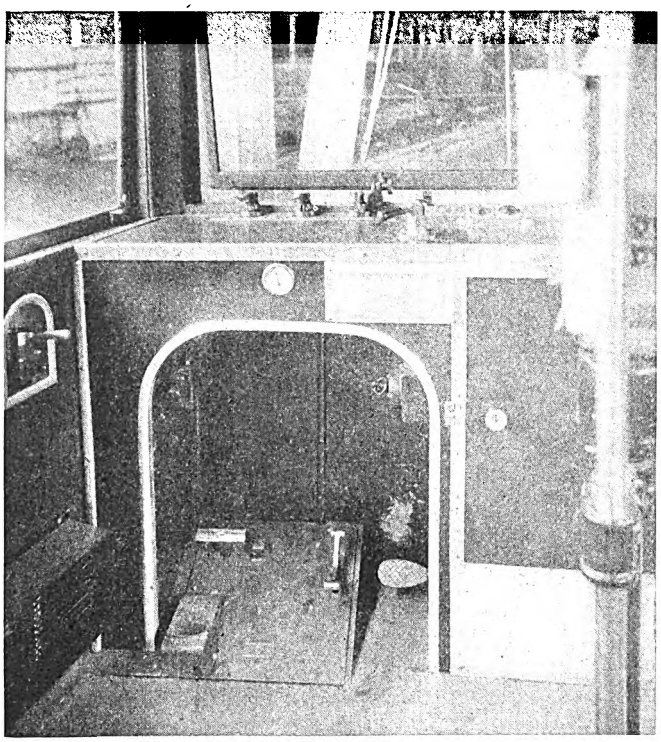
By

F. L. BUTLER
Vice-President
Georgia Power Company, Atlanta, Ga.

ANY PUBLIC utility company worthy of prospering is possessed of a conscience. It is this conscience which, if the company be a public carrier, recognizes the heavy moral responsibility of operating its cars, or vehicles, with the least possible hazard to the community it serves. This moral obligation is one reason for the increasing attention and study which has been given by electric railways in the past ten years to the reduction of accidents involving the public. An additional incentive to safe operation is the ever-increasing cost per claim to the company.

The often-used expression, "no accident is unavoidable," is probably true, but not from the standpoint of just one of the parties to it. Certainly many of the accidents involving the cars of a street railway are unavoidable as far as the company is concerned. Yet on the other hand, it must be admitted that the railways, even the best of them, have a long way to go before

Digitized by Google



Foot control and convenient, plainly-marked auxiliary control handles simplify the duties of the motorman and make operation safer

they have done all that they can and should do to eliminate the accidents which, through effort on their part, are avoidable.

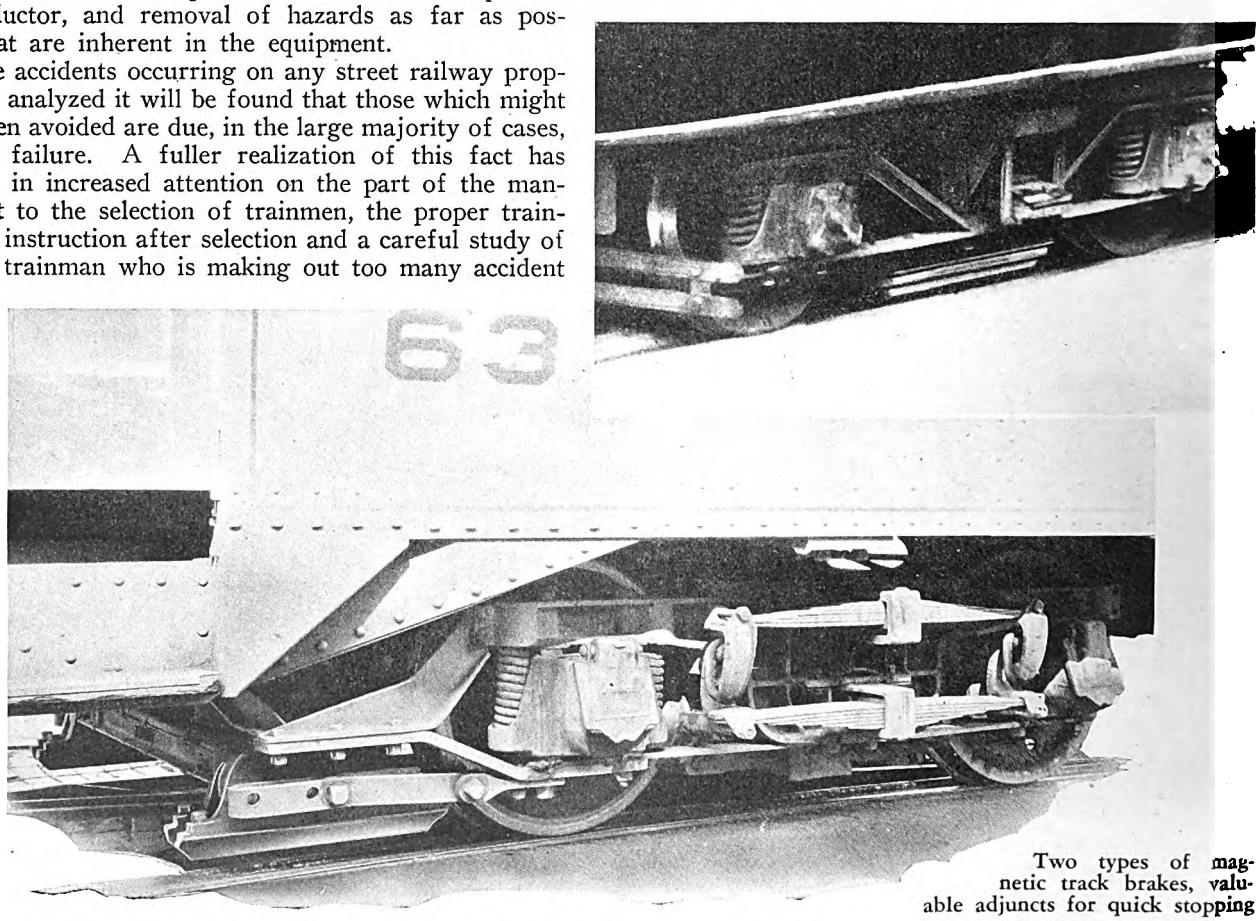
Activities pertaining to accident reduction divide naturally along two lines: reducing the number of cases of man failure on the part of the motorman, operator or conductor, and removal of hazards as far as possible that are inherent in the equipment.

If the accidents occurring on any street railway property are analyzed it will be found that those which might have been avoided are due, in the large majority of cases, to man failure. A fuller realization of this fact has resulted in increased attention on the part of the management to the selection of trainmen, the proper training and instruction after selection and a careful study of the old trainman who is making out too many accident reports. The greatest results can be obtained by upgrading the man who operates the equipment. However, much can be done to reduce those avoidable accidents which are charged to the equipment.

Taking the electric railways of this country as a group, it can be safely said that equipment is being more efficiently maintained than at any time in the history of the industry. This may be partly because of necessity, but it is in the interest of better service, as dependable service is better service. At the same time well maintained equipment is safer equipment and results in fewer accidents.

With the advent of the one-man car many new safety features and devices came into use and improved safety records have resulted. It is fundamental that divided responsibility creates a tendency to let the other fellow do the job with the result that, on cars operated by two men, accident hazards that either might avoid are overlooked by both. The one-man car puts the job directly and solely up to one man, as it should be.

To the public, ignorant of the many safety devices with which it is equipped, the one-man car does not appear as a step toward greater safety. A proper understanding of the equipment in use on the modern one-man car would clear up many misunderstandings on their part in regard to the safety of this type of car. In the industry itself there are also differences of opinion as to the value of various safety devices that have been designed and put on the market to assure the safe operation by one man of a street car through the busy streets of large cities. The question as to whether or not certain equipment should be installed on a car should not be decided from a standpoint of the first cost or maintenance cost. Executives and officials responsible for the operation of cars should realize their responsibility to the community



Two types of magnetic track brakes, valuable adjuncts for quick stopping

Digitized by Google

and see that every precaution is taken so that the operation of the cars will cause no undue hazard to pedestrians or other users of the streets.

Very often a car can be so burdened with safety apparatus that its operation not only becomes complicated but also the speed of the car is reduced. In an effort to make up lost time the operator may possibly have an accident that would not have occurred if his attention had been on the operation of his car rather than on maintaining his schedule. Simplified control is in itself a measure of safety.

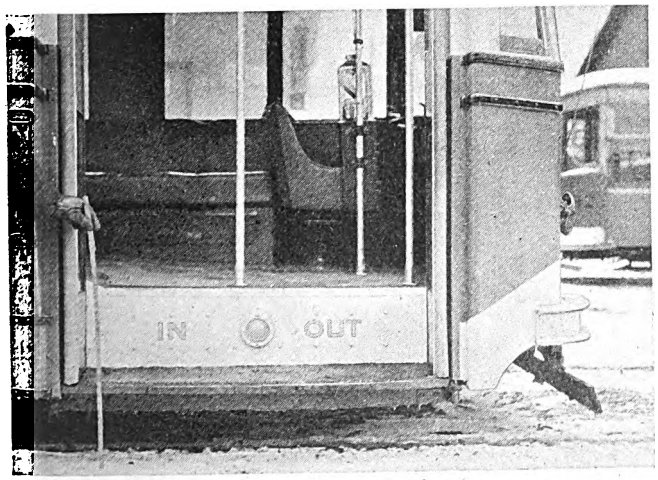
In discussing the devices and methods in use on the modern car only a short outline of their purposes and their advantages and disadvantages will be given.

"Dead Man" Controller—The "dead man" feature of the controller handle which is so arranged that the handle is depressed against a slight upward spring pressure, has been the subject of considerable discussion among operators. Having had some cases, however, when operators have fallen dead at their controller and other cases when they have fainted or otherwise lost consciousness, this feature, in the opinion of the writer, is a very important adjunct to the one-man car. Certainly its use has enabled companies to introduce successfully the one-man car. Of course, the type of accidents it is designed to prevent are rare and may possibly never occur on a small system. However, if an accident should occur from this cause, the result might be so serious as to cause legislation against the use of one-man cars.

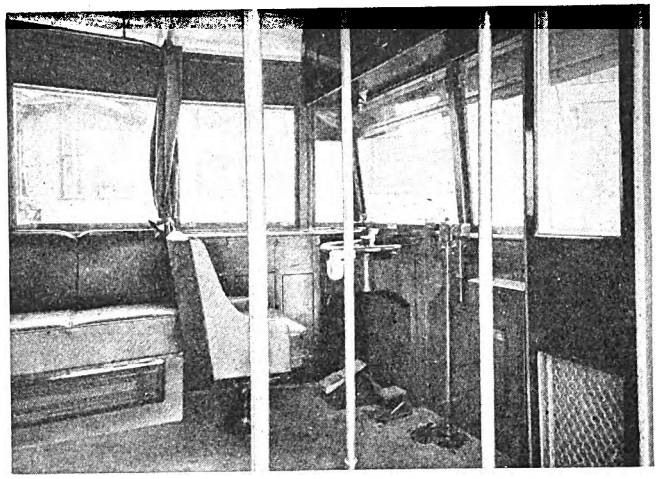
Magnetic Brakes—There is no discounting the value of the magnetic track brake, but the cost and the difficulty of application to a great many existing trucks has curtailed the use of this valuable adjunct for quick stopping. Certainly its value is increasing with the higher speeds of the modern car and the increased congestion in city streets. It has the advantage of being the only type of brake that is affected but little by rail conditions. It is not unlikely that this type of brake will receive a great deal of attention in the near future.

Dynamic Braking—The use of dynamic braking is not very extensive at present. Its use requires ample power and often, with larger motors, commutation troubles develop. As a safety factor its value is still questionable since its ability to stop the car is limited by wheel slippage.

Air Brakes—Operation of the conventional air brakes has recently been speeded up by the installation of quick-application and quick-release valves, and more recently by the coming into use of an improved "self-lapping" brake valve, which is designed so that cylinder brake pressure corresponds to brake-handle position. This valve should have a tendency to reduce lost motion in braking, due to the habit of some operators of "fanning" with the brake valve handle.



Passenger safety in boarding and alighting is increased by low step heights, step lights and properly-located stanchions



Mirrors, windshield wipers and wide vestibule windows aid the motorman in avoiding accidents

Window Guards—Window guards detract from the appearance of the outside of the car and also increase the difficulty of window cleaning. Nevertheless, it must be admitted that window guards serve to reduce the number of accidents, unless track centers are unusually wide.

Window Wipers—Certainly no one would drive an automobile these days without an automatic type of window wiper. Certain designs of window wipers for street cars are a great help during storms, and in cities where single-end cars are in use, the use of window wipers should be considered as essential. In cities with double-end equipment, however, it is difficult to keep them on the cars and to keep them in proper operating condition.

Motorman's Mirrors—Motorman's mirrors are located in two positions, one on the inside of the car and the other on the vestibule corner post outside. The purpose of the inside mirror is to enable the operator to see his passengers and also to get a vision of the rear door. To accomplish this purpose to the best advantage, the location of the inside mirror should be such that the reflected beam is over the heads of seated passengers on the right side of the car. If the mirror is located, as in general practice, so that the beam is reflected down the aisle of the car, a few standing passengers can defeat the purpose of the mirror.

The outside mirror is probably more effective in preventing step accidents, but in cities where automobile and truck drivers are not accustomed to projecting accessories it would be a difficult matter to keep them from being destroyed. Also, with loaded aisles or platforms, passengers standing on the platform between the rear end and the front end of the car would seriously interfere with the operator's seeing what is going on at the rear door.

Warning Signals—There is a need for a satisfactory electric gong which, up to this time, has not been developed. At present, the air-operated gong is probably the most used method of warning signal for city service. Eliminating the trouble from air leakage and freezing during the winter months, to which they are more or less

Digitized by Google

susceptible, they are moderately successful for city use.

Interlocking Door With Brake and Controllers—A number of cars were brought out with rear door interlocking both with the controllers and the air brakes. This combination made it impossible for the operator to start the motors or to release the brakes until the rear door came almost to the closed position. This resulted in longer stops. Some companies have removed both the interlocking features; others have removed the brake interlocking device but have retained the electric interlock between the rear door and the controller. Both features have certain advantages in accident prevention work but evidently the disadvantages have been such as to convince certain operators that their use is not essential. On our property the brake interlocking has been dispensed with. However, the interlocking between the rear door and controller is considered an important feature and is still retained.

Air Compressors—Proper pressure of air in the reservoir is one of the essentials in safe operation. The present type of air compressor has generally proved reliable, but a reduction in weight and the elimination of the commutator end bearing would be desirable.

Variable Load Brakes—While variable load brakes have always had certain advantages, the introduction of the modern light-weight, high-capacity car has increased these advantages so that now we consider them a necessity.

Electro-pneumatic Door and Step Control—On one-man cars where the passengers board at the front and leave at center or rear exit doors, the electro-pneumatic door and step treadle are necessary features. The exit door should be connected with signal lamps in front. Some operators claim that signal lamps are more efficient, because the rear-door mirror distracts the motorman's attention from the front of the car and because they are not absolutely dependable. Similar criticism might be made of signal lamps as they may burn out. Their replacement, however, is simple.

The various requirements in different communities for a safe vehicle make it impracticable to lay down an arbitrary standard for which safety devices should be installed on the ideal car. All operators with the proper understanding of their responsibility to the community will equip their cars with all necessary safety features to meet the requirements on their property and will have their trainmen thoroughly instructed on the proper operation of their equipment. It should be borne in mind that the cost of a serious accident does not stop with the payment of claims, as accidents are given a great deal of newspaper publicity and discourage the use of the service so that the loss in revenue from one serious accident may go on for years. Whenever the problem is squarely met and fairly solved the return in accident prevention and in improved public relations will more than justify the cost of equipping the cars and the cost of an efficient instruction department.

MANY benefits are derived from the use of automatic control. Rapid progress is being made by the Sacramento Northern Railway in converting fifteen of its seventeen manually operated substations to automatic control. When the work is completed there will be a total of nineteen automatic and two manually operated stations having a capacity of 11,100 kw.-hr. In addition to this, the power company furnishes direct current to our lines from five of its substations at various locations. The voltage is more evenly distributed through automatic control, as the machines are governed by the power demand. Extremely satisfactory results thus far have been obtained from twelve stations which have been converted.

Bus Transportation

Developments in bus design have made this vehicle suitable for a wide variety of transportation uses

Improving the Bus to INCREASE ITS USEFULNESS

CONTINUED improvement in bus design is having a marked effect on the growth of bus use in connection with local electric railway operations. Bus designs are now available for a wide variety of traffic conditions found in city operation. Almost any seating capacity can be secured. The most popular sizes, however, are those with 21, 29, 33 or 40 seats, with some few operators still utilizing double deckers of even larger capacity.

The growing popularity of the bus is not surprising when the comparatively small investment necessary to furnish service and the ease with which credit can be obtained are considered. Nearly half the investment in an electric railway must be buried in the ground in the shape of tracks and paving, which have little or no value for any other purpose, while adequate bus operation can be furnished for approximately the same investment that would be required for the railway cars alone.

Nothing emphasizes this fact more than the rapid increase in the number of cities where rail and bus services have been closely co-ordinated. In the seven years ended Dec. 31, 1929, the number increased from 177 to 357; and in the first four months of the current year the number of cities has shown a further increase, although complete figures are not available to show the exact number.

During this period, the sphere of the bus has greatly changed. A new conception has arisen as to how buses can be economically used in connection with electric railways and as a co-ordinated part of a local transportation system. At first, buses were looked upon merely as potential feeders to existing rail lines, in order that the railway investment might be preserved without loss to security holders. But the patrons of these feeder routes failed to take kindly to the necessity of transfer from car to bus and it soon became apparent that unless through bus routes were operated into the business centers of the community, the traffic would not support the bus service. The bus service, instead of being profitable as was anticipated, incurred losses that could not be absorbed. Then followed the idea of changing the feeder bus lines to through bus routes, the gradual elimination of poorly patronized trolley lines, and the substitution of suitable capacity buses.

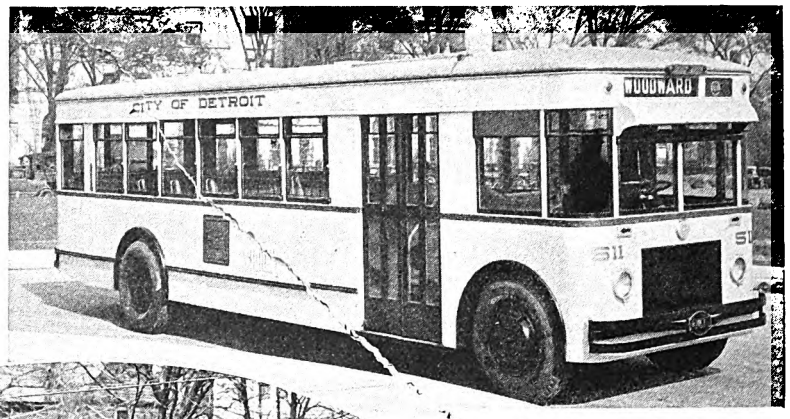
Buses are now being successfully used in a wide variety of ways for handling local traffic. The extreme flexibility of this easy riding, rubber tired transportation unit has demonstrated that it has many advantages both

Digitized by Google

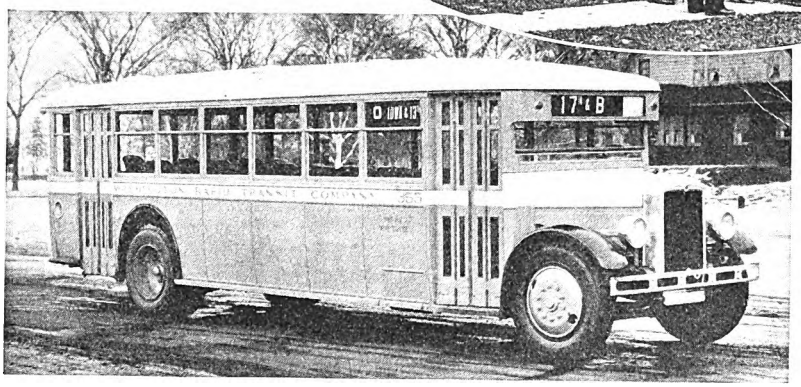
to the traveling public and to the transportation merchant. Instead of making extensions with track, buses have been used to develop new territory. Many single-track trolley routes have outgrown their usefulness and the bus is now giving better and more frequent service. Except where the volume of traffic to be handled can justify the investment for double-track railway lines, buses usually can perform with better results.

But what are the significant developments in design that have brought about this changed viewpoint toward the motor bus? From a transportation standpoint there is a bus for almost every traffic need and almost any seating capacity can be obtained. The more recent designs have adequate headroom to permit standees being carried without discomfort. For routes with extra heavy traffic or where there is considerable interchange of passengers en route, the body is fitted with a rear exit door. These doors are either manually operated by the driver or are treadle controlled and air operated. Interior illumination is better. Ventilation has been improved, although there is still opportunity for further development. The use of direct exhaust heating is gradually disappearing and in its place has come forced-draft hot air or hot water heating. Nevertheless, the obnoxious smell of burnt gases in the engine exhaust too often permeates the body interior. In cold weather it is especially noticeable with a following wind and in the warm weather it rolls in the open windows when the vehicle stops to pick up or discharge passengers. Even with the tail pipe at the rear this trouble still exists.

Nothwithstanding these defects, the bus is steadily growing more popular as a medium of transportation. It is fast; its acceleration is improving; and the time which is lost due to low acceleration is made up in smooth rapid braking, for the modern bus has a retardation with airbrakes of from 10 to 12 m.p.h.p.s. without excessive discomfort to passengers. This is far greater than is ordinarily obtained on steel rails.



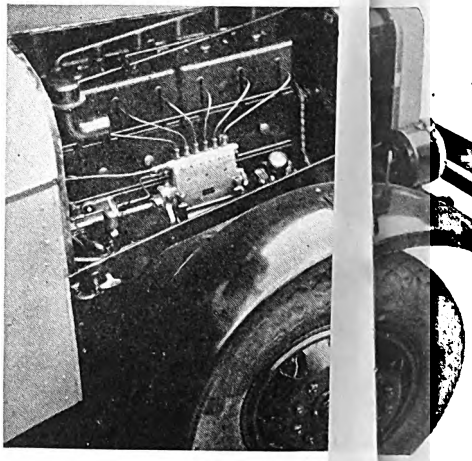
Larger capacity buses are one of the most important recent developments. For routes on which there is heavy passenger interchange, many are equipped with rear-exit doors



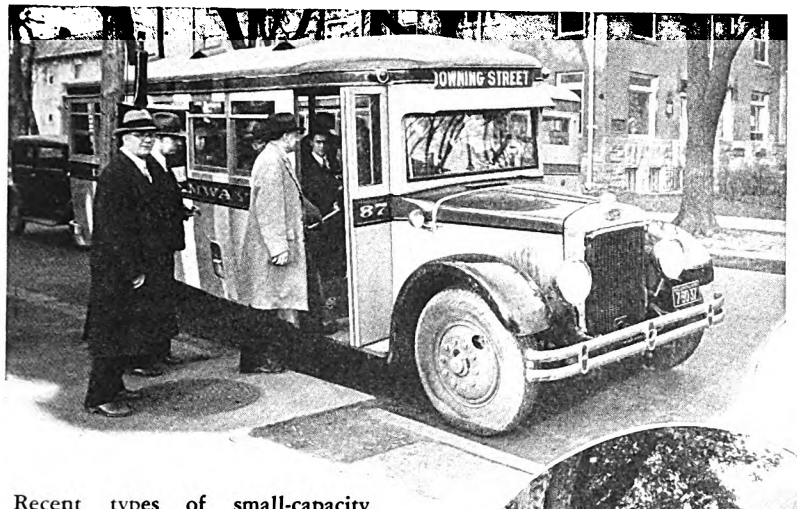
From an engineering viewpoint developments in bus design have been extremely rapid. One design has followed another with such rapidity that style and mechanical obsolescence have become factors of considerable importance for the operator. Probably no other use of the gas engine has had to meet such rigorous demands. The same can be said of the clutch and gear set. Notwithstanding this, engines have increased steadily in size and horsepower to meet the demands of the transportation service for which they are intended. In fact, engines and body shell are competing for chassis space, even though wheelbase has grown from 198 to 265 in. In the larger capacity vehicles of conventional type, the engine now protrudes into the passenger compartment. Weight distribution has thus become a factor, not only in steering facility but in tire life. Whether or not six-wheelers will again come to the front is a question that remains unsettled.

Outstanding, perhaps, is the development of the power plant. Starting with four-cylinder engines of less than 300-cu.in. displacement and rated at substantially less than 50 hp., both the displacement and horsepower have been steadily increased. Today the four-cylinder engine has been

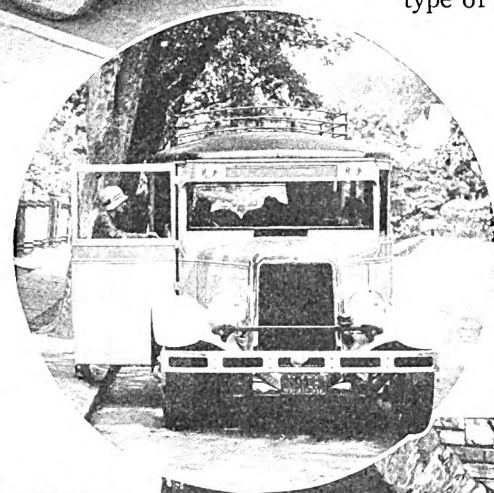
Six-cylinder Diesel bus engine used in experimental work by Public Service Co-ordinated Transport

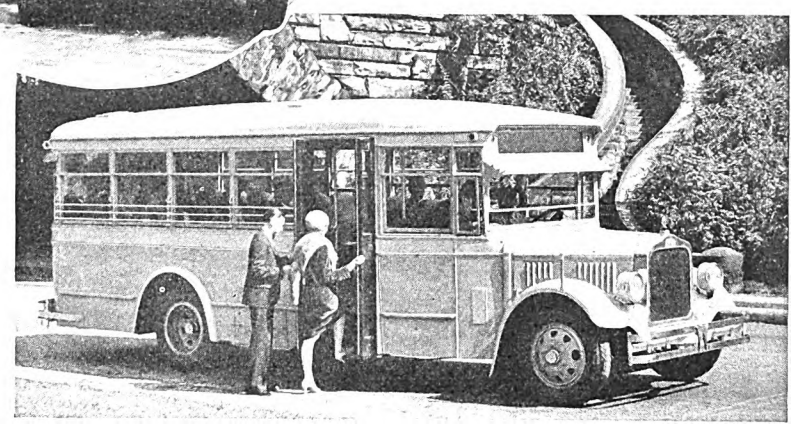


Digitized by Google



Recent types of small-capacity buses for city service

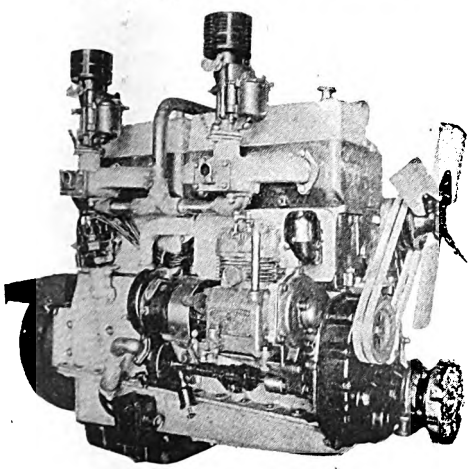




almost entirely supplanted by the six in order to meet the demand for better acceleration, faster schedules and smoother running, all of which are deemed necessary to compete with the ever increasing private automobile competition. In one instance a manufacturer has used dual engines. Engines found in the larger buses of conventional type have a displacement of from 450 to 600 and more cubic inches and a rated horsepower of 85 to 150. The rate of acceleration has likewise increased, though not in direct proportion to this greater displacement.

A word should be said with regard to the gas-electric type of drive. This unit has proved itself of value in cities where bus routes are operating in a larger measure through heavy vehicular traffic. In such places, the turn-over in passenger traffic is naturally heavy and often requires from twelve to fifteen stops per mile. Gear shifting under such conditions of operation is a severe strain on the driver and the varying rate of acceleration is annoying to passengers. It is in such service that the gas-electric unit has proved most satisfactory.

Recent designs of bus engines give greatly increased power. This is a six-cylinder 150-hp. type



Much progress has been made in the design of several of the important gas-electric bus units and the excess weight formerly found in chassis of this type has been materially reduced. Satisfaction with these units for city service is best demonstrated by the steadily increasing number of carriers using these vehicles.

Recent experiments conducted by Public Service Co-ordinated Transport, the largest single operator of gas-electric vehicles, with a six-cylinder Diesel bus engine to drive the generator should not go unmentioned. It is understood that other companies are exceedingly interested in this Diesel-electric combination and it is confidently expected that within the next year there will be several other installations in the eastern part of the country.

Next among major improvements comes that of the brakes. The manually operated type of brake has largely been superseded by some form of power brake for two reasons: first, to assure greater safety to passengers and to other highway users; and, second, to relieve the driver of considerable physical effort and resulting fatigue. Fabric linings and two-wheel brakes on the rear axle or a single brake on the propeller shaft have given way to the four-wheel type of power-operated brakes using some form of molded linings. Steel shoes were tried at one time but current practice leans heavily toward molded linings today. The use of these substitutes for fabric linings permits the use of higher braking pressures and consequently produces higher rates of retardation. These changes permit faster and safer operation in traffic lanes that are used by other vehicles fitted with four-wheel brakes and capable of stopping quickly.

So much for the chassis in general. With the continued demand for vehicles of even larger capacity and ability to carry the maximum number of standees, the manufacturers have been beset with the problem of furnishing deeper and heavier frames with more substantial cross members and body outriggers. For this reason, bodies have had to be built more substantially, thus causing unforeseen stresses to be set up between the frame and outriggers due to chassis weaving. The net result has been a battle between the chassis and the body. Instead of the frame holding up the body, the body at times holds up the frame until outriggers become distorted or broken, or the body gives way at its weakest point. It seems that there is yet much to be learned through experience as to body stresses. Whether existing designs

Digitized by Google

or methods of mounting will be discarded is difficult to say at this time, but it is evident that something needs to be done that will permit the chassis to become the load-carrying unit under any and all road conditions. One manufacturer has developed a four-point system of attaching the body to the chassis frame in an effort to eliminate transferring the body stresses, due to weave, to the frame.

Notwithstanding that over-all weights are greater on a passenger-capacity or seat basis, much progress has been made toward more effective utilization of weight-saving materials. A great deal yet remains to be done, of course, and if fuel consumption is to be reduced, one way is through greater use of light-weight alloys for strength supporting members of both chassis and body. Analysis of weights on the basis of pounds per cubic inch of engine displacement also indicates that marked progress has been made.

In refinements and redesigning of unit parts to give longer service without increased attention many advances have been made. Bus engines now reflect the last word in power and performance. The sleeve-valve engine still holds its popularity for heavy-duty city service. For use in connection with electric motor driven units, the overhead-valve type engine is being more extensively used. Noiseless and more effective tappet features have been included in the valve mechanism of this type engine by one manufacturer. Other features of the modern engine are the use of steel-backed bearings for the crankshaft or the so-called chocolate bearing, both of which are intended to produce longer life and consequent lower maintenance costs. Alloy pistons, forced feed to all wearing parts, such as pins and rod bearings, oil filters and counterflow oil circulating systems, all are playing their part in reducing engine maintenance.

Nevertheless, as the engines have increased in size not all of the increased power has become available for direct propulsion purposes. Larger engines naturally require more power for auxiliaries. Fans are larger and their operation takes a proportionately greater amount of engine output. Water pumps and oil pumps are also of larger capacity. The same is true of lighting generators and air compressors. These all demand more power. Hence all the gain in effective horsepower can not be said to go to the driving wheels. Some of these power demands have been lowered through closer study of the operating characteristics of the auxiliary units. Oil cooling is another feature recently considered, but this practice is far from being universal in the design of all types of engines.

As has been noted, real progress has been accomplished in engine design. Speeds have been decreased for the maximum torque with the result that the lineal piston speeds have been held within reasonable lubricating bounds. Compression ratios have also been stepped up to permit the use of low grade fuels without too much loss in power.

Tire developments can not be overlooked. The progress made by the tire manufacturers in selling service by the mile has produced one bright spot in the expense accounts. Tire construction has been materially improved through the use of a greater number of plies and the mileage secured from these tires is far more than at any time heretofore. The development of the heavy-duty balloon type to meet the increased weights of buses and their greater passenger capacities has increased the comfort of bus riding. What was once considered a rough road has thus been smoothed out if proper air pressures are maintained in the tires. High-pressure tires are now almost unknown, except on the older types of buses, and tire costs under the mileage contract system have materially decreased within the past few years. The rate of 1.5 cents has decreased to 1 cent or less, even with service, a figure that is difficult to meet where tires are purchased outright and maintained by the carrier.

Success in bus operation is not accidental. It can be secured only by selection of the proper type and capacity vehicle, backed up by an adequate inspection and maintenance plan to give dependable and reliable schedules. Because no two systems are alike, because road conditions between different systems are not uniform, because traffic conditions vary, and because driver training is different on each property, there can never be a standard inspection and maintenance plan. True, the methods followed can be similar but the period between inspections and their thoroughness, whether based on vehicle-miles operated, on engine revolutions, on kilowatt-hours generated, or gasoline consumption, or any other unit, must be worked out independently for each separate operating system. Every property must of necessity experiment with inspection periods of varying duration until the one best suited for the property in particular is developed.

What the future will develop in the way of further requirements in design is difficult to foresee. It is evident, however, that closer attention has soon to be paid to decreasing the weights of chassis, body shell and accessories. One way can be through greater use of lightweight alloy metals; another through simplification of accessories and the elimination of devices and attachments that are not essential to passenger convenience. Close study of the weight problem is but one of the factors involved in profitable operation at the rates of fare now current in most cities. With operating costs varying directly with the number of vehicles required for peak load conditions, it is essential that proper selection of the vehicle be made and that rush hour vehicles be of larger capacity. In order that this may be done effectively, a careful analysis of route and vehicle costs must be made periodically. With operations properly conducted there is no reason to doubt the important part that bus operation will play in the future of local transportation.

The latest type cars of the Boston-Cambridge subway accelerate and decelerate at approximately 1.75 m.p.h.p.s. and have a free-running speed of 40 m.p.h.

Answering a GROWING NEED *for* Adequate Rapid Transit

By

EDWARD DANA

General Manager

Boston Elevated Railway, Boston, Mass.

AMID all of the confusion regarding the future methods of handling mass transportation in cities there is one conviction that stands out prominently. It is that the backbone of the transportation system in very large cities is bound to be rapid transit. The very conditions which are making surface transportation more and more difficult are correspondingly making rapid transit more and more necessary.

In testimony given last summer before the ways and means committee of the Massachusetts Legislature, I summed up the situation regarding rapid transit somewhat as follows:

"The need for adequate rapid transit has been accentuated in recent years by the increase in private motor-vehicle transportation. This type of transportation is most extravagant in the use of street space and has led to a condition of delay and waste time. Individual transportation by automobile will probably increase, but it should go hand in hand with adequate mass transportation facilities if the city is to prosper. The situation is illustrated by the following table, showing the relative capacities for delivering passengers for a maximum one hour in one direction:

Automobiles can transport (100-ft. streets, three lanes)	4,100
Buses can carry (maximum performance record on Fifth Avenue, New York)	7,300
Street cars	13,500
Two-track rapid transit	60,000
Express and local-track rapid transit	115,000"

In a few cities in the United States there are now sections where surface transportation is already out of the question. If skyscrapers continue in favor and automobiles are allowed freedom of the streets, in every very large city there will have to be rapid transit in the congested sections. This will extend as far out as economically possible, connecting with surface car lines and bus routes at the edge of the rapid transit district.

It is to be expected, of course, that there may be a reaction against excessive centralization of business. But this will not reduce the demand for rapid transit, because the new centers which must necessarily be developed will need rapid transportation connections.

Rapid transit is one phase of the solution of

Type of steel elevated car which has replaced a large number of wooden cars in Boston. It is equipped with one motor truck and has a running speed of 36 m.p.h.

the mass transportation problem about which it is impossible to generalize very much. Only the fundamental principles are applicable in all communities where rapid transit is feasible. Every large city has its individual characteristics which affect its rapid transit requirements and possibilities. In metropolitan Boston, for example, where the streets are narrow, crooked and hilly in the downtown section, the topography of the main business district is such that the effects of street congestion were early felt. Traffic flows, as it has for 300 years, from all directions into and out of the small peninsula which is historic and commercial Boston. Two-thirds of all the people entering this section use the "L." As I have stated before, Elevated transportation is the very life-blood upon which the industries and retail business of Boston depend.

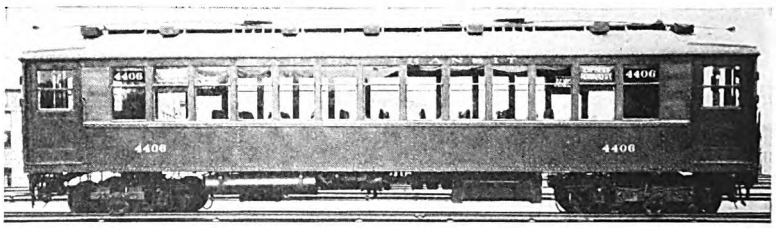
Rapid transit in general, as illustrated in Boston, is undertaken primarily to save time for patrons. It is safe to say that the saving over even favorable surface line transportation is 50 per cent. Time saving in rapid transit results from obvious advantages, principally freedom from traffic interference, reasonably economical spacing of stops, and ability to use the types of rolling stock best adapted for speed.

On the rapid transit lines of the Boston Elevated System the demand for speed is met to this extent: over the 8.5 miles of main-line elevated route the running time is 30 minutes; the 4.1 miles route between Dudley Street and North Station (via Atlantic Avenue) is covered in 15 minutes; between Harvard Square and Ashmont (9 miles) the time is 25 minutes. The rush-hour headway on the main-line elevated and between Cambridge and Ashmont is two minutes, with a normal-hour headway of four minutes on the former line and 2½ minutes on the latter.

How the Running Time Is Kept Down

Speed of operation, aside from duration of stops, depends on running speed, rate of acceleration and rate of braking. Efforts of engineers are constantly being directed to increasing these quantities without exceeding cost limitations (first cost and maintenance) and without making riding uncomfortable for passengers.

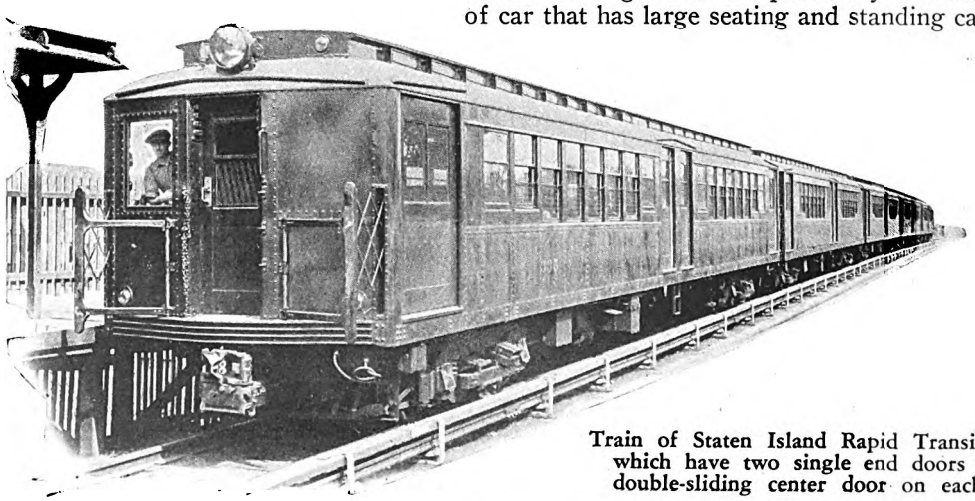
In Boston we are using an accelerating rate of 1.75 m.p.h.p.s. in the Cambridge subway and East Boston tunnel with unloaded cars, and 1.5 with cars carrying seated load. The braking rate is 1.75 m.p.h.p.s. The elevated cars accelerate at 1.5 m.p.h.p.s., light, and at 1.3 m.p.h.p.s. with seated load. The braking rate is from 1.5 to 1.75 m.p.h.p.s. The free-running speed is 36 m.p.h. in the Cambridge subway and 40 m.p.h. on the same route in the open. The speed in the East Boston tunnel is 30.5 m.p.h. and that on the elevated is 36 m.p.h. These rates have proved adequate, but research is constantly in progress looking to possible improvement. We feel that quick pick-up and stopping are just as good sales points for mass transportation as they are for the automobile.



Recent type of Chicago Rapid Transit elevated car, using cross seats, an unusual practice for heavy service

The Rapid Transit Car Is the Crux of the Problem

While rapid transit has many other valuable features, an outstanding one is the possibility of designing a type of car that has large seating and standing capacity, high-

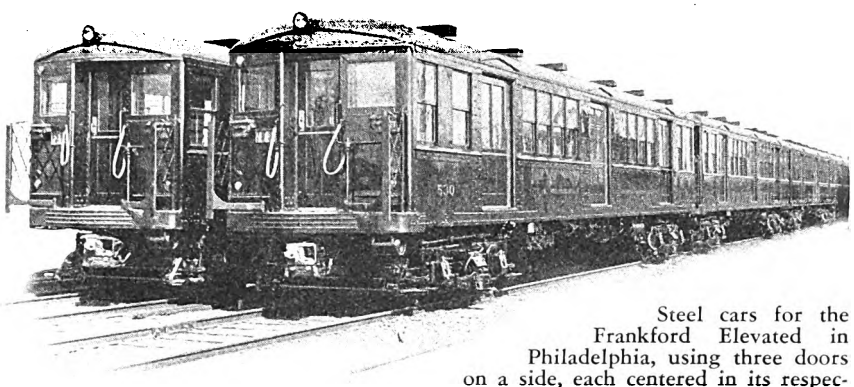


Train of Staten Island Rapid Transit cars which have two single end doors and a double-sliding center door on each side

Digitized by Google

speed characteristics, quick pick-up and braking, etc. It will be of interest to consider some of the elements of modern rapid transit car design.

Of course, cars should be designed to present as pleasing an appearance as possible, although this feature may be complicated by some limiting condition in connection with window openings, letter boards or other governing considerations. During the past few years, street cars have been greatly improved in appearance. With rapid transit cars, however, there is not the same opportunity to vary the design aside, possibly, from the arrangement of doors, windows and roofs. Limiting conditions of tunnels usually definitely fix the car dimensions.



Steel cars for the Frankford Elevated in Philadelphia, using three doors on a side, each centered in its respective third of the car

The most practical arrangement of rapid transit car doors is one wherein the distance a passenger must walk, lengthwise of the car from the door opening to a point midway between the doors is the shortest possible and is equal throughout the length of car. This is accomplished by providing three doors in the side of the car. one at the center and two at points two-thirds the distance from the transverse center to the end of the car. With this arrangement a more uniformly distributed standing-passenger load is obtained. This, in turn, means a larger capacity than will result if the doors are arranged one at the center and one at each end of the car.

In the latter case the load is localized about the doors, with considerable available space in the area midway between them. This is true particularly in cars having longitudinal seats with a large standing area the full length of the car. Where a combination of cross and longitudinal seats is used, the condition is, perhaps, somewhat different. But even in this case, if the longitudinal seats are placed adjacent to the doors and the doors are located as in the first instance, the maximum standing load is obtained.

From the standpoint of handling the greatest number of passengers per unit, the longitudinal seating arrangement is superior to others. In the time required for loading and unloading of passengers, there also is a decided advantage in longitudinal seats in combination with the first door arrangement mentioned. The distance which it is necessary to travel to reach the door is shorter and there is freer movement of passengers due to the wide space between seats.

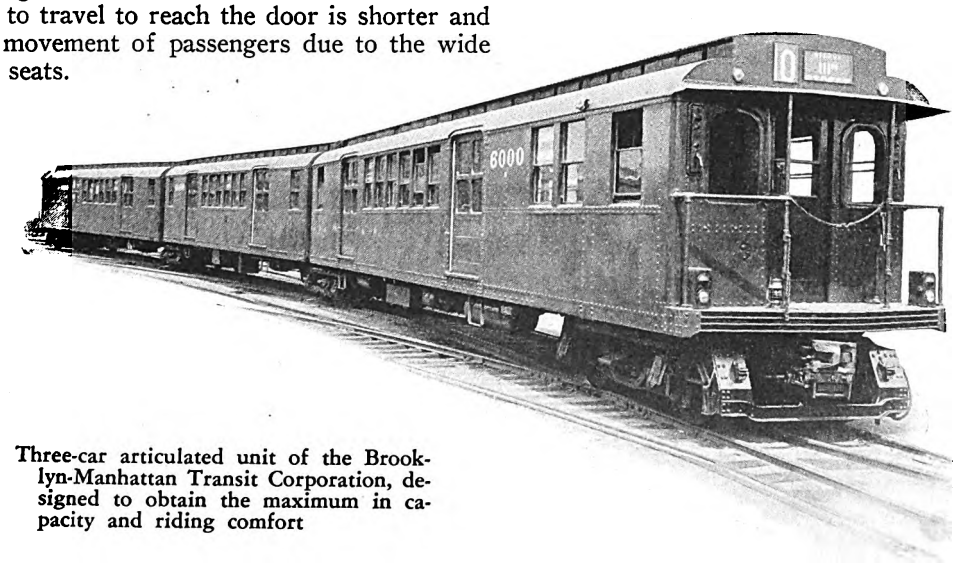
In rapid transit cars, floors of non-slip material should be provided, and door thresholds or other metal parts should be of such a design as to reduce to a minimum the possibility of passengers tripping or slipping. Sufficient stanchions, hand holds or grab handles should be provided to permit a passenger to support himself properly while the car is in motion.

On the question of seats, experts differ as to whether there is an advantage in providing soft upholstered seat cushions and backs, or whether some other seating material is better. In this matter I believe that for city rapid transit service, where the length of ride is comparatively short, leather upholstery is not desirable. Cushions and backs of wood slats, if of the proper contour, are perfectly comfortable and are preferable to leather from the standpoints of sanitation, durability and maintenance.

Provisions For Passenger Safety

It is the duty of everyone connected with car design to take all possible precautions against accidents to passengers and to operating men, including the shop men who maintain the equipment in first-class operating condition. To this end, doors should be provided with collapsible or rubber door bumpers which will permit a person to withdraw his arm or foot, in case he is caught in a closing door. Electric switches or apparatus of any kind which are involved in the operation of the car should be so located that passengers will not have access to them.

The question of weight of equipment is one which should receive careful consideration in the construction



Three-car articulated unit of the Brooklyn-Manhattan Transit Corporation, designed to obtain the maximum in capacity and riding comfort

Digitized by Google

of rapid transit cars. On the basis of a given operating cost per pound per year, it is obvious that the light car is more economical in operation than the heavy car. In addition to the saving in operating cost, there is a saving in first cost in body, trucks and motors. Weight, however, should not be reduced to the point of sacrificing the necessary strength for proper protection against collisions or other accidents. A substantial saving in weight can be effected in the design of any car without sacrificing strength by paying strict attention to the detail and design of small parts where the question of strength is not of great importance.

Boston's Latest Subway Car

In determining details of the present standard car for the Cambridge subway, of which 60 were recently commissioned, the considerations mentioned above governed the selection. The specifications have been published so that I need mention only the doors, which are in number three on a side and located as recommended above.

The doors on these cars are of wood, aluminum-covered, arranged to slide on the exterior of body and actuated by electric door operators. The result is light weight, and low original and maintenance cost. Moreover there are no door pockets, and no accumulation of snow experienced in the older type with pockets. The inside width of the car is greater than with inside-hung doors, and the unavoidable waste of compressed air with air-actuated door engines is eliminated, as well as the trouble experienced from freezing and slow door movement in cold weather. As compared with steel doors, these doors are approximately 640 lb. lighter per car.

The electric door operators are located under the seats, with a shaft extending through the side of car. To this is attached a lever for actuating the door. Operators are controlled from push-button groups at the end of the car, as on the earlier cars equipped with air operators. The end doors slide in pockets, but they are outside the gates, and weather stripping is provided to prevent snow from driving into pockets.

A Necessary Form of Mass Transportation

From my outline of the rapid transit problem, there is no doubt as to my belief in and enthusiasm for this form of mass transportation where feasible. Transportation patrons and prospective patrons want to save time. If convinced that they can do this they will limit the use of their automobiles to non-competitive service. Unnecessary time spent in going to and from business is just so much added to the day's work. It is particularly of the worker that I am thinking in this connection. He is usually compelled to travel in the rush hour when travel is at its worst as far as comfort is concerned. The less the duration of his homeward or workward ride, the less it fatigues him. Travel time saved for the patron is leisure time increased. Thus there is a sociological as well as an economic aspect to rapid transit.

The effect of rapid transit upon general living conditions has often been stressed. It cannot be over-emphasized. Rapid transit enables the worker to live at a reasonable distance from his work and under conditions of his own choosing. From the operating standpoint the high speed and the ability to use car and train units of large capacity offsets, under proper conditions, a large part of the increased capital investment involved in rapid transit. Thus densely settled urban communities of large population can have, and should have, rapid transit.

IN order of their importance, successful commutation service must include (1) trains on time, and (2) adequate lighting and heating. The maintenance of train schedules is extremely important to the commuter who must be at his place of employment or business at a definite time each day. Because he uses his time on the train for reading his newspaper or magazine, the commuter must be provided with adequate illumination. Similarly, because he spends time on trains when otherwise he would be in his home, good heating and ventilation, comparable to that in his home, must be provided.

Recent Freight Equipment Trends

MORE PROFITABLE

By

DAVID R. THOMAS

President Electric Railways Freight Company

Cleveland, Ohio

ELECTRIC railways engaged in the transportation of freight have changed their concept of this business and their methods of handling shipments very fundamentally in the past few years. A steady decline of passenger revenue and a new but powerful competitor, the motor truck, have caused them to take every progressive step possible to attract an increasing amount of profitable freight revenue. Definite policies, adopted for this purpose, are clearly indicated by the types of equipment placed in the freight service of the interurban railways during the past year. They show pronounced trends, on the part of these common carriers, toward:

1. Maintaining faster freight train schedules and using cars of greater capacity.
2. Providing facilities for handling steam road cars on electric railway lines and for moving electric railway freight cars over terminal tracks of steam roads.
3. Rendering pick-up and delivery, door-to-door service.
4. Affording container service.
5. Operating truck lines as feeders to rail lines.
6. Paralleling rail lines with truck lines to meet the competition of competing truck lines.
7. Using mechanical equipment for handling freight at terminals and instituting more efficient warehouse and loading methods.
8. Providing automatic accounting machines with which to reduce accounting expense and provide more comprehensive statistical information.

The accompanying illustrations indicate clearly the complete and comprehensive freight service that is the ultimate goal of the electric railways. Fig. 2, for example, shows the trend in equipment toward faster, better-appearing freight motor cars. Greater capacity, too, is being attained in both motor cars and trailers.

The effort on the part of interurban lines, as distinguished from electrified steam lines, to develop connections with steam roads is also evident. Interurban lines cannot handle steam road cars through city streets but they are endeavoring to utilize sections of their systems located on private rights-of-way for this purpose. Several roads have tentative plans to build around a number of the smaller cities to permit a more extensive use of M.C.B. equipment. During the past year, too, arrangements have been worked out whereby steam lines may

Digitized by Google

handle interurban freight motor and box cars through steam road terminal yards. Only slight modifications in the construction of interurban cars were required to permit this operation.

In Figs. 4-8 are shown the different types of truck and trailer units used in electric railway pick-up and delivery service. The 1-ton tractor and 14-ft. semi-trailer, Fig. 4, is an extremely flexible unit and, with the second trailer to be left at the customer's premises while unloading the first at the freight terminal, is capable of picking up and delivering a surprisingly large amount of freight. The units shown, under favorable conditions, handle from 40,000 to 50,000 lb. of freight per day. The 2½-ton tractor and 20-ft. semi-trailer, Fig. 6, is the type of equipment used for large shipments by the Elway Transit Company, a forwarding company in Cleveland.

The truck carrying a Fitch container, Fig. 7, illustrates the flexibility of this container system. Note the similarity between this unit and any closed-body truck. The container may be carried on a highway trailer as well as upon a truck and is transferable to a railway flat car.

Fig. 2—Latest design of freight car, with a capacity of 80,000 lb., placed in service by the Cincinnati & Lake Erie Railroad. It is equipped with four 100-hp. motors and is capable of hauling twelve electric railway box car trailers at a speed of 45 m.p.h.

Assure a BUSINESS

For the most efficient pick-up and delivery service in the larger cities the equipment required may be roughly grouped into three classes:

1. One-ton tractors, each with two 14-ft. semi-trailers for light work.
2. Two-ton trucks for serving customers so located as to necessitate driving through narrow alleys and for using congested dock facilities. Half of the trucks should be equipped with closed bodies, the other half with stake bodies.
3. Two-ton tractors, each with two 18-ft. semi-trailers; one with stake body, the other with closed body. It will be found that the manufacturers of certain commodities insist upon their merchandise being handled in waterproof vehicles. It is difficult to maneuver trailers that are longer than 18 ft. in many localities.

For service in outlying districts the use of two trailers in train drawn by one tractor is found to be most efficient; the second trailer is converted into a four-wheel trailer by means of a dolly. This same equipment is used in handling tonnage between off-line substations and the rail head.

It is becoming more and more evident that freight service from the door of the shipper to the door of the consignee is to become the general policy of the electric railways. This policy is manifested in varying degrees throughout the country. In Western Ohio and Indiana the railways have gone only so far as to absorb from 3 to 5 cents of the shipper's or consignee's cartage cost on shipments conforming to certain specified minimum weights, and commodity classifications. The shippers and consignees provide the cartage equipment.

In Southern California the Pacific Electric Railway has provided for a complete pick-up and delivery service through the incorporation of the Pacific Electric Motor Transport Company. This company was organized for the purpose of carrying on the business of transporting freight, express and other commodities and of conducting a general receiving, forwarding and warehouse business. The rates of the transport company will cover the complete door-to-door service, or service from the shipper's door to destination rail terminal, or from originating rail terminal to door of the consignee. In the Pacific Electric Railway territory, shipments will be

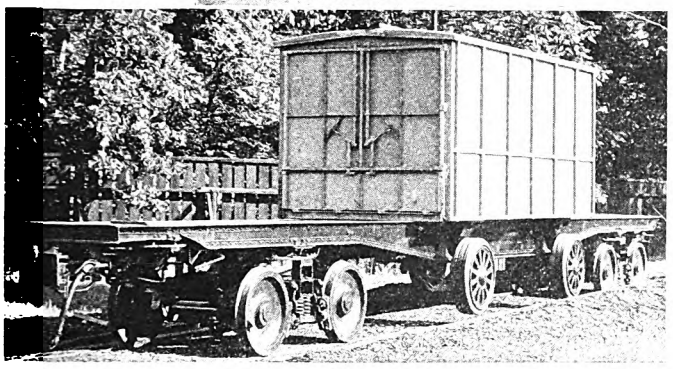

Fig. 10—Trailer of Bonner Railwagon system mounted on railway flat car

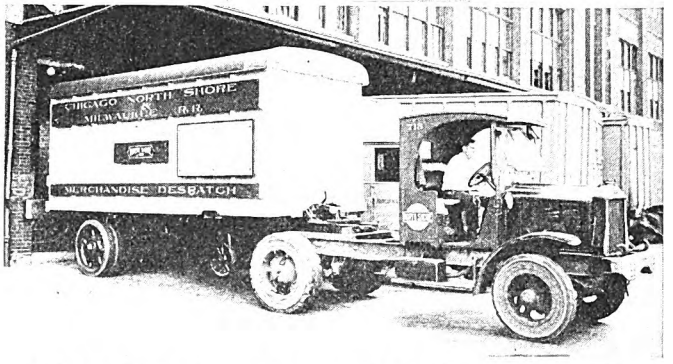

Fig. 11—Type of semi-trailer used by the Chicago, North Shore & Milwaukee Railroad

large shipments moving from one consignor to one consignee, or to several consignees at one destination, and shipments that, if not rehandled at terminals, can be shipped uncrated or unwrapped, are particularly adapted to motor-truck-trailer transportation. The use of containers eliminates 90 per cent of the terminal cost and from 50 to 60 per cent of the pick-up and delivery expense. The container also is, in a measure, a substitute for the steam road side-track, and makes available to the electric railways certain classes of steam road carload business that is not now obtainable because of the handling cost at electric railway terminals.

Figs. 8-11 show the trend of container design. It will be noted that the containers may be divided into two general groups: first, the demountable box type, illustrated in Figs. 8 and 9; and second, the highway trailer type, Figs. 10 and 11.

The box or container of the highway trailer type is in fact a highway semi-trailer that is carried, with wheels intact, upon the railway flat cars. In the Bonner type, Fig. 10, the floor of the container rests upon the platform of the flat car with the wheels suspended on either side of the flat car, below the level of the car platform. The journals of the flat car are placed inside of the car wheels instead of outside, the wheels of the trailer-container occupying the space customarily occupied by the rail car journal boxes, thus maintaining the over-all width of the standard interurban cars. In the case of the units used by the Chicago, North Shore & Milwaukee Railroad, Fig. 11, the trailer-container rides on top of the railway flat car, the wheels of the container resting on the car platform.

In both types described, three trailer-containers, each approximately 18 ft. long, may be carried on one railway flat car. The carrying capacity of each container is 20,000 lb. which permits a pay carload of 60,000 lb.

Several types of demountable containers are now available to the electric railways. The several methods of transferring them from truck to railway car and vice versa include the hoist, electric-lift truck and roll-off. It will be noted that the Fitch container, Fig. 8, is approximately twice the length of the other types of box containers shown. It is 18 ft. long and corresponds to the closed body of a highway truck, the bodies of the containers used by the North Shore, and those of the Bonner system. Three of these containers can be carried on a railway flat car, returning a very favorable per car-mile revenue at a comparatively low container rate. The

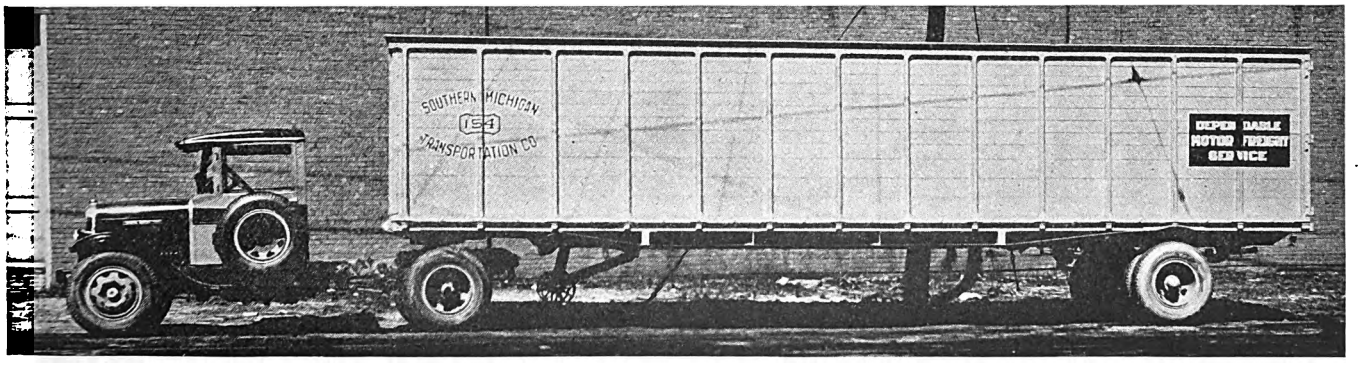

Fig. 12—Thirty-five foot semi-trailer unit of the Southern Michigan Transportation Company, used for hauling light and bulky freight

Digitized by Google

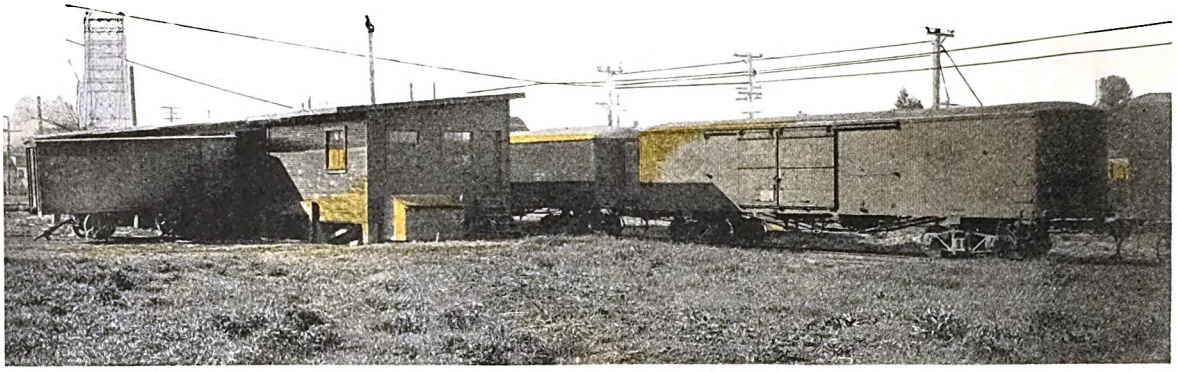

Fig. 13—Railway truck line transfer station of the Lake Shore Electric Railway, Toledo, with a "spot" capacity of four cars

18-ft. container is particularly adapted to meet the competition of the motor freight companies and is an excellent unit to use in connection with feeder truck lines. As a pick-up and delivery unit, the 18-ft. demountable container offers the means of meeting the competition of the side-track facilities of the steam roads.

Several types of highway equipment are now used by the electric railway freight truck lines. Power units usually consist of 2½ to 3½-ton tractors weighing approximately 7,000 lb. and capable of handling two trailers in train. The trailers are 20 ft. long and either of the stake or closed-body type; the second trailer in the train is either a four-wheel unit or a semi-trailer converted into a four-wheeler by means of a dolly. The trailers weigh from 7,000 to 7,800 lb. and have a rated carrying capacity of 7 tons but are capable of carrying from 10 to 12 tons. Fig. 12 illustrates a 35-ft. semi-trailer designed to handle bulky freight such as furniture. Several of these units are in the service of the Southern Michigan Transportation Company, Jackson, Mich.

Fig. 13 shows the Glendale rail-truck transfer terminal of the Lake Shore Electric Railway, located at the eastern city limits of Toledo, Ohio. This transfer has a "spot" capacity of four railway cars and has done much to eliminate congestion at the Toledo freight terminal. Cars loaded and unloaded at this terminal do not pass over the streets of the city.

Fig. 14 — Elwell-Parker electric lift truck depositing skid in freight car

During the past twelve months, a number of electric railways have either acquired truck lines or have entered into traffic arrangements with separately owned motor freight companies. In several instances, too, electric railways have abandoned rail operations and are serving the territory with motor trucks. The Eastern Michigan System, with truck lines radiating out of Detroit, is an example of an organization that is operating motor trucks as feeders to their rail lines, as developers of new territory not served by electric railways, as substitutes for rail lines that have been discontinued and as supplements to existing rail service. The Southern Michigan Transportation Company is giving freight service by motor trucks, having abandoned all of its interurban lines.

Fig. 15—Placing a heavy shipment in a car with an Elwell-Parker warehouse crane

In eastern, central and northern Ohio the Electric Railways Freight Company is directing operations of several truck lines that were recently acquired by the Northern Ohio Power & Light Company. These lines are being operated as feeders to the railways and for the purpose of meeting the competition of other truck lines serving the railway territory. The opinion is held by a number of operators that the railway which renders container service with the truck body type of container will not find it necessary to parallel its rail lines with trucks.

In Figs. 14 and 15 are shown mechanical aids for reducing terminal costs and improving service. The advantages of these are self-evident.

Building BETTER *Track*

By
W. W. WYSOR
Chief Engineer
United Railways & Electric Company
Baltimore, Md.

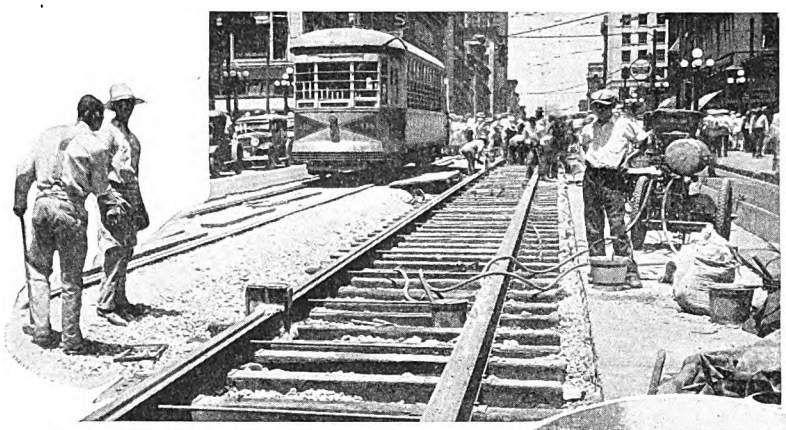
President
American Electric Railway Engineering Association

Tee rail has recently regained a considerable amount of its former popularity for use in street railway track with concrete paving

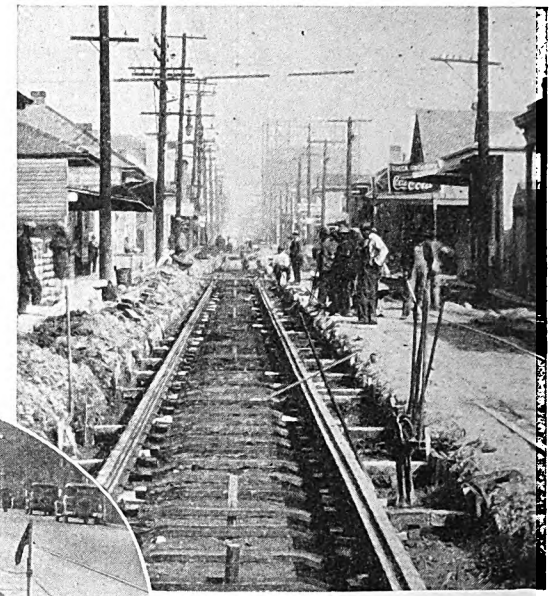
IT IS a far cry from the days of the rumbling stage coach bumping over cobblestone streets to the comfortable and speedy electric railway service of the present day. While the improvements which have been made in the design of the vehicle have attracted the largest amount of public attention, the advances made in the design and construction of roadway have been equally important in improving the quality of service. Today all forms of transportation are judged by the standards set up by the rubber-tired automobile and its attendant comfort. It is of the utmost importance, therefore, that the electric street car be provided with the smoothest and best type of roadbed that engineering skill can produce. To meet this need, numerous changes have been made in design and construction during recent years.

Development of improved rails has been one of the primary factors in the improvement of track construction. Very early in the growth of our cities it became apparent that some more adequate form of public transportation was needed than could be supplied by free-wheeled vehicles. The first street railway was built in New York in 1832 and others the following decade. Boston began the construction of horse car lines in 1856, Philadelphia in 1857 and New Orleans in 1861 and other cities soon after. These were followed by cable lines, the first being built in San Francisco in 1873. Electricity began to be adopted as a source of motive power about 1888. By the time street railways came into general use, the tee rail had been developed as the type most suitable for

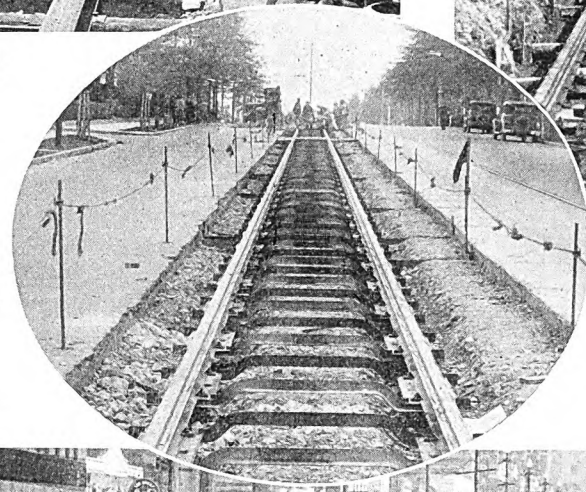
Digitized by Google



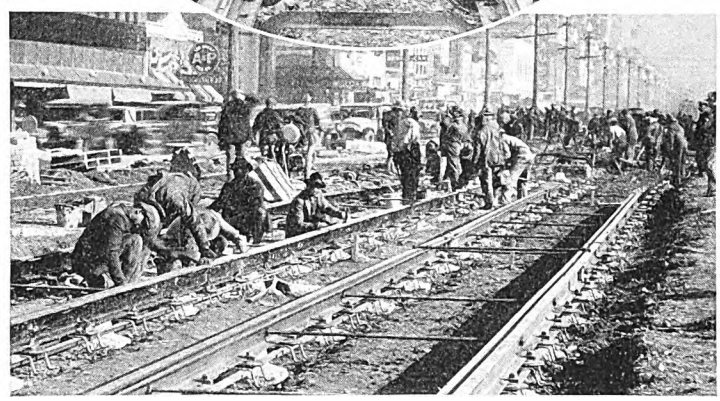
Grooved girder rail on wood ties is widely used in track construction



Combination steel and wood ties are used by numerous railways



A recent development in track construction is the use of bent steel ties



Experimental track built on rail seats without ties

steam railroads. At that period, however, the rails were all of light section, probably not over 4 in. high. This was found unsuitable for paved streets where deep block pavements were generally used, and the so-called tram rail was developed with a greater height and a horizontal lip to accommodate wagon wheels.

With the coming of the cable car and the electric car, speeds were increased as well as the frequency of service. This made it undesirable for free-wheeled vehicles to use the car tracks. At the same time smoother pavements were coming into extensive use so that there was not the same necessity for vehicles to follow the car tracks that had existed in the early days. The next development after the tram girder rail was a grooved type of rail known as the "Trilby" because the head portion of the rail when inverted resembled somewhat the Trilby type of lady's shoe then in vogue. The Trilby type of groove has since been modified to a groove which gives a better clearance for wheel flanges.

While there are a number of different grooved girder sections being rolled today, the one most commonly used is that adopted several years ago by the American Electric Railway Engineering Association as standard. This is made in sections either 7 in. or 9 in. deep. With the increasing use of concrete paving, however, the use of a tee section has regained a considerable measure of popularity. Several types of plain girder or tee rails have been adopted as standard by the A.E.R.E.A. There is also available a rail, first rolled for the Cleveland Railway, which is non-symmetrical in gage, the backside of the head being sloped in a manner similar to the head of the girder grooved rails so as to make a better job in paved streets.

In general there has been a trend toward the use of heavier rail. Heavy rail gives track a longer life not only because there is more metal to resist wear but because it spreads out the loads and due to its anvil-like action absorbs the shocks, thus protecting the balance of the track structure as well as the surrounding pavement.

The increasing of wheel loads, car speeds, volume of traffic and also heavy motor trucks has resulted in the building of more substantial track foundations. While wood ties continue to be used more extensively than any other type, steel ties and combination designs have many adherents. Many companies have also adopted concrete in the track foundation, especially where steel or combination ties are used. To obtain greater density and closer union between the concrete, ties and rails, a number of railways have adopted the practice of vibrating the concrete thoroughly before it sets. This is not a new idea but new machinery for doing the vibrating has recently been developed.

One feature of track construction that has probably caused more concern than any other is the method of joining rails together. In the old days the street railways followed the steam railroad practice of using fish plates,

Digitized by Google

and the various modifications including base plates and so-called continuous plates. However, on account of the difficulty in getting at joints buried in street paving, the troubles of the street maintenance-of-way man were intensified over that of his steam railroad brother when it came to maintaining joints. While the paving around street railway tracks is the source of a great deal of annoyance and expense, it does make feasible the practice of welding of rail joints. Thus we now have indefinite lengths of track, welded solidly so that it is, in effect, one continuous rail. The paving not only tends

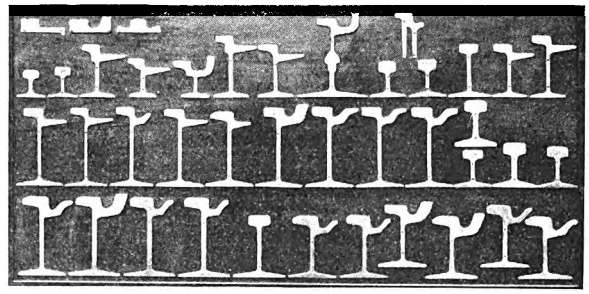
Digitized by Google

to keep down the extreme changes in temperature but confines the rail in such a way that it cannot buckle out of line and the stresses set up in the rails due to temperature changes are under the elastic limit of the rail steel.

The first method of welding rails together was by means of cast iron binding. There was, however, little actual weld in this case, the iron binding acting more through its gripping effect than through any actual fusion with the rail. Nevertheless, these cast-iron welds were remarkably successful. These gave way to the electric bar weld, the Thermit weld, the electric butt weld and the electric seam weld. Practically all the street railway track that is laid today is welded by one or the other of these processes, all of them being efficient but each having its own advocates and special applications. The welding of joints has prolonged the life of rails so that they can be used until worn down throughout their length instead of being scrapped when worn out at the joints.

In addition to joint welding, extensive use has been made of arc welding for building up worn spots in track. This welding can be done at a nominal cost and it has resulted in the saving of large sums of money.

Many improvements have been made in recent years in the design of special trackwork. When street railways first came into use, it was soon found that the switches used by steam railroads were not suitable for paved streets and what is known as the tongue switch was developed. This was a more or less crude affair at the start, as was also the other special trackwork. Frogs were either made by bolting together plain rails and cutting notches for the wheel flanges, or were made of cast iron. The sharp curves necessary in negotiating street corners were guarded with strap steel or specially rolled light guard sections secured to the running rails by bolts. These answered the purpose for a time but much difficulty was had in keeping these guards securely fastened and so there was developed a form of girder rail having a solid guard. This is a tremendous improvement over rail with a bolted-on type of guard. Great improvement has also been made in the method of making frogs. These are either made of high-grade alloy steel or of what is known as the iron-bound type with hard center inserts.



Development of rail as used in Baltimore from the earliest horse car days up to the present

We must bestir ourselves to hold our patronage by giving to our passengers the closest approximation we can to the comfort they enjoy in "riding on rubber." If we do not, we may expect to see them drifting away in greater numbers. All the time and efforts of the way engineer have been directed toward developing a type of track that will accomplish this and at the same time will give maximum length of service at minimum cost.

PROMINENT among the transportation facilities which have contributed to the development of many of our modern American cities is the suburban service offered by the main line railroads. Begun within a comparatively few years after the steam locomotive had been invented and the railroad had become a reality as a means of travel, suburban service has been developed more and more intensively, until today it stands in a distinctive class as one of the essential transportation facilities of the large community.

At the outset, the use of the available facilities of the steam railroads for commuter traffic seemed logical, both to the residents of the cities and to the managements of the roads themselves. Nearly every system entering a city of any size, particularly where a terminal was located, had obtained a choice site for a passenger station. In the days of railroad expansion it was considered essential to locate such a station as near as practicable to the center of business activities. At a time when freight traffic was comparatively light, little difficulty was experienced in scheduling passenger trains at convenient hours to serve the needs of executives and office and factory workers who desired to live along the line of the road. Since it was considered that the tracks and other facilities would have to be provided anyhow in order to handle through passengers and freight, it was only natural that reduced rates were offered to induce regular riders to use the suburban service which could be given with relatively small additional investment. Monthly, quarterly and annual tickets have been sold at rates far lower than the regular one-way fares, sometimes as little as one cent a mile if all the rides on the tickets are used.

As a consequence of this policy, in many cities a large business has been built up that has become an essential part not only of the railroad system, but of the community. In some instances it has brought a profit to the railroads and in others it is questionable today whether the service is operated at a profit or at a loss. But in any event, the growth of the communities has been fostered by this activity of the railroads.

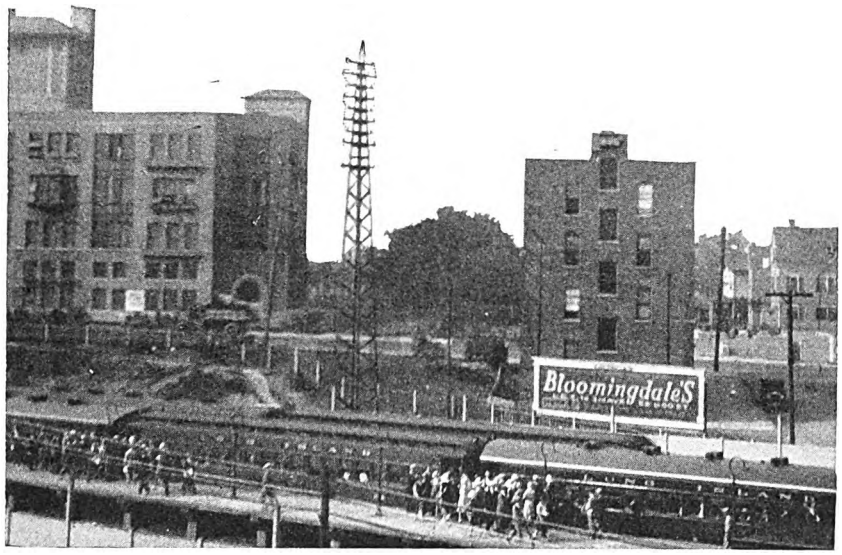
Generally speaking, suburban railroad service antedated the street railway, and was operated for many years before there was a thought of the use of electricity as a motive power. At first, the ordinary passenger coaches and locomotives were employed, but later some of the railroads developed locomotives which were able to produce higher acceleration rates and coaches which were particularly fitted to the needs of commutation service.

Under conditions of a generation ago, with no other

Digitized by Google

form of rapid transit available, the suburban service of the steam railroads furnished the only means through which the worker in a large community could live very far away from his business. With convenient terminals, it was quite possible for workers to spend a comparatively small amount of time in travel and reach points offering the advantages of country or suburban life. While the cost of transportation to the individual was not negligible it was not so high but that a considerable class of people found it possible to build homes at distances of 5 to 20 miles from the congested area. Naturally it was the more substantial element of a city that did this. As a result, the steam railroad has always had a high class clientele for its suburban business.

While the advent of electricity opened up many new possibilities for railroad suburban service, comparatively few systems adopted the new motive power at once. Those that did so were forced to it by public opinion or by legislative enactment. Even today a number of railroads are continuing steam service for this class of traffic with a considerable measure of success. The most progressive ones, however, have electrified in order to cope with the demands for rapid, clean and frequent service.



Woodside, one of the principal junction points on the Long Island Railroad, uses flush platforms

It is well to look into the possibilities of railroad suburban service as compared with those of rapid transit lines of the ordinary type. Naturally, speed is one of the prime essentials of suburban roads of either type. As to convenience, in some respects the rapid transit line probably has the better of it, since it does not need a single terminal in the heart of the city, but can operate through the entire length of the business district with stations at many convenient points. Against this, the main line railroad offers the advantages of comfort and a time-table which may be adhered to rigidly. As a rule, seats are provided for all passengers and many facilities are offered for the comfort of passengers. such as wider cars with cross seats, better upholstering, better lighting and ventilation, and smoking compartments, which are lacking in the more intensive rapid transit service. The fares being materially higher, undoubtedly the best class of travel is attracted to the suburban railroad, and this makes it necessary to do many things to keep the good will of the riding public.

Granted that railroad rights-of-way and facilities are available, it is much more logical to develop them for suburban service than to build competitive rapid transit lines, particularly subways. Accordingly, if a railroad already serves the territory it would appear much better and decidedly cheaper to electrify it and if necessary to construct short sections of subway in the business districts to provide for the distribution of passengers. This plan has been adopted in the electrification of the Pennsylvania Railroad in and about Philadelphia. Suburban trains will be diverted to a subway reaching the central district.

Suburban service has been of much benefit to Philadelphia. When the Pennsylvania electrified its main line a number of years ago, it opened up a territory for some 20 miles to the west of Philadelphia for commuters working in the city. This section has grown remarkably. Following closely on the conversion of this route, the Chestnut Hill branch was electrified, with a quite similar development of the territory served. The line to Wilmington was equipped about two years ago and is at present undergoing an increase of business. With the complete electrification of the Pennsylvania system between New York and Washington, suburban service will be given electrically as far as Trenton, and further growth of the communities along the line is anticipated. Electrification of the suburban lines of the Reading Railroad, which is now taking place, will put this system on a par with the Pennsylvania as a means of serving suburban residents in and about Philadelphia. In all these installations the exclusive suburban character of travel has been retained, so that there is no direct competition with the city-owned subways and elevated lines.

Suburban trains are operated successfully in several places on the Pacific coast by the Southern Pacific System and its affiliated lines. Views of the Alameda-Oakland lines appear on page 370.

Another possibility for the utilization of existing facilities for intensive service is to connect them with existing rapid transit lines for distribution of passengers in the business district. This has been urged many times. There are, however, comparatively few instances where the plan has been worked out. The most notable of them is the Ashmont extension of the Boston Elevated Railway's Cambridge-Dorchester subway. This route, with the surface trolley line extension to Mattapan, is nearly all on the right-of-way of the New York, New Haven & Hartford Railroad. The route has been equipped for rapid transit service at a cost much less than would have been necessary to build a competing subway. The capacity has been increased far beyond anything possible with steam traction, or even electrification of this one line as a part of the railroad service. It must be remembered, however, that in developing the line in this manner its character has been changed completely, and true rapid transit service is now being furnished instead of suburban commuter service. Steam railroad facilities are also to be used for rapid transit purposes in Cleveland. There several railroad lines are being electrified to form a rapid transit system entirely apart from the surface car system.

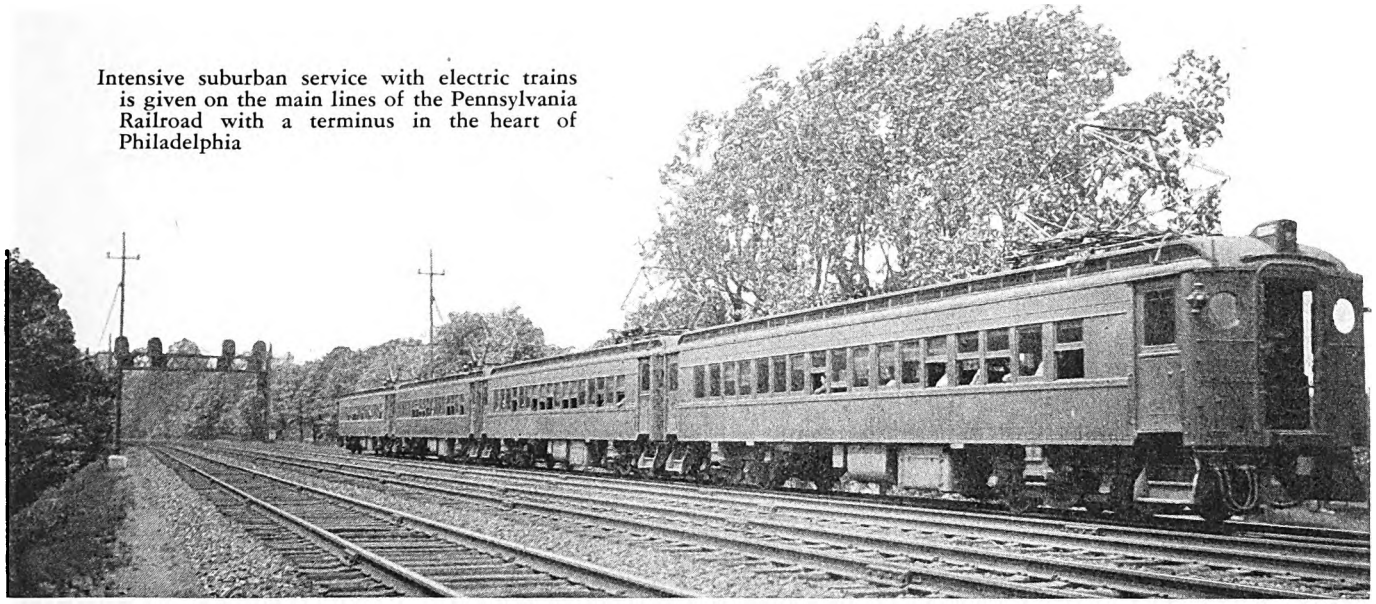
Digitized by Google

As a community builds up, naturally it becomes impossible to continue giving the same class of suburban service as was possible with low concentration of population and small amounts of traffic. As the demand grows, the congestion increases. Trains must be made longer and headways shortened until the service automatically approaches that given by rapid transit lines. This is what has occurred on the Long Island Railroad, serving principally the Borough of Queens in New York City. The Long Island Railroad has been faced with the necessity of providing what is virtually rapid transit service to the detriment of the riders who desire to travel to suburban points outside the city.

Under present-day conditions successful suburban service demands electric operation. The traffic densities are almost invariably too great to permit of satisfactory service with steam locomotives. Use of multiple-unit trains will increase the capacity of a stub terminal from 20 to 30 per cent, while with a through terminal or a loop station the increase in capacity may be even greater. With multiple-unit trains many of the problems involved in locomotive operation are entirely absent. Maximum acceleration can be obtained along with reasonably high speeds so that running times can be shortened materially. With electric heating and lighting of the cars, there is no necessity for frequent trips to a terminal or roundhouse, and the cars can be operated with little or no attention, save for periodic cleaning and inspection. Absence of smoke and dirt also have been popular.

As to the best type of equipment for suburban service, there is comparatively little diversity of opinion. Most of the roads use coaches of the ordinary steam railroad type, all or a portion being equipped with electric motors and control, the others being used as trailers. In a few instances, notably the Illinois Central Railroad, cars of a distinctive type have been developed for suburban service. All the cars have been designed for use with flush station platforms. These are desirable, as they save several seconds at each stop and make it easier for passengers to board and alight. On nearly all of the other railroads giving suburban service there are low station platforms, only a few inches above the rail level. On the Long Island Railroad a considerable number of the stations have flush platforms, while others have low platforms. This necessitates the use of trap doors which must be raised by hand at stations with low platforms.

A distinctive feature of railroad suburban service that has contributed much to its popularity as compared with rapid transit is the adoption of time-tables of the steam railroad type which make use of individual combinations of station stops for each trip. Trains may be run local for the entire distance, express for the entire distance, or there may be a combination of the two types of service on any train. A careful traffic analysis is made and the schedule is adapted to the requirements for that particular trip. If the headways are greater than the minimum it is thus possible to give a superior service, even though only a single track is available in each direction. This is distinctly contrary to the principles of rapid transit, where all trains of one class stop at certain designated stations, locals stopping at all local stations and expresses stopping at express stations only. As traffic density increases, however, it becomes more and more difficult for a suburban railroad to give more than a single class of service on one track and, as stated elsewhere, standard rapid transit operation is approached.



Intensive suburban service with electric trains is given on the main lines of the Pennsylvania Railroad with a terminus in the heart of Philadelphia

One element of cost that has a great deal to do with the difference in operation between trunk line railroad suburban service and rapid transit is the method of payment for labor. Rapid transit trainmen are almost always employed on an hourly basis, while trainmen in railroad service are paid on a mileage basis. This makes it possible for the railroads to schedule trains with much more flexibility. Coupled with greater lengths of route, favorable time-tables can be made up with minimum labor cost and with little waste service during the non-rush hours.

The length of the commuting zone varies with the type of community and the service furnished. Some roads have catered to this class of service in one or more communities and accordingly have built up larger or smaller districts, suburban in character and tributary to the central district. Striking differences have existed on this account in comparable territories. For instance, the writer knows of one example where two parallel trunk line railroads pass through quite similar territories. One of them gave an intensified local passenger service and as a result developed suburban towns on an average of one to two miles apart for a distance of 40 miles, while the other one had practically no suburban development along its line.

"NET" can come from two sources—increased earnings or decreased expenses. Improvements in design can bring about both. For some time past we have been attempting to attract riders through improved appearance, riding comfort and speed.

The electric coach attracts riding not alone because of its appearance and comfort, but largely because the rider is impressed with a sense of speed. A modern street car on a good track furnishes a comfortable ride, but a rubber-tired vehicle with its flexibility, quietness and light weight, permitting rapid acceleration, very nearly approaches the ideal mass transportation unit for the average city.

The co-operative installation or use of ornamental poles for the support of overhead structures occasions a favorable public reaction

Increased Power Department Responsibility Demands PROPER EQUIPMENT

TODAY the activities of the power department of the average modern street railway extend far beyond the responsibility of supplying, through a system of distribution and contact structures, a continuous and economical source of propulsion energy for the movement of cars. The leaders in the industry acknowledge this and, therefore, no longer feel that the scope of power development responsibility ends with the production and distribution of electrical energy, but that it has a real place and constitutes an important part in the general scheme of building up and maintaining friendly relations with patrons of the company and the public at large.

The question is then asked: What are the conditions or qualifications necessary to enable the power department to fulfill best its place according to the modern conception, wherein the sphere of departmental responsibility has been increased?

Primarily these may be classed as follows: continuity of power supply; modern equipment and practices properly maintained; a company policy regarding the public in general, wherein the department, as a unit of the entire company, recognizes and fulfills its responsibility to the public as well as to the company through a more or less definitely prescribed company channel.

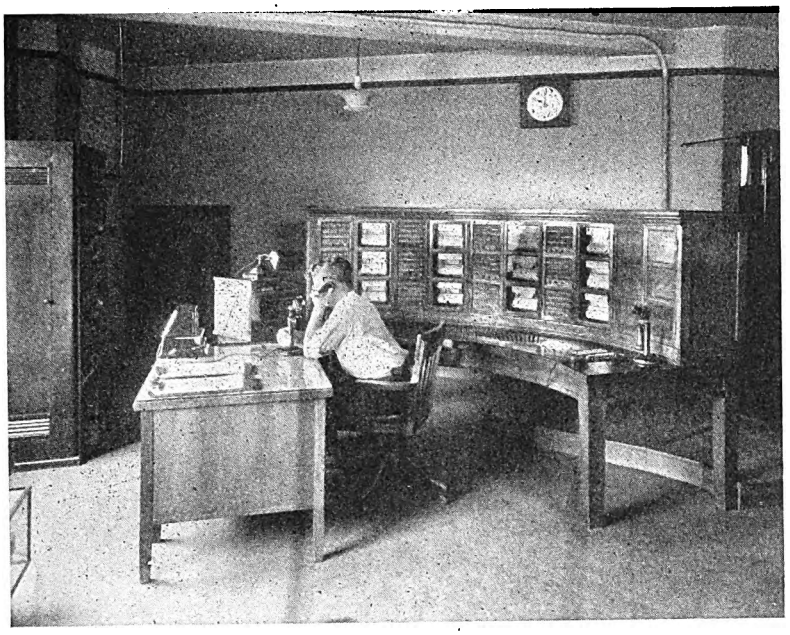
In perusing the three major qualifications and realizing that the one incentive behind the whole structure is to build up a business by demonstrating the ability and desire to serve, one cannot but realize that accomplishment of the desired end is at least impracticable, if not impossible, should any one of the three qualifications be absent.

Dependable service cannot be rendered if the source of power frequently fails. Continuity of power supply cannot be maintained utilizing antiquated equipment or antiquated operating and maintenance methods. Harmonious public relations cannot be maintained if the foregoing qualifications are not fulfilled. On the other hand, the most modern methods and equipment rendering 100 per cent service cannot discount the ill effects of poor public relations or an antagonistic local governmental body. Therefore, one or even two of the qualifications without the third will be of no avail. The triad must exist. In this article it is the intention of the author to discuss briefly only one of these qualifications; namely, modern equipment and practices.

The electric railway industry has witnessed no development quite so revolutionary and far-reaching as the perfection and adoption of the automatic substation. During the sixteen years since the first station of this type was placed into operation, the cost of power delivered to the car has been decreased, accompanied by increased reliability of service and greater freedom from labor

Digitized by Google

troubles on systems where the automatic plant has been installed to any extent. In interurban service this type of plant, even in its simplest form, has demonstrated its ability to render satisfactory performance at a material decrease in operating costs when compared with operating costs of the former manually operated plants. In metropolitan service a full complement of automatic equipment, operated in conjunction with remote and supervisory control and a properly designed distribution system, establishes a power system which, because of its many power supply points located advantageously about the entire system and its extreme flexibility, guarantees a continuity of power supply to the system that can be accomplished in no other way and at a lower cost of power at the car than was possible with former methods of distribution.



Remote and supervisory control, utilizing various colored lamps for indicated condition of conversion and distribution system control equipment

The mercury arc rectifier has advanced to a position where, in certain types of service, definite advantages may be gained by its use. The efficiency characteristic of this device at fractional loads causes it to be particularly well adapted when, for a greater percentage of the time, the nature of the load is such that the equipment is but partially loaded. The rectifier, in its simplest form, is less complicated and less costly to install than rotating equipment installed for automatic operation. The cost of maintenance should likewise be lower. However, when considering major sources of power in metropolitan service, additional features which must be considered in many instances invalidate the advantages of the rectifier and cause rotating equipment to be selected. Paramount among these features is the fact that conversion equipment in this class of service is generally operated at or near capacity as long as it remains in service, particularly if automatic control is employed and the stations and distribution system are under remote and supervisory control. Furthermore, to protect fully the operation of the rectifier in major plants, duplication of the water cooling system, employing some form of recirculating system in addition to the normal supply of water from the city mains, would be necessary. Likewise, serious telephone interference is very apt to be encountered when rectifier equipment is operated in metropolitan areas. Prevention of such a condition would necessitate the installation of additional apparatus not required with rotating equipment.

With the advent of the automatic substation has come not only an entirely new type of housing structure, but

likewise new ideas, aesthetic in their nature, regarding the surroundings of the building. The substation building no longer takes the form of conventional factory structure for in some instances where stations have been located in suburban residential areas it would be difficult for the uninformed to distinguish the substation building from neighboring residences. By these means, the engineer has been able to realize upon the advantages offered by the automatic plant and obtain a source of power supply in territories where heretofore it was necessary to absorb the heavy power losses and annual charges due to long distribution cable or suffer low operating voltage with its adverse effect upon car schedules.

In applying the automatic substation, particularly to the metropolitan field, the necessary feeder calculations are considerably more extensive and exacting than was generally the case with the larger capacity manually operated plants. The smaller capacity of the automatic plant and the relatively confined area which it is intended to feed makes it necessary to work within closer limits than formerly. The problem of reserve capacity is no longer solved by installing spare equipment in each substation.

Removing old and stringing of new trolley wire in one operation

The close proximity of the power sources permits of a more economical method and insures greater continuity of power supply to the system as a whole. Due to this new arrangement, the distribution system is utilized to make available the capacity of the entire system which may not be in use at any particular moment. To accomplish this result a close adjustment of the ohmic resistance of the feeder system between stations is necessary so as not to unbalance the load between stations.

The supervision of a number of automatic plants in metropolitan service, particularly where they constitute major sources of power, is an essential factor in obtaining the maximum economy and the highest guarantee for continuity of service. Superimposing some form of remote and supervisory control upon the automatic features of the conversion equipment and the outgoing direct current distribution control system, by means of which a dispatcher may at all times be fully acquainted with conditions on the system and in which he has at his disposal means to change conditions instantly whether due to routine operation or emergencies, constitutes without question the greatest insurance for efficient operation and a continuous supply of energy to the cars.

Simultaneously with the development of the automatic substation, the remote and supervisory control system and the new conception of the distribution system, which constitutes one of the greatest contributions the engineer has made to the industry, great strides have been made elsewhere within his jurisdiction. The great improvement in performance of overhead contact and distribution systems, in many instances at a reduced cost per mile, is certainly worthy of comment. Year by year due to intensive study and the research work of the railways and the manufacturers new low records are being established for trolley wire breaks. The stringing of trolley using the dynamometer method, rigid inspection on a car mileage basis rather than at definite periods regardless of car passages, dependable reports and the schooling of employees are chiefly responsible for this marked improvement. The industry is indebted to the several A.E.R.E.A. Power Committees which have made studies and prepared reports upon this and allied subjects. These reports have not only created influence toward standardization, making possible the procuring of better materials, but they also have been the means of placing before the individual engineer a cross section of what the industry as a whole is accomplishing. As a result they have given him new insight and an incentive for additional work.

Since one of the prime factors in the delivery of a continuous supply of power to the car is the contact system, it behooves the engineer to eliminate every trolley break possible from whatever cause. In this connection it has been noted, in perusing the reports of various railways, that there is more or less of a universal increase in the number of trolley breaks under the so-called uncontrollable classifications. These are due to pull-downs or burn-downs by railway equipment, in most instances improperly operated, or by objects of unusual dimensions being transported through the city streets.

Much favorable public reaction may be occasioned by the co-operative installation or use of some form of ornamental pole for the support of overhead structures, particularly if the channels are available whereby the public can be made to realize that the railway, by such acts, is interested in contributing to the civic improvement of the community. There have been several installations within the past two years where railway poles, street lighting standards and traffic signal standards or poles have been replaced by the use of one structure resulting in a greatly improved appearance of the thoroughfares.

Profitable results may be obtained by instigating a survey of the distribution system to ascertain its efficiency. This investigation, which involves the distribution plant from the power sources to the cars and includes both positive and negative sides of the circuit, is, of course, considerably simplified if the cars are equipped with power measuring devices. Quite aside from the possibility of advantageous readjustment of parts of the distribution system, based upon the results of such a survey, it will indicate the difference between the total amount of power drawn from the bus bars of the system power sources and that actually used in the production of revenue car-miles. It is safe to say that the engineer who has not taken the occasion to make such a survey will be astonished at the amount of energy used on his system for miscellaneous purposes.

One important item of electric railway maintenance, which is too often neglected, is rail joint conductivity and the method of determining electrical resistance of rail joints. The electrical conductivity of the track joints not only has an important bearing upon the efficiency of the distribution system but also involves the relationship of the railway with other public utility companies utilizing the city streets as well as the individual property owners and patrons of the company.

The foregoing includes but a few of the important factors by which an economical and continuous supply of energy may be assured and where other functions of the power department may be conducted in such a manner that the railway and the public are best served. These factors, in the majority of cases, constitute two of the three conditions or requirements mentioned previously.

The third factor must be accomplished through the cooperative effort of the entire personnel. Employees in contact with the public must be schooled in order that proper conduct will be assured. Proper means also must be established, maintained and controlled, whereby the public is kept constantly advised of the company's steps to insure safe, speedy and dependable transportation at lowest possible cost.

MODERN MACHINERY

A Sound Investment for

Better Maintenance

By

E. J. JONAS

Superintendent of Equipment
Cincinnati Street Railway
Cincinnati, Ohio

EXPERIENCE has proved that most car equipment of the conventional design can be made reliable and reasonably quiet in operation by efficient inspection and maintenance standards, the price of which is good tools plus eternal vigilance. With these two allies many electric railway properties have made real progress in keeping their cars in better condition at a lower cost. Great reductions in number of pull-ins and increases in mileage without mechanical difficulties serve as the tangible proofs for many systems of this program.

Well-arranged shops and carhouses, furnished with modern machinery and equipment, have played an extremely important part in improving the quality of work and, more particularly, in reducing costs. Adequate maintenance facilities and the provision of the proper machines for doing the many types of work are being considered essential by more and more companies. They realize the opportunities for savings in labor and equipment and that the resulting economy makes the additional or improved facilities a good investment.

A little more than two years ago the Cincinnati Street Railway completed its Winton Shop and transferred its operations from the old Chester Park Shops. Much thought was given to obtaining the best possible design and location of the building proper. In line with an efficient building layout, the company provided all the

Digitized by Google

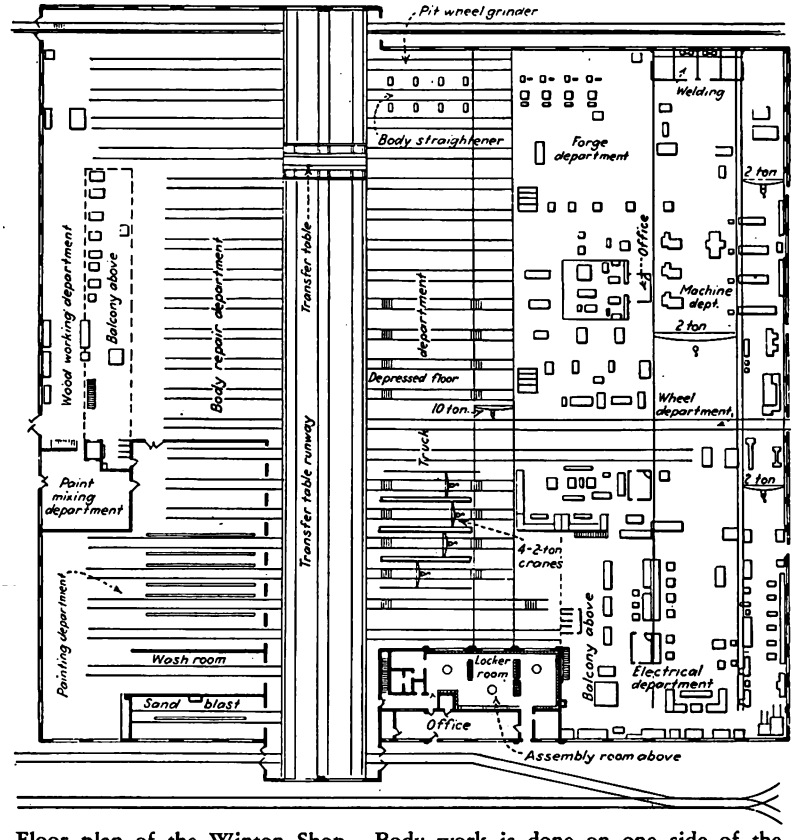
necessary modern machines and equipment for the efficient overhauling and maintenance of its rolling stock.

The steady increase in car-miles per disabled car from an average of 4,500 in December, 1927, to 20,000 in September, 1929, and the gradual decline in maintenance cost per car-mile, show a justification for the investment made in these modern facilities for street car upkeep. Many of the practices in maintenance work made possible by the new shop and its equipment are relatively insignificant in themselves as compared to the whole; many of these accomplishments are more the result of providing workmen with facilities and surroundings that encourage initiative and individual effort rather than the installation of labor-saving machinery.

Idle Workmen or Idle Machines?

In selecting new shop equipment it is advisable to obtain the best possible machine for the work to be performed, bearing in mind that an idle tool is unprofitable. In cases when such a tool will only be used occasionally, it is best to purchase the least expensive. On the other hand, an idle workman is more expensive than an idle machine; therefore, adequate equipment must be available in order that man-hours will not be lost on this account.

In the electrical department of the new Winton Shop the equipment includes five welding sets, two automatic wheel welding heads, two armature baking ovens, an electrically heated cleaning tank, a waste-treating plant and nine grinders of various types. Metal-working machines include ten lathes, a 400-ton car-wheel press, numerous grinders and drills, and other useful equipment. A very complete array of machines is provided in the woodworking department. Other equipment of special interest includes two cleaning ovens, a car-body straightener, an air-valve test bench, a special sand blast, a car spray hood, a combination transfer table and car hoist and a telescoping air jack. In an accompanying table all of the important machines and tools are listed.

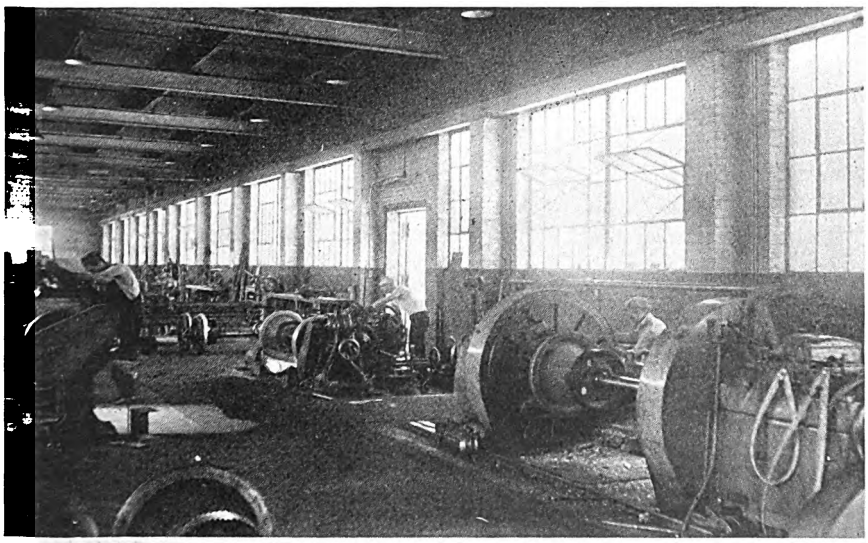


Floor plan of the Winton Shop. Body work is done on one side of the transfer table runway and all truck and electrical work on the other side

A slight modification of the principle of designing a shop so that each track will hold but one car was made to bring about a more harmonious floor plan. In the erecting department four of the tracks are long enough to accommodate two cars. This does not interfere with the general scheme, however, as cars that must remain in the shop for a longer period are placed at the far ends.

The principle of keeping all body work on one side and all truck and electrical work on the other side was recognized in the floor plan. To facilitate the placing of the car body in one department and the trucks in another at the start of the overhaul it was decided to place a car hoist directly on the transfer table, doing away with the necessity of equipping each erecting shop track with an individual hoist. This arrangement has since proved to be ideal for this shop, no confusion or congestion resulting from movement off or on the transfer table. It is provided with a power cable reel for moving cars and trucks with motors and a motor-driven winch for moving equipment not having motive power. The car hoist consists of two 15,000-lb. overhead hoists, each having two drums on one shaft with hooks at the lower ends of cables that permit raising car bodies to a height of 6 ft. This height permits a thorough and final inspection of the body, brake rigging, side and center bearings, and other parts.

No live trolley wires are suspended over repair tracks, since the move-



Section of the wheel department with its array of modern machinery for maintaining and reclaiming wheels

Digitized by Google

ments are very short and can be accomplished by means of cable leads or the power winch and rope.

In locating the various tools and machinery, care was taken to place them so that the parts being overhauled would be moved a minimum distance. The present output of eight overhauled cars per week of 45 working hours is not an adequate indication of the capacity of this shop, since much of the work being done at present consists of rebuilding rather than overhauling.

Provisions for Handling Materials and Parts

Physical exertion is reduced to a minimum in the handling of parts and supplies by means of numerous jib cranes and an electric industrial truck with elevating platform of the high lift type. The shop also is equipped with one 10-ton and nine 2-ton floor-operated traveling cranes.

When motors are removed from trucks they are placed on platforms that permit the lift truck to pick them up without further handling, and are delivered to the motor repair section. Mounted wheels are transported in like manner. Air compressors, controllers and resistors as well as all supplies from the storeroom, are also handled by this truck.

Incoming motors are placed near the cleaning tank where housings and armatures are removed. Housings are placed in the cleaning tank, while armatures are passed down to the winding section for dipping and baking. They are then taken to the bending lathe, and finally are removed to the armature bench near the vertical boring mill and bearing press. By this time cleaned housings have also arrived at this point. The bearings are then checked and new bearings bored to the correct fit if new ones are needed. All armatures and axle bearing housings are kept with their respective motor frames when being reassembled. After motors

NEWS *of the Industry*

LATE NEWS

Alliance, Ohio—Approximately $40,000 is being expended by the Stark Electric Railroad this summer for rehabilitation. The company operates between Canton and Salem, a distance of 30 miles. Fifteen thousand new ties are being placed and several grade crossings are being rebuilt.

✦

Philadelphia, Pa.—The Philadelphia Rapid Transit Company has purchased the Hartel Cab Company, operators of about 25 cabs from the Sixty-ninth Street Terminal here and in Lansdowne. Yellow cabs will replace those formerly owned by the Hartel Company.

✦

Chicago, Ill.—Union employees of the Chicago Surface Lines have signed a new wage and working agreement with the company. The terms include renewal of the wage scale which has been in effect for the last three years. The renewal is for one year from May 31.

✦

Lawrence, Mass. — The Eastern Massachusetts Street Railway made its fourth installation of the weekly pass at Lawrence on May 18. The pass sells for $1.25 against a cash fare of 10 cents and ticket rates of fourteen for $1, and Belt Line rate of six for 50 cents. The Brockton division added a pass Nov. 3, 1929; Lowell, Dec. 29, 1929, and Haverhill, Jan. 24, 1930.

✦

Seattle, Wash. — Agitation for construction of a loop to replace the wye at the north end of the Phinney-Greenwood Municipal car line, North 85th Street and Greenwood Avenue, is being revived. Building of the loop would require the purchase of private property for right-of-way as Phinney Avenue is not cut through in this area. The purchase and the loop construction would cost about $30,000.

✦

St. Louis, Mo.—The General Taxicab Company ceased operations at 4:30 p.m. on June 9 because it was unable to meet the demands of the Chauffeurs Union for payment in full of wages due the 125 chauffeurs normally employed, or post a cash guarantee that the wages would be paid. The company has been holding back five days wages of employees in making up its payrolls. It has been named defendant in bankruptcy proceedings. Forty-four of the company's 66 cabs were in operation on June 9.

✦

Los Angeles, Cal.—The Pacific Electric Railway has applied to the Railroad Commission for authority to issue two notes of the face amount of $311,846 each, to Motor Transit Terminal Corporation, in part payment of the purchase of capital stock of Motor Transit Company, operating an extensive auto stage service in southern California. The notes are to be dated Jan. 1, 1930, and one is to be payable July 1, 1931, and the other on Dec. 31, 1931.

Auto Does Not Justify Its Use of St. Louis Streets

Merchants Misguided About the Value to Them of Customers Who Come to Stores in Their Own Cars—Five Times as Many Carried by Street Car as by Auto

TO DETERMINE accurately the character of traffic in the business district of St. Louis, Mo., the St. Louis Public Service Company on May 26 sent 170 checkers into the district bounded by Twelfth Boulevard, Market Street, Third Street and Washington Avenue, to note the kinds of traffic in that section and the volume of such traffic.

Among other things the company wanted to know what part private automobiles play in transportation and whether parked automobiles carry a sufficient number of persons to justify their private-garage use of much-needed street space on the badly congested downtown thoroughfares.

The checkers found that 45,961 automobiles entered the district during twelve hours and carried 72,342 persons, an average of only 1.58 persons per automobile, including the driver. It was found also that 14,693 of these automobiles parked at the curb during some time of the day. Thus it was found that the parking of these private automobiles in the 56 square blocks comprising the congested area accommodates only 23,222 persons. That number was only 10 per cent of the persons who entered the district during the twelve-hour period under observation. In short, 10 per cent of the persons entering the district monopolized about one-third of the downtown street space for the storage of their automobiles. The average parking time of automobiles ranged from 45 minutes on Sixth Street to 1 hour and 40 minutes on Market Street.

In the twelve-hour period, 216,350 persons entered the downtown district and of these the street cars and buses carried 129,819 or 60 per cent. During the rush hours 7 a.m. to 9 a.m., the street cars and buses carried 73.5 per cent of all and the street cars alone 65 per cent. The average street car load was 28.5 persons. The buses carried 15,277 persons into the district and with 693 buses entering the average was 22 persons per bus. Service cars, or jitneys carried 6,528 persons in 1,629 cars or only four persons per vehicle.

The 1,221 street cars and buses entering the district carried four times as many people as the 14,532 private automobiles. The elimination of all parking in the downtown district would save five minutes to street car riders in getting into and out of the congested district. Some downtown business men have been reluctant to advocate the abolition of parking, even on very narrow streets. The traffic check made by the railway dispels the theory that parked automobiles are an aid to retail business downtown.

Checkers, who studied the customers of the city's four large department stores during the day, found the total in excess of 120,000 or about five times the total number carried into the district by all the private automobiles. Few persons who use the downtown streets for private garages are potential customers of the stores in the districts. Most of them are employees of various establishments.

Illumination a Feature

AS an added entertainment feature of the American Electric Railway Association Convention at San Francisco, the local committee of the National Electric Light Association will hold over from the convention of that association the special illumination features in the Civic Center so it will be available for display on Monday evening, June 23, following the A.E.R.A. banquet.

Engineers Report on Transit in Philadelphia

J. A. Emery, chairman, Milo R. Maltbie, W. K. Myers and S. M. Swaab, constituting the transit advisory committee to the general conference on the transit situation in Philadelphia, filed their report on May 24. The document covers 151 pages of typewritten text together with 71 tables. The report deals with the principal facts of the transit situation. The members of the committee do not recommend any specific plans for improvements, nor do they attempt to determine what is preferable, believing their action in this respect to follow the purport of the instructions under which they proceeded.

In the discussion of the various plans they illustrated the financial results under certain assumed conditions. They say that no one can predict what terms might be agreed upon between the city and other parties at interest under any one of these plans without knowing specifically the terms and conditions.

In their discussion they used the financial data reported by the Philadelphia Rapid Transit Company for the year 1929, but did not attempt to analyze, audit, or review the data as such criticism would involve among other things the determination of questions at issue in a judicial proceeding and were considered beyond the scope of the inquiry which the members were instructed to conduct. The members of the committee say that it is impossible at this time to make a satisfactory forecast of earnings of the property largely because of changing economic conditions.

Conway Interests Take Philadelphia & Western Railway

Thomas Conway, Jr., and his associates have assumed control of the Philadelphia & Western Railway and will actively direct the management. The company operates a high-speed suburban system running from the 69th Street Terminal, Philadelphia, to Strafford and Norristown, respectively, passing en route through Ardmore, Haverford, Bryn Mawr, Villa Nova, Radnor, and other communities.

For the purpose of insuring continuity of management and policies, the holders of a majority of the total number of outstanding shares of capital stock of Philadelphia & Western are depositing them under a voting trust agreement extending over a period of years under which Thomas Conway, Jr., William L. Butler, Alba B. Johnson, Edgar C. Felton and C. Jared Ingersoll are named as voting trustees. Mr. Conway has been elected chairman and Mr. Butler vice-chairman of the board. They will be the senior executive officers of the company. No changes in the operating personnel are contemplated. John L. Adams will remain as president, reporting to the chairman and the vice-chairman of the board. Mr. Johnson has been associated with the Conway interests in other electric railway properties.

The plan also contemplates that a large block of stock in the Philadelphia & Western will be acquired by the Conway interests.

In 1922, Mr. Conway and his associates took over the management of the Chicago, Aurora & Elgin Railroad, a high-speed suburban system serving the western suburbs of Chicago. During a period of approximately four years of operation of this property by the Conway interests, gross revenues from railway operation were increased 66 per cent, and net earnings, after operating expenses, maintenance and taxes, more than 150 per cent. In 1926, the control of this company was sold to the Insull interests.

Early in 1926 the Conway interests acquired control of the Cincinnati, Hamilton & Dayton Railway and since that time total operating revenues have been increased 22 per cent and net earnings more than 230 per cent. On Jan. 1, 1930, four other electric railway properties were acquired and the name of the company changed to Cincinnati & Lake Erie Railroad, now one of the largest interurban railway systems in the United States.

The Conway interests, through the Thomas Conway, Jr., Corporation, are the developers of Drexel Park, one of Philadelphia's most beautiful suburbs.

Segregation of Ohio Light and Railway Properties

Stockholders of the Pennsylvania-Ohio Power & Light Company, Northern Ohio Power & Light Company, the Ohio Edison Company, the Akron Steam Heating Company, and the London Light & Power Company, all operating in Ohio and owned by the Commonwealth & Southern Corporation, have been informed that the directors of these companies are of the opinion that to consolidate them, thus uniting the electric light, power and steam heating business into one company and to separate the transportation portion of their properties into subsidiary units, will result in increased efficiency and economy of operation and create an electric company with a greater diversity of consumer use than is now possessed by any one of the individual companies. Accordingly a new company will be formed to be known as the Ohio Edison Company, which will also acquire the physical assets of Ohio River Edison Company and the Ohio River Transmission Company, which companies own the power plant and transmission lines now leased to the Pennsylvania-Ohio Power & Light Company. It is also proposed to convey the transportation portion of the the property of these companies to three separate companies, retaining the consolidated company's equity in them through stock ownership.

Milwaukee Rate Case Under Way

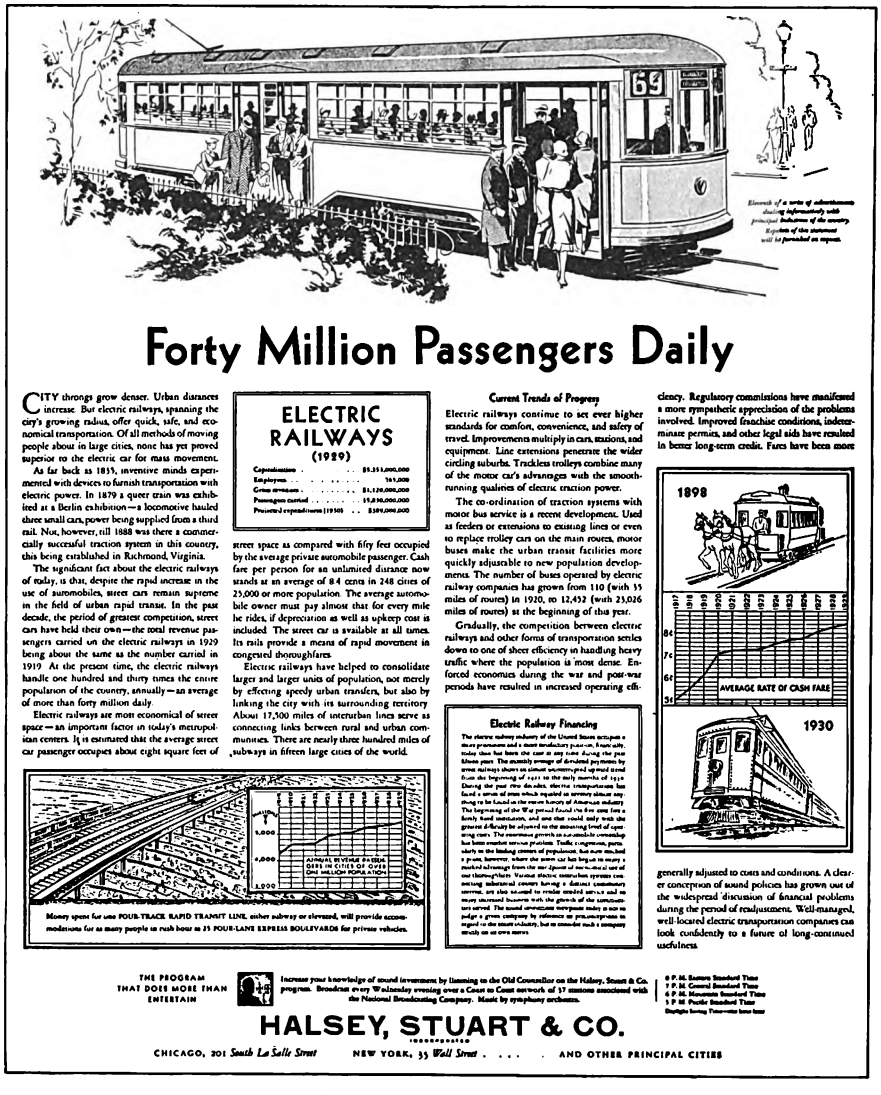
The suburbs of Milwaukee were authorized to intervene in the appeals of the city and the Milwaukee Electric Railway & Light Company from the Railroad Commission's recent street car rate order by Circuit Judge Zimmerman on June 9, at a hearing for preliminary motions in the case at Madison. Trial of the appeals was set for June 18.

Judge Zimmerman also granted the company's plea that its appeal and that of the city be consolidated for puropses of trial. City Attorney Niven said he would not oppose consolidation of the cases if it was understood that the cases were to be presented separately at the same trial.

Nine suburban communities were represented at the trial. The city and the company are appealing from the commission's order as inequitable. The commission, which will be defendant at the trial, was represented by the assistant attorney general at the first trial. The suburbs and other outlying districts, which stand to gain from the commission's order, are intervening to defend the order.

Effective Banker Co-operation

Co-operation from an unusual source in the campaign of the electric railway industry to impress the public with the importance and value of the electric railways is reflected in the accompanying advertisement which appeared over the signature of Halsey, Stuart & Company in the *United States Daily* on May 28, 1930. This advertisement is one of a series dealing informatively with the principal industries of the country. The purpose back of the advertisement was to have it serve as an effective reminder of the important place which the electric railways play in the present transportation system.



Display Ad Emphasizing Importance of the Electric Railways

LATE NEWS

(*Continued from Page 422*)

Cleveland, Ohio — The department store for which the Van Sweringen interests made provision in their Cleveland Union Terminal group will be occupied by the Higbee Company, in business 70 years. The store will be built at the intersection of Ontario Street and the south roadway of the Public Square, above the rapid transit tracks and terminal. Construction contracts are to be let immediately.

✦

Utica, N. Y.—Segregation of earnings of the various units of the New York State Railways as urged by holders of mortgage bonds covering the Syracuse and Rochester units and opposed by holders of bonds on the Utica lines, is under consideration by Judge Bryant of the United States Court.

✦

Tacoma, Wash. — Representatives of Titlow Beach and the far west end of the city have thus far failed to convince Tacoma Railway & Power Company officials that there is enough business out Sixth Avenue beyond Proctor Street to warrant the company putting in a bus service at regular city fares. Commissioner Davisson suggested that the company institute a 90-day trial of the bus line.

✦

Davenport, Iowa—Dissolution of the Tri-City Railway & Light Company of Davenport, Iowa; Rock Island and Moline, Ill., to simplify the financial structure of the United Light & Power Company will be voted upon June 19 at a special meeting of stockholders. Direct control will be placed with the United Light & Power Company by the elimination.

✦

San Francisco, Cal.—Officials of the Southern Pacific Company have announced that hereafter special permits will be issued to blind persons accompanied by "seeing eye" dogs giving them the right to use any of its trains carrying coaches, in club cars of Pullman trains, on the upper deck of ferry steamers and on electric trains.

✦

Concord, N. H. — Robert J. Dunn, who operates a bus company under the name of the Yellow Cab Company here, has been authorized to operate a line between Concord and London, N. H., via the Concord airport. At the Public Service Commission hearing on the matter, the petition was opposed by the Boston & Maine Transportation Company and the Concord Street Railway. The latter's rights are protected in the decision of the commission by a clause that forbids the Yellow Cab Company to take on passengers on any streets where the railway holds franchise rights.

✦

Nashville, Tenn. — Hiram A. Davis, superintendent of the railway department of the Nashville Railway & Light Company, is dead.

✦

New York, N. Y.—In a letter to President Hedley of the Interborough Rapid Transit Company, the Transit Commission has declined to hold a hearing on its proposal to issue $40,000,000 additional first and refunding bonds to finance purchase of additional cars ordered by the commission on April 30. The commission holds the company should amend the petition to conform with the commission's wishes.

✦

New York, N. Y.—More than 85 per cent of the replies received by the Interborough Rapid Transit Company in its poll of passengers on the Sixth Avenue "L" favor retaining this line until it is replaced by a subway on Sixth Avenue, according to a summary made public by the company. In answer to the question, "Do you want the Sixth Avenue 'L' kept in operation until the proposed city subway under Sixth Avenue is in operation?" the following replies have been tabulated: Yes, 12,136; no, 2,085.

✦

St. Louis, Mo.—The Missouri Public Service Commission has approved the plan for the St. Louis Public Service Company and the Peoples' Motor Bus Company to interchange transfers for the convenience of patrons of the St. Louis Municipal Opera, which opened a twelve-week season at the Open Air Theatre in Forest Park on May 30.

✦

New York, N. Y.—Supreme Court Justice Levy has granted the city's application for removal of Interborough Rapid Transit Company's elevated spur in East 34th Street. At present, one-car shuttle train, carrying an average of 140 passengers a day is operated over line.

✦

East St. Louis, Ill.—The City Council has adopted a resolution opposing the application of the East St. Louis Railway for a straight 10-cent fare for adults. Cash fares now are 10 cents but five tokens are sold for 40 cents.

✦

Louisville, Ky.—Director of Works Will has approved the application of the Louisville Railway to abandon the Brook and West Main line, the Bank Street line and the Jefferson Street line west of Seventh Street. Mr. Will has also approved the rerouting of the Portland Street line, the inauguration of a bus route in Portland and a rerouting of the Preston and Main Street line. The changes will be put into effect within 60 days.

✦

St. Augustine, Fla.—Authority has been granted the city of St. Augustine and the St. Augustine Company, controlled by the Florida Power & Light Company, for abandonment of the railway here in an order issued by the Railroad Commission. The line runs from just east on the Matanzas River bridge across Anastasia Island for a distance of 4.8 miles. The commission said its right was not "exclusive and complete," but that it would be for the best interest of the applicants and the public.

✦

St. Louis, Mo.—The St. Louis Public Service Company has been requested to substitute iron for wooden trolley poles from Olive Street between Twelfth Boulevard and Channing Avenue. A recent experiment of suspending trolley wires from the concrete light standards on Olive Street just west of Twelfth Boulevard indicated that these poles were not sufficiently strong to sustain the additional weight.

Brooklyn, N. Y.—The valuation basis to be used in fixing the price to be paid by New York City for elevated lines of the Brooklyn-Manhattan Transit Corporation continues to be one of the main stumbling blocks in the way of unifying the company's rapid transit lines with the city's new subway system, it developed at a conference of city and state transit officials.

✦

Milwaukee, Wis. — Latest appraisals of the estate of John I. Beggs, long president of the Milwaukee Electric Railway & Light Company, place its value at $54,800,000.

✦

Anderson, Ind.—Receivership proceedings of the Union Traction Company were advanced in Madison County Circuit Court on June 6 when Judge Carl F. Morrow entered a decree with an order to the receiver to sell all property of the company at auction here on July 2. Through deals made direct with bondholders, the Insull interests in the last year have a contract to buy more than 60 per cent of the outstanding bonds of the Union Traction system, and with these in their possession will be in an advantageous position as prospective purchasers.

✦

Chicago, Ill.—First prize in the electric railway posters and cards division competition of the Public Utilities Advertising Association was won by the Chicago Rapid Transit Company.

✦

Manchester, N. H.—The Manchester Street Railway, now being operated by the Public Service Company of New Hampshire, celebrated the 35th anniversary of the electrification of the road on June 8. Officials of the company and city government leaders rode on a new 44-passenger trolley over the route followed by the first car 35 years ago.

✦

New Haven, Conn.—Employees of the Connecticut Company have agreed to a renewal of the present wage scale for one year from June 1. Operators of cars and buses, shop workers and power house men are included. Recently the men, through their executive committee, asked for an increase and changed working conditions. Following conferences it was decided to vote again with the result that the former scale has been renewed.

✦

New York, N. Y. — Additional testimony has been furnished the Mayor's Taxicab Commission favoring a limit on the number of cabs and an increased fare, by Ernest H. Miller, president of the Parmelee Transportation Company, who urged the adoption of a uniform rate of 25 cents for the first quarter mile and 5 cents for each succeeding quarter. He also urged the number of cabs be limited to 15,000.

✦

Alexandria, Va.—The two Alexandria transportation companies, after succeeding on May 13 in a plea for increased fares to become effective on June 10, withdrew their application for the increase before the State Corporation Commission on June 5. The fare was to have been 8 cents. The communication from the companies stated that a decision had been reached "to give the intrastate rates heretofore existing a further trial, hoping that the operation may be continued without the necessity for any increase."

More Convenient Service by Bus in Schenectady

The Public Service Commission has authorized the Schenectady Railway to operate buses in place of cars on the Rosa Road-Nott Street-Erie Boulevard line and the Crane Street line. The city authorities have consented.

Buses on the Crane Street line will be used on practically the same route over which cars now operate and they will also pass through certain streets not now served by the trolley line. The Rosa Road line will supplement existing trolley lines and serve a section of the city not now conveniently reached by the trolley cars. Transfers are to be exchanged between the trolley cars and the buses.

The bus service on the Crane Street line will provide through service from the Mount Pleasant section to the General Electric Works and an alternate route is provided over the Crane Street line so that special shop trips can be made over a more direct line, thereby saving about twelve minutes over present operation. There will be a ten-minute headway and four buses will be used.

The Rosa Road line will furnish service to residents of that section now required to travel at least two blocks to the Grand Boulevard line. This will afford a more direct and time saving trip between that section and the American Locomotive and the General Electric plants.

City and Railway Differ About Madison Fares

Officers of the Madison Railways and city officials have clashed over the proposal by the city that the company try a $1 weekly pass in the hope of increasing its revenue. The company wants a straight 10-cent cash fare and a fare of 5 cents for school children. The present schedule is 10 cents cash, 16 tokens for $1, three for 25 cents and a 5-cent fare for school children.

At the hearing before the Railroad Commission on June 9 Dudley Montgomery, vice-president and general manager of the company, declared that if a weekly pass were substituted for the sale of tokens the passenger revenues would still further decrease. City Attorney Lewis insisted that the company should at least try the pass. City officials contend that a further increase in fares will tend to drive patronage away. The hearing may not be resumed until July.

Separation of Suburban from Through Traffic

In its great Philadelphia station project, the Pennsylvania Railroad is planning to separate to a very large extent the suburban from the through traffic. The through traffic trains will all be handled at the main station, so constructed as to allow trains to go to or from the East, West, South or North, without reversing direction, as is now required. Suburban trains, serving territory within 30 miles of Philadelphia, west of the Delaware River, will all stop at the main station, but they will then continue on about a mile further to a new underground suburban station which is being specially constructed at Sixteenth Street and the Parkway, close to the long-established downtown business center. An overwhelming proportion of the commuters and frequent riders on these trains will use the underground station, while only a few will get on or off at the main station. Thus, the principle of separation or segregation, as between short distance and long distance travel, will be applied on a larger scale to a great railroad terminal project.

N.E.L.A. Delegates Leave New York

Headed by Matthew S. Sloan, president of the National Electric Light Association, who is also president of the New York Edison and affiliated electric companies, 210 members of the National Electric Light Association left the Pennsylvania station in New York on June 12 on a special train known as the "Blue Special" for the Pacific Coast, where they are scheduled to arrive June 15, the day before the 53rd annual convention of the association will begin.

Buses to Replace Rochester-Buffalo Railway Service

The Public Service Commission has granted the application of the Rochester, Niagara Falls & Buffalo Coach Lines, Inc., for certificates for operation of bus lines between Rochester and Buffalo and between Rochester and Niagara Falls.

The new company was organized in the interests of the Rochester, Lockport & Buffalo Railroad. The trolley operates 54 miles between Rochester and Lockport, running thence over the International tracks to Buffalo, carrying freight and passengers. The coach company is to be financed by the railroad and it will operate four buses at the outset, two between Rochester and Buffalo and two between Rochester and Niagara Falls. This number will be increased as service demands. It was stated at the hearing that due to competition with private automobiles, expense of grade crossing eliminations, signal installations, which it anticipates, together with possible paving costs in villages the railroad can not continue operation, and for that reason it organized the coach company. The company's petition amounts to a gradual substitution of bus service for trolley service between Rochester and Lockport and extension of the bus route from Lockport into Buffalo.

The company's petition to operate between Lockport and Buffalo was opposed by the Western New York Motor Lines, the Buffalo Transit Company and the International Railway. The Western New York line claimed the operation would be in direct competition with its buses between Rochester and Buffalo, but this contention, the commission holds, is not sustained by the facts. The Buffalo Transit Company claimed that there was adequate service between Lockport and Buffalo. The commission finds that the two lines would parallel for about 13 miles between Lockport and Sheridan Drive, but the new company is to be restricted and no passengers are to be carried boarding cars in either city for transportation to or from Lockport or Buffalo. The International Railway said that transportation facilities between Buffalo and Lockport are entirely adequate.

New Diesel Bus Tested

Some 40 bus operators and press representatives including one from ELECTRIC RAILWAY JOURNAL were guests of the Mercedes-Benz Company on June 11 at a demonstration and test of a Diesel-engine powered bus just received from the German factory of the company. The bus was operated on a run of about 30 miles at varying speeds in traffic. Its performance appears to be approximately equal to that of a gasoline bus of equal size and motor rating. Control of the vehicle is through a standard gear set and accelerator pedal. Low-grade fuel oil was used. The exhaust appeared practically clear and odorless.

The power plant consists of a six-cylinder Diesel engine with bore of $3\frac{1}{8}$ in. and stroke of $5\frac{23}{32}$ in. The weight is 1,400 lb. At the maximum speed of 1,650 engine r.p.m., the rating is 72 hp. The fuel is supplied to the cylinders by the usual fuel pump and through injection nozzles, and is fired by the heat generated during compression of the engine. To start, a storage battery operated starting motor of conventional type is used with an electric preheater warming "glow plugs" in the ignition chamber to create the necessary temperature for the initial explosions.

The engine has two blocks of three cylinders each, and the crankshaft is of the seven-bearing type and carries a vibration damper. The rods are of steel of double T section, while the pistons are of aluminum alloy. In the cylinder heads are an inlet and an exhaust valve of the overhead type for each cylinder, the fuel injector nozzle and the pre-combustion chamber. The valve mechanism is driven by push rods and rocker arms from the camshaft through helical gears. The water circulation system in similar to that in general use with gasoline engines for bus service.

It is stated that the engine and vehicle are now in production for sale in the American market. The National Railway Appliance Company of New York is the sales agent for the United States.

Detroit's Trackless Trolley To Be Fittingly Installed

Ceremonies befitting the occasion are planned for the opening by the Department of Street Railways, Detroit, Mich., on June 16 of service by trolley bus over a route of more than 5 miles on Plymouth Road between Grand River Avenue and the city limits. It is expected that Henry Ford will be among the prominent citizens who will attend. The city recently ordered six trackless trolleys from the Twin Coach Corporation.

H. L. Miller in New Post

H. L. Miller, has accepted a position with the Pettibone Mulliken Company as manager of electric railway division. Mr. Miller studied civil engineering at Bucknell University and joined the Engineering Corps of the Pennsylvania Steel Company, Steeton, Pa., on construction and plant maintenance in 1905, entering the frog and switch department of the company in 1907, resigning this latter position in 1910 to accept a position as draftsmen with The Buda Company at Harvey, Ill., with which he served continuously until March of this year. At the time of his resignation he held the position as chief engineer.

Trolley Buses for Queens

The Brooklyn & Queens Transit Corporation will ask the Board of Estimate for authority to replace some of its trolleys in the Borough of Queens with trolley buses. Officials of the company, promising closer co-operation with the Queens Highway Bureau, have agreed to aid in the shifting of the tracks on Corona and Way Avenues, Woodhull Street, Flushing Avenue and Metropolitan Avenue.

President Menden said he believed the most feasible plan is to substitute trolley buses for trolleys, so as to permit the removal of tracks from main thoroughfares. This would expedite traffic and would result in lower operating expenses for the company. The company plans to try out the trolley buses on the Junction Avenue route in Corona.

Accident Record Bettered in Kansas City

Four classes of accidents were reduced by the Kansas City Public Service Company, Kansas City, Mo., during 1929. Fell-in-car accidents were lower than they have been for four years. Collision-with-person accidents were reduced to the lowest point in seven years. Car collisions have been lowered more than 50 per cent in the last four years. The blind accident record showed an improvement. Vehicle collisions showed no improvement. Boarding and leaving accidents, and those involving injury by gates and doors, all increased. Two hundred and seventy-seven car and coach operators went through the entire year without an accident that was avoidable. Prizes given by the company are considered largely responsible for improvements in the accident record.

Yellow Coach Reports Best Month in History

General Motors Truck reports Yellow Coach deliveries for May as the largest in the history of the company, deliveries for the month amounting to more than $3,500,000. This sum represents sale of 403 buses, mostly of the large capacity type. The total compares with deliveries valued at $1,535,000 for the corresponding month of last year. Increased sales as reported are due to large orders recently secured from Public Service Co-ordinated Transport, the Greyhound System, Fifth Avenue Coach and other prominent motor coach operators. Coaches ordered and scheduled for delivery in June compare favorably with totals for May.

LATE NEWS

(*Continued from Page 424*)

Chicago, Ill. — The popularity of the service on Diversey Avenue has necessitated an increase in the number of buses originally planned by the Chicago Surface Lines on streets in the northwest section. More buses have been ordered and the installation of service on other streets covered by the order of the Commerce Commission will begin at once. Trolley bus service on Central Avenue, from Lexington Street to Milwaukee Avenue, was started on June 8. The streets, in addition to Diversey and Central Avenues, on which trolley bus service is to be installed are as follows: Narragansett Avenue, North Avenue, Elston Avenue. Belmont Avenue is being supplied with service by means of gasoline buses. Gasoline bus service also will be established on Irving Park Boulevard from Neenah to Harlem Avenue.

✦

New York, N. Y. — The *Financial World* for June 11 is the eighteenth annual public utility review. In addition to an analysis of more than 150 utilities, the issue contains articles entitled: "Forecasting Electrical Growth"; "The Growing Natural Gas Industry"; "Valuing Public Utility Securities"; "Ventures Into Foreign Fields"; "A Study of Utility Holding Companies," and "Analyses of More Than 150 Utilities."

✦

Detroit, Mich.—Recall petitions seeking to remove a mayor from office are being circulated for the first time in Detroit's history. Charles Bowles is the mayor. He was elected last fall to succeed Mayor Lodge on a platform calling for the quick and thorough cleaning up of the city. Now he faces removal on charges that he has permitted Detroit's underworld to ply its illicit trade openly. Another factor in the recall movement was Mayor Bowles' recent dismissal of Frank Couzens, son of Senator Couzens, from the street railway commission in charge of Detroit's municipal railway. The commission, composed of three men, recently voted to increase fares. Mr. Couzens protested vigorously.

✦

Portland, Ore.—Proposal of the Pacific Northwest Public Service Company to extend its 10-cent car zone to nearby points on its three main interurban electric lines and extend full transfer privileges has been discussed by company officials with members of the public service commission. Members of the commission pointed out that Milwaukie residents now riding on the fixed terminals plan will have to pay 10 cents from Milwaukie to First and Alder Streets instead of 7 cents as at present, but the company officials said that under the 10-cent zone plan a Milwaukie resident could ride to any point in Portland for the dime, whereas now, because of the fact that no transfers are granted at this fare, he would have to pay 17 cents.

✦

Greenville, S. C.—The Piedmont & Northern Railway has presented motions in Federal Court here asking that parts of the bill of complaint in the suit of the Interstate Commerce Commission and a group of steam railways against the electric line be stricken out. The commission and steam railways seek to secure an injunction against the $15,000,000 expansion program of the Piedmont & Northern. The case will be tried on its merits in Federal Court during the summer. The Piedmont & Northern is planning immediate resumption of work on the Spartanburg-Gastonia link.

Rockaway, N. Y. — Twenty-two municipally owned buses have been put in operation by the Department of Plant and Structures between Far Rockaway and Neponset, Queens. Soon after municipal operation started the police ordered off the streets all buses of eight non-licensed lines. The present arrangement will continue until satisfactory plans can be outlined for a permanent system. Mayor Walker has indicated that the general report on the bus situation soon to be submitted by the Board of Transportation would clarify the Rockaways problem.

✦

Boston, Mass.—The trustees of Eastern Massachusetts Street Railway took no action on June 10 on the quarterly dividend of $1.25 on adjustment stock due at this time.

✦

New York, N. Y.—The Transit Commission's suit to compel the Interborough Rapid Transit Company to live up to the 5-cent fare requirements of its contract with the city on subway and elevated lines and the company's litigation for a 10-cent fare on its elevated routes will make no further progress until fall. Both suits have yet to reach the Appellate Division calendar and that court is about to adjourn.

✦

Toronto, Ont.—Their names referred back twice without discussion and rejected entirely by the City Council at a special meeting, W. C. McBrien, former Comptroller Albert Hacker and S. J. McMaster, have been renominated by the Board of Control as Toronto Transportation Commissioners. The feeling prevails that some members of Council who voted against the recommended Commission will now change their votes. When the Board of Control met it decided not to name the commissioners, but later reconsidered its decision, and after several fruitless attempts to select other commissioners from names already suggested to it, renominated its rejected selections.

✦

Laconia, N. H. — The Laconia Car Company has voted to pay a liquidating dividend of $10 to preferred stockholders.

✦

Huntington, W. Va.—No further opposition by the city or business interests to rate increases sought by the Ohio Valley Electric Railway is planned upon the showing of the statistician's report civic and business leaders voted favorably on a resolution favoring relief for the railway and voiced their accord with any decision of the Public Service Commission.

✦

Winnipeg, Man.—An early decision regarding the application of the Winnipeg Electric Company for an increase in fares and relief from certain tax imposts, is indicated in the report of the auditors appointed by the City Council to examine the company's books. This report has been presented to the special committee of the City Council. Representatives of the company were present when the report was read to the committee, but a copy was not then available to the company. Despite this, company officials feel that the findings establish the fact that the company is entitled to relief much greater than it asked, and that the report confirms the facts set out in the company's application.

JOHN A. MILLER, JR., *Managing Editor*

Volume 74 | New York, July, 1930 | *Number* 8

The Industry Prepares to Carry Through

OUT of the 49th Annual Convention of the American Electric Railway Association recently held in San Francisco there emerged a very definite feeling that the path of progress for the local transportation industry lies in the direction of scientific study of its problems. At previous conventions there has been an enthusiastic acceptance of the idea of modernization. But progress has been comparatively slow in putting this idea into practice. Though the need for modernization was recognized, uncertainty existed concerning the best way to go about it. No quick and easy solution of the problem was evolved at this year's meeting. Indeed, it was generally recognized that there can be no quick and easy solution. Advances must be made step by step, and a quiet determination to knuckle down and study the situation until satisfactory solutions are found was evident on every hand.

Had the 49th Annual Convention accomplished nothing else than the crystallization of this sentiment, it would go down in history as having been a real success. But it did more. It brought together more closely than ever the electric railway men of the East and the West and the great central area of this country. Though the number of delegates attending the meeting at San Francisco was somewhat smaller than in other recent years, their geographical distribution was more even. A surprisingly large delgation was on hand from the East and also from the Central West. For many it required the expenditure of considerable time and effort to attend the San Francisco meeting, but all felt amply repaid. The attendance of Pacific Coast electric railway men was naturally much larger than when conventions have been held in the East. It is noteworthy, indeed that the total registration was substantially larger this year than at the last previous convention when there were no exhibits. That the 1930 convention should have been so well attended in a year of business uncertainty is an indication of the sincere appreciation which electric railway men have of the value of these annual gatherings.

Path of Progress Outlined by Executives

SELDOM has such a wealth of valuable material been assembled in a convention program as was presented before the American Association at San Francisco. The addresses were well delivered and gave evidence of careful preparation. Beginning with statements of the difficulties confronting the industry by President Shoup and Managing Director Gordon, the speakers discussed ably the various phases of the theme.

Of particular interest were those speakers who saw possibilities of immediate improvement in conditions without sitting idly by and waiting for someone to present a completed program. There is plenty that can be done at once, so that both public relations and physical plant can be improved without the expenditure of large sums of money. The remarks of J. E. Curtis, chairman of the Nebraska Railroad Commission, indicate that regulating bodies in general are willing to go more than half way in working out a program of cooperative effort involving the companies, their employees, and the communities they serve.

Naturally much interest centered in the plan proposed by the President's Conference Committee, which was explained in some detail by Dr. Conway. Undoubtedly this is one of the most important steps ever taken by the association, and its presentation was one of the high spots of the convention.

Good opportunity was afforded at the general luncheon conference held on Thursday, for a summation of the three sessions of the American association. Without a set program, it was possible to obtain a number of viewpoints on the effectiveness of the sessions. It was apparent that executives are prepared to carry through the program outlined by the association. Particularly significant were the confidence shown in the proposed car improvement plan and the general indorsement of it.

Optimism Is in Order

EACH year the electric railway industry is presented with records of accomplishments which challenge the most pronounced skeptics. These records are indicative of progress. Noteworthy improvements in operating conditions and better financial returns are being obtained on small as well as on large properties, and under conditions common to many sections of the country. An active incentive for the presentation of these accomplishments has been the Charles A. Coffin Foundation Award. For the past eight years this award has recognized and rewarded that electric railway which, in the eyes of the judges, has most definitely solved its own problems and contributed valuable guidance for other companies.

This year the award was made to the Youngstown Municipal Railway for its noteworthy achievement in modernizing its service, increasing its earnings and gaining the good will of the public. The record of this company is the more creditable in that it represents continued progress. Only four years ago the Coffin Award was won by the Pennsylvania-Ohio Electric Company, of which organization the Youngstown Municipal Railway is a part.

Among the outstanding accomplishments recorded in this year's presentations are the securing of new and satisfactory franchises which have relieved the companies of

Digitized by Google

many burdens and which will permit operation at a profit; modernization of equipment and plant; efficient co-ordination of street cars and buses; improving standards of construction, operation and maintenance; extension of chartered service and analytical accident prevention activity. These are not temporary measures applied to save or make money in an emergency. They are permanent and of such a nature as to assure further results.

To ignore the fact that the electric railways have traveled a hard and rough road during the past two decades would be futile. Cost of operation has increased materially while fares are practically the same. Many companies are burdened with obsolete franchises, with obligations never contemplated at the time of their making. New capital is hard to find because of an ignorance on the part of the public as to the efficiency and usefulness of the street car. But these obstacles are not insurmountable. Each year the Coffin Award contest shows conclusively that those companies which bend their efforts to the education of the public through careful merchandising and co-operation with local officials are solving these problems successfully.

Car Improvement Receives New Impetus

FOR several years past it has been realized that the key to the problem of the electric railways lies in the design of the car. While there has been general agreement concerning the need for rolling stock modernization, the progress actually made has been comparatively slow. Experiments with various innovations have been made by numerous companies but there has been little co-ordination of effort. Individual railways have insisted on the inclusion of special features in the design of their cars and have refused to incorporate ideas that have been developed on other properties. This insistence upon special design has resulted in keeping up the cost of rolling stock. Improvements in design have not been widely adopted. In fact, the electric car has practically stood still while its chief competitor, the automobile, has become better and cheaper.

To correct these conditions, a definite program has now been undertaken under the auspices of the Presidents' Conference Committee. Investigation convinced the members of this committee that sufficient authoritative information was not available as to the essential features which should be included in the design of the modern electric rail car. As the first step in its program, therefore, the committee has selected C. F. Hirshfeld, research engineer of the Detroit Edison Company, to make a thorough analysis of the needs of the situation and to develop plans for improving design.

It is not the intention of the committee to develop a standard car. Rather it is the intention to try out every worthy idea that is suggested in such a way that duplication of effort among the various electric railways will be minimized, impractical features of design will be eliminated and the best ideas will be promulgated for the benefit of the industry. In this work the committee will have the backing of railways representing more than 60 per cent of the potential car-buying power of the industry and will have also the co-operation of the car builders.

Undoubtedly this is one of the most promising proposals put forward in many years. As a result of this scientific research, it may confidently be expected that design of the electric rail car will be greatly improved. Such an undertaking, however, will require several years for its execution. Meanwhile the industry cannot afford to sit back and wait for the evolution of a perfect car. Already the railways have suffered heavily through the continued operation of obsolete rolling stock. Every effort must be made to replace this obsolete equipment as quickly as possible. Treatment of a critical ailment cannot be deferred in hopes of a more effective remedy being discovered at a future date. The fruits of research will be enjoyed in due time. For the present we must endeavor to take full advantage of the best designs now available.

The Engineer's Responsibility Is Paramount

ORGANIZED research along several lines, which is projected or already under way by the American Electric Railway Association and its affiliated bodies, has placed a large responsibility on the engineer in the transportation field. Plans for the improvement and standardization of cars, making market surveys in all branches of the industry and obtaining greater economy and efficiency of operation, all call for the highest skill the engineer can furnish.

As to the meetings of the Engineering Association, they showed a remarkable grasp of the problems that have attracted the attention of operating men for a number of years. The various committees made reports that showed a close attention to the subjects and skill in arriving at the proper solution. New equipment and new designs were studied. Latest developments in cars, buses and trolley buses were discussed and their particular advantages and disadvantages analyzed from the engineering viewpoint. Examination of the reports of the sessions and the papers which were presented discloses the breadth of scope coming within the purview of the engineer.

Looking ahead and planning the activities of the engineer for the immediate future, the general convention, as well as that of the Engineering Association, recognized the necessity for progress in five major directions. These were the absolute need for specialized merchandising of the service rendered, improved equipment and facilities, the continued development of design for greater comfort and convenience, the attainment of higher speeds and the acquisition of equitable franchises and rates of fare. The engineer must play his part in the working out of these problems. That is indisputable. The meeting in San Francisco emphasized this fact, and the engineers who were present could not but realize the responsibility which they must assume, not for their own property alone, but for the industry.

T. & T. Urges More Intensive Merchandising

PROGRESSIVE thinking on major topics of the day marked the work of the Transportation and Traffic Association during the past year. Reflected in the committee reports prepared and the discussion of them, at the San Francisco meetings, this thinking will be recorded as a definite contribution to the advancement of the industry. Since 1908, when the association was formed, it has contributed much through the work of its many committees. The 1929-1930 period brings to a head this previous study and advances many new ideas.

Handling one of the most important subjects, the

Digitized by Google

small-city committee continued its collection of data and information. Its report particularly emphasized the need for intensive merchandising. Better selling of the service is the first step the smaller railways should take, and it is encouraging that more attention is being paid to this fundamental requirement.

It is significant that another committee, that on the passenger, should strike down to the foundation of merchandising in its report. Feeling that a better knowledge of the desires of the public for transportation is essential, the committee selected a trained man to establish a scientific method of making market analyses. Intended to determine whether more rides may be sold to the present users and whether non-users can be induced to ride, these surveys will form a standard basis for adjusting service and building up revenue.

Although no direct reference was made to merchandising in the report of the committee on the transportation employee its suggestions for selecting and training men properly will assist in developing salesman. Analyzing the job of each employee is bound to show whether his relations with the public, his appearance and manner, and his ability to do his work will qualify him as a salesman.

Movement of the vehicle, operating economics and equipment were the other subject studies. An analysis of the effect of the automobile on riding is included in the report on the first-mentioned topic. It also gives valuable suggestions on making studies of parking and traffic control. The operating economics report lists many practices generally applicable which have increased revenues or decreased costs. Convincing figures on the beneficial effect of new or rehabilitated cars on revenue and expenses were presented by the equipment committee. Study of the statistics of 40 companies having new cars, and 41 companies operating old equipment, together with a detailed study of two selected cases, led to the one conclusion—that modern cars appreciably increase passenger revenue.

An Opportunity for Utilizing the Art of the Drama

KEEN interest is felt by all electric railway men in their industry and the discussion of its problems, but it is too much to expect that this interest should be so strong as to render them oblivious to the manner in which the subject under discussion is presented. A bright, lively presentation catches and holds their attention whereas a dull tedious presentation allows their interest to slip away. At electric railway conventions, too much reliance is sometimes placed on the importance of the subject as a means of holding the interest of the delegates, and not enough thought given to making the presentation effective. As a result, vital matters frequently do not receive the attention they deserve. It is a great pity that this condition should exist. The opportunity afforded by the annual A.E.R.A. convention for group consideration of transportation problems by executives from all over the country comes but once a year and it is extremely desirable that the fullest possible use be made of this opportunity.

To find a remedy for this situation is not easy. The busy railway executive has no time to study oratory before going to a convention to make an address. It would scarcely be diplomatic for the program committee to offer detailed suggestions in advance to the speaker. One possible solution of the problem might be for the committee to secure the advice of an expert on program arrangement. A man of this kind could render valuable service not only in suggesting how to treat individual subjects most effectively, but also in suggesting how best to arrange the various topics to be considered at each session and how much time should be allotted to each to avoid wearying the delegates. He might also be able to suggest a better balance between formal addresses, committee reports and informal discussion. In short, he would apply the art of the drama to making the program attractive.

It is no criticism of those responsible for the electric railway convention programs that something of this kind is needed. The members of the program committee are transportation men, not dramatists. But experts on the principles of program arrangement are available and could well be utilized. This would in no way detract from the impressiveness of the sessions. Even the most important subject gains emphasis from an interesting and effective presentation. A convention program should be more than a mere collection of topics which are believed to be timely and interesting. It should be put together with the same care that is exercised in the arrangement of a theatrical program in which each act is considered in its relation to the other acts.

Co-ordination Ahead for Chicago

VOTERS at Chicago on July 1, by an overwhelming vote approved the new franchise ordinance calling for co-ordination of all local transportation agencies. That augurs well for the future. Of course, the measure is not perfect. No human document ever is, but it is undoubtedly the best plan that has been proposed.

The old franchises were unsatisfactory in many ways. The idea behind them was to tie the companies up tight. And that they did. It is surprising that under them the companies did as well by the people of Chicago as they did. So far as it was possible to do so under the restrictive grants in force progressive managements of both the surface lines and the elevated have given the public a taste of what could be expected under a grant fair alike to the companies and the city. They kept faith in the larger sense of their civic responsibility. And they have been rewarded and the city has been rewarded by acceptance of an ordinance probably without parallel in the annals of franchise grants of the kind.

It will take some time to work out the financial details, but the stage is all set. Financing is a matter of technique. While this is also true with respect to the plan for the expenditure of $60,000,000 within the next three years and $200,000,000 within ten years, the work of aligning the properties physically can be begun at once and may be expected to proceed promptly.

In the form in which the grant was finally adopted and now passed the ordinance represents many years of effort to find a solution to the question and many months of intensive work by various officials and civic groups. Under it the new co-ordinated company, the Chicago Local Transportation Company, will be enabled to give the millions of people patronizing its lines efficient and satisfactory service. Transportation in Chicago may now be expected promptly to get into step with the march of progress of the city's other utilities. That has been a hope long deferred. Now it should soon be realized. Both the companies and the city are to be congratulated on the outcome.

Newly-Elected Presidents

of the AMERICAN and AFFILIATED ASSOCIATIONS

1. **J. H. HANNA,** elected president of the American Electric Railway Association, is president of the Capital Traction Company, Washington, D. C., with which and its predecessors he has been connected since 1894. He knows that property and the personnel intimately, and he knows the transportation industry. He is the first man ever to have been president of both the association and its affiliated body of engineers. Long has he been active and prominent in association work. He is well known and well liked, locally and nationally. He is an engineer with vision, as his administration of the Washington property testifies. Mr. Hanna was graduated from Princeton in 1892 as a civil engineer.

2. **L. D. BALE,** elected president of the American Electric Railway Engineering Association, is superintendent of the power department of the Cleveland Railway. His greatest contribution to the industry is the work that he has done in developing the automatic substation. He has seen service with the Louisville Railway, the St. Louis Transit Company and its successor, the United Railway, and with the Cleveland Railway, with which he became associated in 1908 and for which, starting in 1911, he revamped the entire power supply system. He has been unusually active in association affairs. He studied at Rose Polytechnic Institute, but not until after he had served as an apprentice with the Louisville Railway.

3. **PAUL E. WILSON,** elected president of the American Electric Railway Transportation and Traffic Association, has been connected with the Cleveland Railway since 1902, but not continuously. His first work was as office boy. Again he was with the company from 1905 to 1908, in the operating department. Then he served the Cleveland *Leader* and the Cleveland *Press* as reporter, studying law meanwhile at Western Reserve University. His return to the railway dates from 1910. His advance to the post of vice-president and secretary was rapid.

4. **C. E. REDFERN,** elected president of the American Electric Railway Claims Association, is claim agent of the United Electric Railways, Providence, R. I. He entered the service of the predecessor of that company in 1900 direct from business school, transferred to the claims department in 1902, and was made claim agent in 1907. His chief interest is in safety work because of its direct bearing on the affairs of his company and its humanitarian aspects. He is on the executive committee of the National Safety Council and is a member of the Governor's committee in Rhode Island on street and highway safety. Mr. Redfern was admitted to the bar in 1921.

5. **C. E. YOST,** elected president of the American Electric Railway Accountants' Association, is treasurer of the Delaware Electric Power Company, Wilmington, Del. This company is the successor to the Wilmington & Philadelphia Traction Company with ramifications more extensive than the company's title would appear to imply. In the work of the company, Mr. Yost has played a very important part.

Co-operation Is Essential To Meet *1930's Challenge to Transportation*

In his presidential address before the American Electric Railway Association Mr. Shoup points out the problems that confront the industry and outlines a means of solution

By PAUL SHOUP

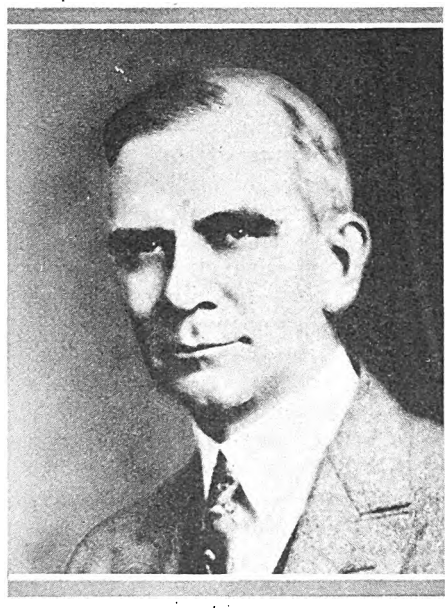
President American Electric Railway Association,
Chairman of the Board Pacific Electric Railway

DURING the fifteen years since the American Electric Railway Association held its annual convention west of the Rockies, many changes have occurred in the whole transportation structure of the nation, the local transportation industry in particular. It has been forced to contend with shifting economic, political and social forces that have put to a most severe test the industry which you represent, and in which there is invested some five and one-half billions of dollars; almost a fifth of that invested in steam railroads.

Out of this battle for existence there is coming a more virile industry. Useless branches of the transportation tree have been swept away by the storm of conflict or removed in the interest of more efficient service. The trunk remains permanently rooted in community soil.

You may well take pride in the recent record of the industry. We are passing through a general severe industrial depression. The output of some of our major industries has been temporarily greatly curtailed. Our local transportation industry has shown only moderate effects from these depressing causes. A non-essential or fading industry does not establish a record like that in times of depression.

It has been increasingly apparent for twenty years that transit and traffic conditions in American cities should receive attention. Transportation facilities in the majority of the larger cities of the country have been permitted to fall far behind the standards for other elements in modern urban life. Measured in terms of convenience, comfort and safety, the conditions to which people in most cities are subjected when they attempt to move about, reflect little credit upon American progress. Inconvenience, crowding and dangers encountered in riding, driving or walking in congested traffic areas have come to be accepted as almost inevitable. That should not be so.



Paul Shoup

The remedy for these conditions lies in the hands of transportation men and the public working co-operatively. It is part of our job to show the public what the remedy is, and how we can join hands and apply it. The job is worth doing, and worth doing well. Unless I am greatly mistaken, eventually it will fully reward the men who do it.

Companies providing public transportation service in cities are seriously handicapped by the lack of public understanding of the problems involved and consequent lack of public co-operation. Measures for the improvement of the service naturally raise many public issues that are complicated, and to some extent of a technical nature. Any sound program of improvement must put the needs of the community as a whole above the interests of a particular section or group, but partisan politics, prejudice, and, finally, selfish interests of individuals or groups, tend to obstruct progress. There is need, therefore, for a better understanding by each community as to transportation policy that will be most beneficial to it as a whole.

Back of our so-called street traffic problems lies the major problem of transportation. Traffic and transportation are closely related in their activities. It is not my part to discuss a solution; I will mention but a few of the problems that are up for solution. These concern not only our companies engaged in this public service, but the cities and communities thus served.

Digitized by Google

Here is a vital and necessary utility service which carries seventy-five per cent of all the people who move daily in and out of the central areas of large cities. The industry ranks about eighth in the amount of invested capital in the United States. But while the difficulties of other industries attract attention as national business problems, the long protracted struggle of the local transportation industry to maintain a vital public service while handicapped by serious economic and political obstacles attracts far less public attention than is warranted by its importance.

This situation is the more to be lamented because of the fact that relief can be given at no expense at all to the public. With such relief will come a vast improvement in personal comfort, in convenience, in maintenance of home and business values, and creation of new values for all the people of the communities served.

It is absurd, as was shown by the recent report of a State Taxation Committee of the State of California, that the electric railway industry—the least remunerative of industries in this state—should be bearing the highest tax relatively compared with all other public service corporations. It is absurd that these companies should be compelled to continue the paving and maintenance of sections of streets and highways—in many instances the major part—when it is the tremendous traffic of the last few years of motor vehicles used in private service that is wearing them out.

The uncertain policies of the cities with respect to franchises, whereby the owners of invested capital do not know when it will disappear absolutely, and the thoughtless use of police power that puts added operating burdens upon the companies in so many localities, can be so easily and simply removed, in so far as the mechanics of the problem are concerned, that it seems almost unthinkable that enlightened policies have not been established, since they are so essential to the life and growth of the cities.

Experience has indicated that the construction of rapid transit structures, either subway or elevated, is not a suitable field for the investment of private capital. Due to high fixed charges, the riders cannot furnish revenues sufficient to carry the fixed charges, and maintain these structures. The question then arises, if the necessity takes on a conclusive aspect, as to who is benefited, and who should help carry the charges that are not properly allocable to the riders, because of the greater convenience and more rapid transit given them in their transportation.

It is believed by some students of this question that a clearer understanding is needed of the distribution of benefits from transit improvements among the several groups in a city which are affected thereby; namely, the community as a whole, property directly enhanced by the location of transit lines, and the riders who use the service. Though the property which receives direct benefits from the location of transit routes plays a very active part in dictating the location of lines and even of stations, it has so far failed to carry its proper share of the construction cost burden. In this fact seems to lie the difficulty both financial and political of providing adequate rapid transit.

Few companies in the United States are able to pay a satisfactory return to their investors, even though the average rate of fare has steadily risen during the past decade. In consequence, the financial and physical status of electric railways in many cities is in serious jeopardy. As a result, the communities are faced with large expenditures for increased street capacity, because the public very naturally prefers to use its automobiles as a substitute for public transportation when the latter is not permitted, through either political, physical or economic handicaps, to develop the class of service to which the public feels itself entitled.

Nor is the outlook for other public agencies of urban transportation much better without adequate public co-operation than is that for street cars. The bus, though rapidly finding its level as an adjunct to other transportation agencies, offers no permanent solution of present difficulties. It merely furnishes another tool of transportation that fits in between the individual automobile and the street car, and is particularly adapted for furnishing certain forms of service. In general, it has been clearly established that the wholesale replacement of street cars with buses, though it would involve the wiping out of an investment amounting to several billions of dollars in present street railway plant and roadbed, would complicate rather than simplify the urban transportation and traffic problem. One fact is definitely established: in any city, buses and street cars need to be operated in harmony and under one management.

Next, we come to the individual public vehicle—the taxicab. Here again we find an unsettled and unsound financial condition. As a matter of fact, the situation is such that it is unattractive to responsible capital and the growth of unregulated and destructive competition has resulted in widespread evils, and in some large cities is a major factor contributing to the traffic congestion problem.

Thus we have in every form of public transportation service in cities, in rapid transit, street railways, buses and taxicabs, the same general situation—unstable and unsatisfactory present conditions which threaten to become worse. At the same time there is no generally accepted policy under which these facilities may be expected to grow and develop.

The conditions to which pedestrians are subjected in present day traffic are a serious reflection upon our ability to provide for the intelligent and safe use of the machines which we ourselves have created. All of this is attributable to destructive policies, inadequate planning, and improper regulation to meet changing conditions. There seems to be great need for more general recognition of the relation between transportation and traffic in order that improvement programs may be developed on a basis broad enough to insure substantial relief and to provide for future requirements.

The situation has been summarized for me in this sentence: Cities cannot get along without local public transportation, and local public transportation cannot get along without the cities. But the cities and communities need to realize their obligations in this connection, because of their own interest, irrespective of the contractual relations that were entered into under different conditions when those companies first took on the obligation of carrying the public locally. The congestion in the business areas reaching points of stagnation, as I have said, makes more essential than ever before a complete co-operation involving the city governments, the public organizations seeking to solve the problems, the automobile associations, the transportation companies, and the individuals. These last named are very changeable, having, as each one of us knows, varying viewpoints according to whether they are on foot, riding in street cars, taxicabs, or in automobiles, or merely the immobile statues of patience waiting for these moving activities to get out of the way.

Meeting the Problems of Today in the Transportation Field

American Association sessions discuss vital subjects affecting the industry from many angles

THIS year three sessions of the American Electric Railway Association were held at San Francisco, on June 23, 24 and 25. The general theme of the convention was "1930's Challenge to Transportation Men." Each day the subject was treated from a different angle. On Thursday there was no formal meeting, but a general luncheon conference was held at the Fairmont Hotel, at which those present informally summed up the convention.

Monday's session, which marked the opening of the convention, began with the presentation by the chairman, President Paul Shoup, of Hon. A. J. Rossi, acting Mayor of San Francisco, who welcomed the delegates in most cordial fashion.

In his presidential address, Mr. Shoup sketched the development of the local transportation industry, pointing out the essentiality of the service rendered and the impossibility of building up great cities without adequate transportation.

Following Mr. Shoup's address, D. W. Pontius, president of the Pacific Electric Railway, Los Angeles, delivered an address giving in some detail the things that can be done to improve interurban operation and revenues.

"Making the Most of Existing Street Railway Properties" was the subject of an address by Samuel Kahn, president Market Street Railway, San Francisco. The problem, he said, is the same as it was in the horse car days. The desirable features of service include speed, frequency and comfort. The standards by which the public measures the service, however, have changed and it has been necessary to revamp the traction systems time after time. He believes it is necessary to cater to the needs of the patrons and to their whims as well. Fast schedules without layover, he thinks, are essential if a company would succeed.

Abstracts of the addresses appear elsewhere in this issue.

The Industry's Plans to Help

TUESDAY morning's session of the American Association opened with the report of Managing Director Charles Gordon. He emphasized that in order to provide a satisfactory solution of the street railway problem public understanding is necessary. In order to obtain results it is essential that greater interest be taken in the work of the association and that co-operation be obtained from representative business men in the various cities of the country.

Announcement of the Anthony N. Brady Memorial Safety Awards was made by Mr. Gordon. In his remarks he stated that the record made by electric railways is a bright spot in a generally depressing traffic situation. The electric railways have had a comparatively small number of accidents in comparison with other vehicles operating on the highways; in particular, fatalities are exceedingly low.

The award of the gold medal for Class A roads, those operating more than 5,000,000 car-miles per year, was made to the Duluth Street Railway, with honorable mention to the Ottawa Electric Railway.

The silver medal for those roads operating between 1,000,000 and 5,000,000 car-miles annually was awarded to the Colorado Springs & Interurban Railway, with honorable mention to the Calgary Municipal Railway, Calgary, Alberta.

The bronze medal for those roads operating less than 1,000,000 car-miles per year was awarded to the Lethbridge Municipal Railway, with honorable mention to Montana Power Company, Missoula division.

Nominations were announced by Frank R. Coates in the absence of James P. Barnes, chairman of the committee on nominations. The nominees were elected unanimously as follows:

President—J. H. Hanna, president Capital Traction Company, Washington, D. C.

First Vice-President—G. A. Richardson, vice-president and general maanger Chicago Surface Lines, Chicago, Ill.

Second Vice-President—J. H. Alexander, president Cleveland Railway, Cleveland, Ohio.

Third Vice-President—W. A. Draper, president Cincinnati Street Railway, Cincinnati, Ohio.

Fourth Vice-President—W. E. Wood, vice-president Engineers Public Service Company, New York, N. Y.

Treasurer—Barron Collier, president Barron G. Collier, Inc., New York, N. Y.

Members-at-Large of Executive Committee:

Operating Members (Three-year term)—Dr. Thomas Conway, Jr., president Cincinnati & Lake Erie Railroad, Philadelphia, Pa.; G. J. Kuhrts, president Los Angeles Railway, Los Angeles, Cal.

Manufacturer Members (Three-year term)—E. P. Waller, manager transportation department General Electric Company, Schenectady, N. Y.; C. R. Ellicott, vice-president Westinghouse Traction Brake Company, New York, N. Y.; A. A. Hale, vice-president Griffin Wheel Company, Chicago, Ill.

Myles B. Lambert was elected to fill the unexpired term of E. D. Kilburn, resigned.

E. J. McIlraith, Chicago Surface Lines, addressed the meeting in the absence of G. A. Richardson, vice-president and general manager of the same company. He outlined briefly the work done by the committee on street traffic economics. Mr. McIlraith believes that use of the streets must be regulated in order to help a city grow in a logical manner.

Decentralization of some businesses, such as grocery stores and drug stores, is desirable, according to Mr. McIlraith. These businesses are more or less local in character and there is no advantage in concentrating them at a few points. Other businesses should be grouped together in order to get the best economy of time of those working in them. He believes that centralizing of many lines of business is increasing and

Digitized by Google

cited New York, Chicago and other cities as proof of this. With this development under way the street railway is not on the way out but is going ahead along with this tendency. In Chicago ten years ago there was a question of whether the streets would be adequate to handle the traffic that was being offered and whether it would not be necessary to distribute business over a much wider area on that account. Today, he said, there is no doubt about it. Changes in traffic regulations and elimination of parking have made it possible to move such an enormously increased number of people in and out of the central district that there is plenty of space for growth in business interests for years to come.

Street railway men must take the leadership in traffic regulation and control in order that it will serve the whole public. Signals of archaic type have been developed and introduced in cities to their great detriment. Mr. McIlraith gave several instances of this, indicating that advanced forms of traffic control are absolutely essential.

Progress in meeting the industry's equipment problem was the topic of an address by Dr. Thomas Conway, Jr. Dr. Conway outlined the work that has been done by the present committee which has been formed to investigate the problem of better design of street cars. He indicated that a new method of approach must be adopted in order that cars may be designed which will better meet the needs of today and can be sold at reasonable cost.

Edward Dana, general manager Boston Elevated Railway, addressed the meeting on the technique and possibilities of conference training for employees, summarizing the work done by the committee on employee training. This committee, he said, believes that the conference method of training is the most important that can be adopted in instructing employees in the technique of their positions. Methods already in use to train men to do their work on the cars efficiently is entirely satisfactory. What is needed is training for salesmanship—selling rides to customers. The most striking feature in the conference method is that it interests the individual worker. Considerable work has been done in the past few years in training foremen through conferences. The experience gained in this is most valuable in formulating plans for a broader type of training that can be adapted to all employees. Experience indicates that what should be taught is customer contact. The first thing necessary in selling car rides is to determine what is a satisfactory ride, and the next necessary thing is to determine what is satisfactory service.

Edward Dana

H. G. Taylor

Who presented addresses before the American Association

The conferences that have been successful in Boston in carrying out this plan have been quite short, lasting one to 1¼ hours. It has been possible to interest all of the men and to have each one take a part. Mr. Dana outlined in some detail the courses offered to foremen and supervisory officials in Boston. He stated that it is necessary to emphasize the relationship of the employee toward his job and toward the public. It also is necessary to develop in him a feeling of loyalty and desire to give the best service possible. Another need in the training is to develop a technique of customer contact. In this particular the conference method is the only approach that is of value in instructing adults.

Future of Public Control

AT THE Wednesday session of the American Association the *Electric Traction* Speed Trophy was awarded for the year to the Chicago, South Shore & South Bend Railroad. The presentation was made by J. M. Bamberger and the cup was accepted by W. A. Sauer, vice-president of the railway.

Mr. Shannahan reported on the relations of the association with the United States Chamber of Commerce. This, he said, is the only way the American business man has of making his needs known and it is essential that the electric railways be recognized as a vital element in American industry.

Mr. Shannahan then discussed briefly the relationship companies should have with their employees. The man on the platform of the car is our greatest potential asset, he said. Every operator should take advantage of the plans that have been developed by Mr. Dana's committee on employee relations and adapt them to its individual needs. He told in some detail of the change in sentiment of the public in Omaha since he has been associated with the company and where the public relations were previously very unfavorable. The improvement he credited to the work of the trainmen in engaging the support of the riders and the voters in general. This support made it possible to have a new franchise presented and adopted. Later on the same men made it possible to obtain a much-needed increase in fares.

H. G. Taylor, manager public relations, car service division, American Railway Association, addressed the meeting on the advances in transportation and the problems that have been brought with them. He mentioned briefly the great development in air transport during the past five years, and also the development of the motor bus. The bus, he said, has now taken its place alongside the street car, not to replace it nor to compete with it, but as an ally. Economic conditions must be recognized in the determination of rates of fare, according to Mr. Taylor. This contemplates regulating traffic conditions, which are chaotic all over the United States. The sentiment in favor of automobiles as against everything else, he believes, is waning and the street car is coming back into its proper field.

Digitized by Google

Need of better street cars was emphasized by the speaker. As illustrating his point, he told of the progress made by the steam railroads, which since 1920 have put a large amount of capital into the business and as a result have been able to obtain economies resulting in a great increase in net revenue. The program for improvement of car design which was adopted at this convention he believes is excellent and that it should lead to good results. Old cars, he holds, advertise the business as decadent and should be retired as soon as practical.

Mr. Taylor believes that there should be close co-operation between street railways and public utility commissions. There should be an interchange of information and better understanding of the problems involved. As to the future of the street railway, he is optimistic. He believes that it is an essential industry. However, the idea must be sold to the public that it is superior to any other form of transportation in its field and he believes that this has not yet been done.

An outstanding address was delivered by John E. Curtiss, chairman Nebraska State Railroad Commission, on the subject "Public Responsibility in Regulating a Competitive Industry." Illustrating his remarks with pointed anecdotes, Mr. Curtiss said that competition itself makes a very effective regulation which determines the maximum rates that can be charged and dictates to the managements the need for efficiency and economy.

An address on the subject of taxation was read by M. D. Lack, tax counselor California Taxpayers' Association, Los Angeles.

An address on the subject of "National Relations," giving the results of the work accomplished during the year by the American Association committee on that subject, was read by Ralph Bradley in the absence of C. D. Cass, general counsel American Electric Railway Association.

Following the adoption of report of the committee on resolutions the new officers present were installed. The meeting closed with an ovation to the retiring president, Paul Shoup.

Luncheon Conference Summarizes Situation

AS A FITTING climax to the convention, a general luncheon conference was held Thursday noon, after the official closing of all other meetings, for the purpose of summarizing the high spots of the convention and analyzing the future prospects of the industry. The chairman was D. W. Pontius, president Pacific Electric Railway.

In opening the comments on the convention, Dr. Thomas Conway, Jr., Cincinnati & Lake Erie Railroad, spoke of the President's Conference plan and its purpose of co-ordinating all developments of the past and future in the perfection of the street car. He cautioned against the expectation of startling results immediately and stated that only through a slow, orderly advance could progress be made. "The success of the efforts," he said, "depends on the co-operation of all electric railways and manufacturers."

Frank Karr, Pacific Electric Railway, gave his impressions of the convention and the principal things derived from the meetings.

Striking the keynote of the convention activities, W. B. Brady, Central Public Service Corporation, voiced optimism in the future of the industry because the problems are being attacked scientifically. He pointed to the new car plan, the recognition of the need for merchandising, the specific efforts in this respect through the introduction of market surveys, and the further studying of what properly may be termed a scientific fare structure.

Samuel Kahn, Market Street Railway, lauded the seriousness with which the problems of transportation were attacked, and cited the convention as the beginning of a new era.

That the association must broaden its scope of activities and include every form of public transportation was the view expressed by Julian M. Bamberger, Bamberger Electric Railroad. "We cannot be satisfied," he said, "with being street railway men. We must become public transportation men." Mr. Bamberger also commented on the lack of symposiums, discussion and attention to the problems of the interurban, and voiced the opinion that some means must be obtained of securing more collective data on specific problems.

Acquainting the public with the industry's problems and burdens is one of the vital needs, according to A. J. Lundberg, Key System Transit Company. Before giving them the facts, however, the railways must put their house in order, he added.

In the opinion of R. O. Crowe, Los Angeles Railway, the biggest thing which the delegates will carry from the convention is a renewed enthusiasm and faith in the industry.

"Find out how to sell your product," was the advice given by O. A. Smith, Pacific Electric Railway. Mr. Smith commended the merchandising activities started during the past year and added that all of the fundamental problems of the industry must be attacked from a merchandising angle.

Attractive service and well trained salesmen are the two biggest needs at the present time, according to A. T. Mercier, Pacific Electric Railway.

"The President's Conference plan and the making of surveys to determine what the public desires," stated Edward Dana, Boston Elevated Railway, "will open up a new effort in accomplishing the plans for modernization which have been under way for some time and which all railways have considered necessary."

J. M. Shannahan, Omaha & Council Bluffs Street Railway, commented on the seriousness with which the delegates engaged in the meetings and praised those responsible for the perfect convention arrangements and the splendid entertainment provided.

Three subjects, all of vital importance, were covered very thoroughly at the meetings, the comfort and convenience of passengers, fares, and speed. "The full discussion of these," stated J. H. Hanna, president of the Capital Traction Company and new president of the association, "will go a long way in attracting riders and making the public desire to use the service."

S. B. Way, Milwaukee Electric Railway & Light Company, commented on the service rendered by the San Francisco systems, and praised the work of the committees in charge of this year's program.

Charles Gordon, managing director of the association, summed up the high points of the convention and added an optimistic note to the closing. The obtaining of the other man's view at a convention of this kind, he pointed out, enables the interpretation of his ideas and the use of these throughout the entire year. Mr. Gordon spoke of the great responsibility, other than that of moving people, of acquainting the public with the problems and learning more about how the people wish to travel.

CO-OPERATIVE EFFORT

Is Essential

By CHARLES GORDON
Managing Director
American Electric Railway Association

Charles Gordon

COMPARED with other classes of utility services, local transportation companies are seriously burdened by limited man power and small staffs—particularly at the top. The long period of inadequate earning and unsettled future which we have experienced, has forced the most rigid economy in every department. Consequently, the chief executive of the average company is burdened with a heavy personal load.

There is still another situation which is above all the most discouraging with which the executive of a local transportation company has to deal. This is brought about by destructive tactics of the self-seeking politician who has little sincere interest in the transportation problem beyond the opportunity which it offers to get himself favorable notice in the press as a champion of the people at the expense of a corporation. The railway executive seeking intelligent public consideration of the many problems which he faces in his effort to preserve and rehabilitate a vital service to the public, is still frequently hamstrung and kept on the defensive by this type of political buffoonery.

Nevertheless, the situation with which an individual company contends is in a large measure circumscribed and materially influenced by developments in many other communities. Consequently, the action of each management and each community influences the situation of every other property in the country. Collective study of common problems and the very closest possible co-operation between companies is therefore of paramount importance.

Those of our current problems which lend themselves best to collective action, divide logically into six principal elements. Three of these have to do with the technique and methods within our industry; the other three involve questions of public policy which we can influence only indirectly, and then only in the development of policies and the application of measures intended to serve the best interests of the community as a whole.

Within the first group I place the equipment with which we render service—the general character and performance of the cars which we operate. The importance of this question has been recognized for several years and it has a prominent place on the program of this convention.

Second is the human factor in our business; that is, the attitude and the skill displayed by our employees in direct contact with the public.

It is absolutely essential that we have their full co-operation. But loyalty and the desire to co-operate are not alone sufficient. In addition, modern transportation conditions require a high degree of skill both in the operation of equipment through congested streets and in dealing with the public that boards our cars.

The third factor is the method of charging for our service. First of all, the product itself must be saleable. Next it must be sold by the people with whom the public is willing to do business. Finally, the price must be right. Other factors have an important bearing. Not the least of these is the presence of competition. Where it exists it exerts a strong influence on the making of rates or prices.

Turning now to questions of public policy upon which we can do little more than seek intelligent co-operation, there are again three principal problems which lend themselves to co-operative effort by the industry. There are three outstanding questions —taxation, franchise terms and regulatory policy, and the extent to which the efficiency of public transportation is recognized in seeking relief from street congestion.

All three of these topics—taxation, regulation and the economics of street use—have an important place and I shall do little more than merely mention them.

As I have already indicated, the development of local transportation is so interwoven with that of the community itself, that many of our problems are likewise public problems. If we are to unite upon the advocacy of measures based on certain general principles, these principles must be sound from the standpoint of the public interest, not in one community alone, but in cities of various sizes and varying characteristics throughout the nation. We know that the action of one community frequently affects many others. We have had ample evidence of this in matters of franchises, fares and taxation. We also know that each operating property is dependent for its development upon the state of the technical art in the industry as a whole. This is illustrated by our present efforts to develop more satisfactory types of car and bus equipment. With all this in mind, therefore, the importance of co-operative planning and co-operative action cannot be over-emphasized.

I am convinced that the business in which we are engaged renders a vital and necessary service which the 16,000,000,000 passengers who use it each year could not get along without.

There is every reason to believe that the business of providing public transportation service can be put on an economically sound and stable basis. I am fully aware of the difficulty and complexity of the problems involved. But I am hopeful that with your continual confidence and co-operation we may make steady progress and that my reports in the future may be expressed not in words but in results.

Meeting the Industry's *Equipment Problem*

Progress of the work of the Presidents' Conference Committee summarized in a significant address before the American Association

By THOMAS CONWAY, *Jr.*
President Cincinnati & Lake Erie Railroad
Chairman Philadelphia & Western Railway

IT HAS been generally recognized by the industry that progress is required in two directions: (1) improvement in the character of service rendered so as to make it more attractive to present and prospective patrons; (2) a substantial reduction in costs. Both factors are controlled largely by the design, age, condition, performance, weight and cost of the equipment operated.

Thus we are brought to the inevitable conclusion that the cars which we operate represent in large measure the key to our problem. For several years the industry has been aware of the evils attendant on the operation of the large number of obsolete and heavy cars that are in service, and it is gratifying to note that in the year 1929 a total of 1,496 new cars and locomotives were purchased by electric railways as compared with 897 in the year before.

In spite of the fact that the total number of cars purchased by electric railways in 1929 was 68 per cent in excess of the 1928 purchases and that a substantial number of cars were purchased during the first part of the current year, the progress of the industry in modernizing its equipment continues to be discouraging. There are approximately 74,000 electric railway passenger cars in the United States, most of which are in regular use. Half of these, or almost 40,000 cars, are over twenty years old. These old cars are excessively costly to operate, noisy, obsolete in appearance, and not calculated to stimulate riding or to earn a profit.

What is the reason for this anomalous situation? Why is it that an industry with over $5,000,000,000 of invested capital should cling to antiquated equipment instead of ruthlessly scrapping obsolete facilities as a means of promoting progress and increasing its earning power? The most important reason is that, while substantial progress has been made in the evolution of the railway car, it has not entirely measured up to the expectations or requirements of the shrewd railway executive. The competitor of the railway car is the private automobile and by the standards of the automotive industry the comparative progress of our industry in large part must be measured. Judged by that standard, the evolution of the urban railway car has failed to keep pace with its rival. The 1930 model automobile is infinitely superior to the product of five years ago.

Thomas Conway, Jr.

While the private automobile and motorbus are decreasing in cost, the electric railway car is constantly becoming more costly. Many operators refuse to buy cars to replace old equipment now in service because of what they regard as the prohibitive cost of the type of equipment which they would consider purchasing.

About a year ago a comparison of views and an exchange of ideas began between a number of the senior executive officers of large electric railway properties concerning the problem of car improvement. The upshot of the matter was that at the October, 1929, meeting of the Advisory Council, this question was brought up and thoroughly discussed, and it was informally agreed that steps should be taken by the railway operators to expedite the development of the urban railway car. To that end, I was requested to make a study of the problem and to prepare for submission to a group of the senior executives of our large city properties a memorandum outlining a plan of procedure to achieve the desired end. A notable meeting of the executives of such properties was held in Chicago in December last at which the so-called Presidents' Conference Committee (of which I have the honor to be chairman) was organized. Steps were taken to secure subscriptions aggregating at least $500,000, in roughly equal proportions, from the interested railway companies and from the manufacturers.

At the last meeting of the Presidents' Conference Committee held in Chicago on May 22, a subcommittee was elected to select a chief engineer and to make arrangements therewith. After a most thorough canvass of the problem, the committee unanimously decided that a knowledge of car building or of the operation of railway properties was not a prerequisite to the position and in many ways might constitute a handicap, particularly in the highly competitive situation which exists in the car building industry. We were advised by some of the foremost engineers and business executives of the country, who have had wide experience in handling research projects, that what was needed was an engineering executive—a man who has demonstrated his ability to conduct large research projects and bring them to a successful conclusion; who has shown his acumen in the selection of technicians, each capable of handling a particular part of the work, and who possesses the personal qualifications of winning co-operation and begetting confidence from the engineers and executives of the various manufacturing interests involved.

After a most careful study of the men suggested, the nominating committee, elected by the Presidents' Conference Committee, has unanimously selected C. F. Hirshfeld of Detroit, Mich., who for many years has been head of the research department of the Detroit Edison Company, as the chief engineer of the committee. Mr. Hirshfeld has had a wealth of experience in conducting research projects for his company, for the National Electric

Digitized by Google

Light Association, and for other interests. He is not a railway car specialist; he is relying upon the active co-operation of our master mechanics, of the engineers and technicians of the car builders, the manufacturers of electric equipment and of braking apparatus, and of other groups whose products enter into the railway cars.

In considering how a group of associated operating companies may bring about a radical improvement in the present car situation, which is so important to the industry, two broad courses of procedure are open. The first is for these properties to appropriate a substantial sum of money, hire engineers and proceed to take the initiative in designing, building, and testing one or more cars to meet their requirements. Although this procedure might seem to offer the most direct method of attacking the whole problem and of bringing about immediate results, it contains a number of serious objections, one of which is the problem of finding engineering talent which may be expected to be more successful in producing results under operator sponsorship than could be achieved by keeping the initiative entirely or in large part in the hands of the manufacturers who have had very wide experience in design and in the details of construction.

It seems wise and most important that the whole future of car development should not be contingent upon the success of any one or even several designs. The best results can be expected through the simultaneous effort on the part of as many individuals and groups as can be interested in the problem. By working through and with the present manufacturers, the committee may expect to stimulate the maximum number of simultaneous development projects, which in turn is the method which seems to offer the greatest assurance of ultimate success. By pooling the influence of a representative group of important properties, it can coordinate the efforts of the manufacturers and eliminate confusion.

The committee plans to take advantage of the natural stimulation of competition in attempting to achieve its objectives. Competition between manufacturers in the effort to excel is potentially a strong force, which, if properly stimulated and directed, will tend to accelerate development. It would be unwise, therefore, to stifle this competition by taking development initiative out of the hands of existing manufacturers.

The purpose will be to try out each new idea that is suggested and considered worthy, in such a way that there will be a minimum of duplicate effort and a gradual process of eliminating those features found to be impracticable or too costly. Thus, through co-ordinating the experimental work which is now being done individually by the participating properties, it is believed that the work can be organized among them and among the manufacturers with whom they now deal separately. In addition to its other advantages, the cost to the companies would be considerably less than that for individual effort.

In brief, the program of the Presidents' Conference Committee is one of co-operative effort with every group interested in any way in the construction of railway cars. The committee does not contemplate going into the car building business; it is not seeking to destroy or restrict the field of activity of any car builder or car equipment manufacturer. It will strive to co-ordinate the efforts of these groups; to bring to a focus the minds of the engineers and technicians in these industries; to stimulate inventive ingenuity; to finance worthwhile experiments and to try out the experimental product to determine its practical usefulness.

It is estimated that the railway properties whose chief executives are members of the Presidents' Conference Committee represent over 60 per cent of the potential car buying power of this industry. It is unusual for a customer to match dollars with a manufacturer for the improvement of the manufacturer's product, but our need is so great that every railway company which has subscribed has done so realizing that if the effort is crowned with any measure of success, it will be repaid many fold the amount of its subscription in the lessened cost of new cars and the betterment of the car builders' product.

The subscribing companies have underwritten the work of the Presidents' Conference Committee for a period of three years. Research and experimental work takes time and it is believed that substantial results cannot be expected in a shorter interval. In order that there may be no misunderstanding, let me make it very clear that whatever advantages accrue from the work of the Presidents' Conference Committee will benefit the entire industry. This is not a little clique of railway companies seeking to gain a selfish advantage. Any railway company may participate in this effort upon the same general basis as those companies which have heretofore subscribed and their co-operation and cash will be most welcome.

In conclusion let me dwell upon one matter which is most important. I hope that the activities of the Presidents' Conference Committee will not deter any railway company from buying new equipment until the committee's work is completed. This would be a great mistake both from the standpoint of the railways in question and the industry as a whole. All progress cannot be wrapped up in the work of this committee. The committee hopes that our member companies will continue to buy cars as usual and, in fact, in larger quantities than heretofore. Many ideas can be tried out in this new equipment to the great advantage of all concerned; many valuable lessons can only be learned by actual experience. In exhorting other companies to go forward and purchase new equipment, may I call your attention to the fact that the company represented by the chairman of the Presidents' Conference Committee has had delivered to it within the last few days new interurban equipment in sufficient amount to enable it to operate its entire interurban property with cars none of which is over three years old, and that the company represented by the vice-chairman of the Presidents' Conference Committee has booked within the last few weeks the largest order in 1930 for electric railway equipment. A substantial number of new cars will be purchased within the next few months by other members of the Presidents' Conference Committee who recognize the futility of waiting until the work of the committee is completed.

The railway industry has suffered untold losses through indecision and delay in striking out boldly along the line of experimental research, which has proved to be the salvation of most of the successful industries of America. Of one thing only can we be certain, and that is that success never comes to him who stands still. We must keep moving; we must show the people of the United States that there is vitality and life in our business; we must buy new equipment—the best that can be designed at the time the purchase is made—relying upon the fact that inventive skill and engineering ingenuity can be relied upon to enable us to bring this equipment up to a reasonable standard of performance and at a reasonable cost.

Transportation Men Are

COMMUNITY BUILDERS

Definite obligations rest on the utility, the community and the regulatory body, said the author in addressing the American Association

By JOHN E. CURTISS
Chairman Nebraska State Railway Commission

WE ARE living in a day and age of tremendous rush and hurry. We are being carried along in an hysterical atmosphere of getting some place quickly, and of doing things rapidly.

Accordingly, I suggest that in the midst of this atmosphere of speed, it is well to gather together on occasions such as this, renew acquaintances, and discuss problems of common interest and importance. Surely from such a convention as this comes enthusiasm for the daily task.

I believe in optimism, in spite of Owen Wister's thought that common sense repudiates both optimism and pessimism. Someone said an optimist is a man who sees the light that isn't there, and a pessimist is a fool who is trying to blow it out. As between those two types, and we have them both in this great country, we all prefer to mingle with the man who attempts to see the light that perhaps isn't always there, but in spite of that fact, is struggling forward and on.

Quite naturally there are problems to be solved. Problems of government, problems of industry. They are frequently inter-related. Your industry has them, every industry has them, and in their solution we must have leadership. You have perhaps heard of the fellow who was standing along the curb when a great crowd dashed by. He watched it pass and then started out on the run to catch up with it. He pulled a fellow from the rear of the crowd and said: "Where's this crowd going?" The man replied, "I don't know." Again he rushed on and caught up with the crowd and pulled another man out of the rear of the crowd and said, "Where's this crowd going?" This man replied, "I don't know, I'm merely following it." The stranger said, "Well great heavens, man, I've got to find out where this crowd's going. I'm its leader."

John E. Curtiss

There is plenty of that kind of leadership today. The kind of leadership that involves following the crowd in the direction that it goes, rather than being out ahead pointing the direction in which it might properly go. Plenty of leadership that involves bringing together facts—but not too many, not enough to be embarrassing — mixing them together with a loud noise, indulging in mental gymnastics, a bit of legerdemain, some violent waving of the arms, and then, like finding the rabbit in the hat, reaching down in the can and pulling out the answer. We need men and women today who can see straight, think fast, and above all else, act honestly.

Indeed we live in a universe of law. This is true in the field of science, but it is just as true in the field of economics and of finance. Certain fixed results are sure to follow certain definite transactions. There is no financial escape from receivership when a company fails to earn fixed charges. There is no escape from embarrassment that follows, both to the utility and the community, when such a return is not paid on the value of the properties as will attract the necessary capital to provide for the proper development of the industry. There is no escape from unfortunate results that follow improper public relations, when the management, that is, the employer and employee, fail to understand the customer, and in a courteous manner render the highest type service possible.

And so, in the midst of constant change, we move forward. Accomplishment that a few years ago was declared impossible, is today accepted as commonplace. Probably the most important discovery made in our generation is that we know practically nothing about anything. Having discovered that, we place ourselves in the position to move forward, and no industry can be listed among the casualties so long as it understands that there are further problems yet to be solved and that they can be solved—will be solved—in the light of constantly changing conditions.

So I say, change is the order of the day, and I know of no industry more directly affected by this change than yours. And in that change, I conclude, comes the inspiration for the subject assigned me for brief discussion—"Public Responsibility in the Regulation of Competitive Industry."

Thirty years ago your industry had well nigh a complete monopoly in its field. You furnished the fastest, most certain, most satisfactory urban transportation. Indeed the opulent citizen owned a team of high-stepping horses and a fine rubber-tired buggy, but this was a luxury enjoyed only by the few, and even those few, together with the masses, depended on you for local transportation.

But we have pressed forward—at least, we hope it is forward. Today the horse and buggy have passed from the picture, and the smell of the exhaust and the roar of the cut-out are endured on every highway, as countless thousands of automobiles—there are more than 5,000,000 new cars sold each year—dash by. Thus your industry, once a complete natural monopoly, bringing to the people of our large communities one of the necessities of life, is now confronted with the keenest of competition from the privately operated automobile, and the publicly authorized taxi-cab. I know of no street railway company in the United States that has been able to avoid the acute prob-

Digitized by Google

lems resulting from this condition.

But with respect to your industry, we have passed through another cycle, and, whereas originally you were a natural monopoly, you now find yourself confronted with the keenest of competition. What is the public responsibility respecting regulation under such circumstances? It is a fundamental principle of regulation that charges authorized by the regulatory body shall be sufficient to pay operating expenses under economical and efficient management and in addition, a fair return upon the value of the property. This principle of course prevails whether the utility regulated be a competitive industry, or a complete monopoly. In other words, the end to be attained is the same in either instance. The means to the end may be different. It appears to be altogether proper that in reaching the end, a different attitude might properly be displayed by regulatory authority, where competition exists, than in the regulation of that utility which operates as a complete monopoly. The Supreme Court of the United States, in the Southwestern Bell Case, said: "It must never be forgotten that while the state may regulate with a view to enforcing reasonable rates and charges, it is not the owner of the property of public utility companies, and is not clothed with the general power of management incident to ownership."

It is always a matter of judgment as to just where management ends and regulation begins. Therefore, as competition reappears in a definite way, it seems that the heavy hand of regulation might be lifted, in degree at least. Competition itself makes for very definite regulation—indeed regulation of rates, service and operating expenses. To be specific, the competition which now confronts your industry, presents a very definite limit to the extent to which rates can be increased, else the point of diminishing return be reached. This very fact compels the most efficient and economical operation. Again this same competition impels you to render the very highest type service possible, that your patrons may not be lost to the competitor. It is a patent fact that officers involved in the management of a utility, have as deep-seated a desire for the successful operation of that utility, as those charged with the responsibility of regulation. Furthermore, they have, of necessity, a more comprehensive understanding of company problems and the possible methods of solution, particularly respecting the manner and methods of meeting competitive effort.

Accordingly, where a regulated industry is faced with actual and effective competition, governmental authority should seriously consider that fact in its regulatory effort. Such regulatory action as is necessary should be prompt. The local industry might easily "starve to death" if regulatory action be tedious and long delayed. And receiverships are always highly unfortunate, not only for the industry, but also for the community. Considerable latitude should be permitted the management in solving matters of service. In so far as it is possible, the management should be given wide discretion in either reducing or increasing service furnished, that competitive effort may be properly met. Again, choice should be permitted the management in reaching conclusions concerning matters largely managerial, such as wages and salaries paid, the proper allowance for advertising, the manner and form of service.

A sympathetic understanding between the utility, the regulatory body and the public served, is highly important and should always exist. The interest which each of these groups has in the problem is a common one. Quite naturally the public does not care to pay a rate higher than necessary, and yet the public has a very definite interest in a rate which is high enough to provide a service that is certain, satisfactory and modern. Such service can only be furnished when a return is paid in amount sufficient constantly to attract the capital necessary to keep the industry modernized. It is, of course, the legal obligation of a regulatory body to grant such a rate.

Confronted with competition, the importance of public relations cannot be over stressed. Whatever the attitude and action of the regulatory body may be, the industry finds that unfortunate public relations can be highly disastrous. In the main, this responsibility is yours. I regard it as your privilege and your obligation to acquaint the public with your problems—problems of finance and service matters. Your contact with the public is in the nature of partnership relationship, and we discover that it is not always a silent partnership, in so far as the public is concerned. Too much silence on your part in honestly explaining your problem to the community you serve may mean some unfortunate noise on their part at a very inopportune time.

I can't say that I am entirely sold on the philosophy which causes us to say, "The customer is always right." He may not be, and it may be your unfortunate obligation so to inform him. Rather would I say, give your patrons a square deal always, and then see that they know they are getting a square deal. Keep no secrets from them. Tell them the story of your problems honestly and constantly. Let them discover that your problem is a community problem. That such misfortunes as come to your industry are verily community misfortunes. Tell them the truth, the whole truth and nothing but the truth.

For indeed you are supplying a basic fundamental community need. The time has not yet arrived, nor does it appear to be imminent, when local transportation service for hire can be abandoned. We have observed the operation of street railways under receivership. In fact we have seen total abandonment of street railway service, temporarily, and in each instance we have seen all manner of business temporarily paralyzed as a result. Accordingly there must be real satisfaction to you in a knowledge of the fact that yours is a labor of service—that you are indeed community builders.

With no thought of being sentimental, I recall the story of the three stone layers. A stranger had been watching their effort from afar. He approached the first and inquired as to what he was doing. With a grunt he said, "I am working for $6 a day." To the second he directed the same query, and discouragedly the man replied, "I am laying stone." To the third man he addressed the same inquiry. For a moment he hesitated, his eyes flashed and his face beamed satisfaction as he said, "Sir, I am building a cathedral." I know of no industry, in spite of the change of the day, which can still say with such satisfaction, "Sir, we are building a community." Certainly in that effort, those charged with the public responsibility of regulation, recognizing a real competition which constantly challenges you, should be prompt and courageous in meeting that responsibility—should approach the problem with a sympathetic understanding that the best interests of the riding public, the community and the utility serving may be safeguarded.

Speeding Up Service

The speaker, addressing the American Association, told what has been done in San Francisco by scientific scheduling

By SAMUEL KAHN
President Market Street Railway,
San Francisco, Cal.

Samuel Kahn

EXPIRING franchises; a public somewhat uninformed, often misinformed; structures and equipment in good physical condition but not always embodying the last details of design to meet increasingly exacting passenger demands is a summary of the situation of the Market Street Railway when the present management took it over.

Just what does the public consider desirable in a 1930 street car ride? In following that quest, except for the date, we are treading the same trail followed by the horse car operator. He was required to furnish a speedy ride, at frequent and regular intervals, to carry the passenger in comfort—yes, even luxury—for that day and age. Was not the board seat of the horse car upholstered with its fine Brussels carpet a luxury in the days of plank sidewalks and mudhole streets?

From our experience in San Francisco it seems there can be little doubt about the public's demand for a quieter, smoother ride. The use of rubber shock pads between car body and bolsters; acoustical cloth under the car floor, under the trolley base, and under the air pump base have shown marked results with our own equipment—of all ages and designs.

Are new motors, quicker pick-up and quicker acceleration the only answers to the demand for greater speed without greater hazard? That these features are most desirable is beyond question, of course. But what of the street railway property that is not in a position to install such new equipment? Must it forego the essential benefits of more speed without more accidents?

It has been our experience that it need not. For instance, without change of motive equipment our speed has been increased from 9.4 m.p.h. four years ago to very nearly 11 m.p.h., day and night average, including all stops and delays except layovers. This has been done with a reduction of operating cost which materially helped in attaining an expense reduction which was greater than revenue decline last year.

Service to the public was not decreased, but rather increased 800,000 car-miles annually compared with four years ago. This car-mile increase served to absorb car-hour reductions sufficiently to obviate any reduction in operating force beyond the normal turnover, thus avoiding hardships to employees.

At the same time energy consumption has been reduced, and accidents substantially decreased.

UTILITY TAXATION

Advantages and disadvantages of gross receipts tax are set forth in a paper presented before the American Association

By M. D. LACK
Tax Counselor
California Taxpayers Association

IN CALIFORNIA, the tax situation reached a climax in 1910, when a constitutional amendment was adopted completely changing the revenue system of this state from the uniform *ad valorem* system for the support of both county and state to a separated system, setting up different sources of revenue for state and local purposes. By this separation, there was turned over exclusively to the state for its support those classes of properties such as public utilities, banks, insurance companies and the like which rather readily fell into a class whose activities were not circumscribed by county boundaries, leaving to the counties such properties as could be said to have a local situs.

The act of separation provided a tax measured by gross income, or gross receipts, for the former classes, with gross premium taxes for insurance companies, a capital stock tax for banks, and a franchise tax for business corporations; the tax to be collected from these classes was designated as strictly and exclusively a tax for state purposes, at least payable exclusively into the state treasury, and subject to its appropriation.

The state tax on these classes of taxpayers was made a tax in lieu of all other taxes and licenses of every kind, except payments agreed to be made to certain subdivisions for rights-of-way, franchises and the like, and neither the counties nor the cities were thereafter allowed to levy any tax against the property of these classes, when such property was used in the operation of their business, or in the production of the gross income which served as the measure of the state tax.

In return for the withdrawal from taxation from the counties of these classes of property, those subdivisions were no longer required to collect or to pay any tax for state purposes on their remaining properties, except that the act contained a

Digitized by Google

clause reserving the right, never yet brought into use, for the state, in case of an emergency, to levy an *ad valorem* tax on all classes of property, both state and local, equally, to take care of such emergencies.

Advantages and disadvantages of the California gross receipts tax might be summarized briefly as follows:

First, as to its advantages: It is certain, not subject to variation because of too much latitude for the exercise of individual judgments; it is simple of administration; it substitutes one central state authority with which to deal in the consideration and administration of the tax on operative property in lieu of a number of independent officials limited only by the number of cities and counties in which the property is operated.

Objections that may be urged against it are: Inequalities of tax burden between members of the same class of operators or utilities; tendency to remove the intelligent interest in and influence upon state expenditure programs by relieving the citizen of any direct tax for state purposes; creation of a tendency of both state and local subdivisions to transfer expenditures from one to the other, and, more serious still, for particular locally-supported activities to advocate additions to their income or revenues by persuading local citizens to join them in advocating that the state make a new or greater contribution to such activity on the theory that the local portion of it is too great by comparison, and thus securing their co-operation to bring about increased state contribution on the almost universally erroneous theory that it will reduce the local tax burden; the inclination to discontent between the two classes of taxpayers, growing out of the fact that the different methods of levy are not easily comparable as to equality, with the resultant tendency to conclude, on the part of one group, that the other is carrying less than a fair share of the load.

Interurban Revenues

Means of popularizing passenger service and attracting freight business discussed before the American Association

By D. W. PONTIUS
President Pacific Electric Railway,
Los Angeles, Calif.

REVENUE prospects of the future for the interurban electric railway are, to a great extent, what we make them. We must recognize the industry as a merchandising organization since transportation is the article for sale. There are certain groups of people who will buy our transportation because it fits their need; they realize its many advantages and are quick to see our faults. These form a large and important part of our patronage, and will stay with us so long as the service is satisfactory. There is another group who do not use interurban railway service, but who certainly should use it. At a much higher cost than rail service, they drive their automobiles to shop or to work. A large percentage of this group must sacrifice other things in order to do so. Efficient, dependable service with high-class, modern equipment will eventually bring a great part of them back to rail travel.

D. W. Pontius

Speed of service is an important point, and is demanded by present and prospective patrons. For this reason, we must encourage and to some extent participate in important grade separations; we must protect our private rights-of-way against further unreasonable opening of grade crossings, and endeavor to have eliminated all crossings now established when not essential.

Cleanliness of equipment, courtesy and attention of the platform men is an important feature that must be given constant attention to attract and hold business. Noise elimination is worth while, and this feature is now being given some much-needed consideration.

Retirement of obsolete equipment has been deferred perhaps too long in many cases. While this has been because of the necessity of keeping operating costs down to meet the revenue, undoubtedly this has been carried to extremes in some cases. There is a demand for first-class equipment that must be met.

Serious consideration must be given to the matter of fares. Our company has experimented with reduced fares extensively during the past three years. Fares are now on an unusually low basis, but we are convinced that the right step has been taken to increase the volume of traffic.

What applies to passenger traffic also applies, in a general way, to freight traffic, with the possible exception that probably the competition is more intense in connection with freight. The delivery of freight by trucks directly to the merchant, commonly called "store-door delivery," is, in my judgment, the strongest factor in this competition.

Retrieving of lost less-than-car-load freight traffic and promotion of new less-than-car-load business has been accomplished to a gratifying extent on the Pacific Electric Railway by the establishment of store-door pick-up and delivery. This service, although only begun in March, 1929, at 28 stations, has been extended to 51 stations; showed an increase of 12 per cent in the railway's less-than-car-load tonnage between March and September; and in the fifteen months since its establishment, less-than-car-load tonnage has increased 100 per cent. The railway's cost per ton for handling such freight at Los Angeles has been reduced about 18 per cent. The astonishing and very pleasing part of this is that of the business the "store-door" feature has brought in 95 per cent has been new accounts.

Advisory Council Activities Outlined at Banquet

Announcement made of selection of research director. Coffin prize presented to Youngstown Municipal Railway. Transportation problems discussed by A. W. Robertson

A SUMMARY of the activities of the Advisory Council of the American Electric Railway Association for the past year was given at a dinner in the Palace Hotel on the second night of the convention in San Francisco. Nearly a thousand delegates and guests filled the Palm Court and Rose Room. Other features of the evening were the presentation of the Coffin Award and an address by A. W. Robertson.

The meeting was opened by J. N. Shannahan, chairman of the Advisory Council. In speaking on the subject of its activities, Mr. Shannahan reviewed the five years since the Advisory Council of the American Electric Railway Association was organized under the chairmanship of B. C. Cobb of New York. Continuing, he said:

"The members of the Advisory Council represent a large proportion of the nearly six billions of capital invested in the business of providing local transportation service to American communities. The idea in the minds of those responsible for the organization of the Council was that in bringing together these men of large affairs, of wide experience and broad vision, their collective judgment and advice would be of the greatest help in working out the many baffling problems with which the industry has been confronted for a decade. These problems have been materially complicated by the necessity for keeping pace with the growing requirements of modern communities, while at the same time attempting to improve and modernize our facilities to meet new conceptions and new standards of public transportation service on the part of the people whom we serve.

"The men responsible for meeting the demands of the people for adequate, safe and speedy local transportation are alive to their responsibilities, and anxious to so satisfy the riding public by the character of the service they furnish that everyone will acknowledge that such service is in fact an essential, yes, indispensable, need of the community; service of such a character that the car rider will gladly pay such a fare as will enable these companies to compete in the money markets of the world for the funds so necessary to provide these extensions and betterments in which the riding public has so vital an interest.

J. N. Shannahan,
Chairman Advisory Council

"There is no mystery regarding the cause of the change in the public's conception of what it is willing to consider satisfactory transportation service. The rapid and remarkable development of the automobile created new standards of speed, convenience, and even luxury in transportation. This threatened to make obsolete much of the equipment and other facilities of our companies. At the same time, rapidly rising costs of materials and labor made the most rigid economy imperative and prohibited sweeping replacements of physical property.

"But while the public approved the expenditure of vast sums for the construction of streets and highways, without which the rapid development of the automobile would have been impossible, it failed to permit the modernization of public transportation facilities by insisting upon the retention of obsolete franchises, obsolete fare schedules, and obsolete taxes and imposts of various kinds. These have been the basic obstacles to the modernization of public transportation facilities. They have had much the same effect in curtailing the improvement and extension of community transportation as a failure to build roads and to improve streets would have had upon the development of the automobile. As a consequence, public patronage of transportation facilities which came to be looked upon as obsolete and out of date, was rapidly curtailed to merely necessity riding.

"Because the people as a whole agreed to assume the cost of adequate roads and highways, they have made possible the development of the automobile as we know it today and have permitted the automotive business to grow into one of our largest and most important industries. It has become a very important factor in our present industrial structure, and nothing should be done to injure it. When the public understands that obsolete methods of dealing with its local transportation problems constitute the primary cause of many of the difficulties faced by cities of various sizes throughout the country, the way will have been opened to that rapid development and improvement of community transportation facilities which is so greatly needed today.

"For the past four or five years there has been considerable activity on the part of individual operating companies and manufacturers in developing improved type of street cars, suitable for modern traffic conditions and designed to meet the transportation standards of a public whose tastes and transportation standards have been so materially affected by the convenience and luxury of the automobile. The Advisory Council, sensing the need for co-ordination of individual activity in meeting this common problem, at the last convention authorized the organization of a special committee

Digitized by Google

of executives under the chairmanship of Dr. Thomas Conway, Jr. That work has been consistently pressed forward since that time. A careful analysis of the whole car and equipment problem in the industry was necessary before a definite plan could be developed. This, however, has been done and as a result the electric railways of the country are about to launch a co-operative program of research and development, which has long been needed and which, if successful, will be a most important forward step in meeting one of our most acute problems.

"Dr. Conway's committee, after a careful study of the problem, decided that in the selection of a chief engineer to have immediate charge of the work of research and development, it should choose not necessarily a man familiar with the construction of cars nor even with the operation of them, but rather an experienced and competent engineering executive — a man who has demonstrated his capacity to conduct research of large projects and bring them to a successful issue. The committee believes it has found the right man for this work in C. F. Hirshfeld of Detroit, Mich. Mr. Hirshfeld has been for years head of the research department of the Detroit Edison Company. He has had an extended experience in carrying on research work for that company, for the National Electric Light Association, and for other important interests. His is a great task and can only be brought to success with the cordial support and help of all those intimately concerned in the building and operation of the electric car.

"The Advisory Council commends this project to the industry and to the public. Recognizing that there are many street cars in operation today that are badly in need of replacement, it feels confident that the development of designs to meet modern traffic conditions and which will at the same time eliminate much of the popular impression that the street car is an obsolete means of transportation will prove entirely feasible. A group of important railways and large manufacturing companies are backing this project, and it is confidently expected that there will in a relatively short period be available improved types of cars which will make replacements of many existing cars economically practicable."

Mr. Shannahan then introduced the toastmaster of the evening, President Paul Shoup, who again welcomed the delegates from all over the country to the convention and to San Francisco. President Shoup read the report of the committee on the Charles A. Coffin Foundation Award and presented to C. S. McCalla, president and general manager Youngstown Municipal Railway, the Charles A. Coffin Medal and the accompanying check for $1,000.

The address of the evening was made by A. W. Robertson, chairman of the board Westinghouse Electric & Manufacturing Company. Mr. Robertson offered as one step in the solution of the urban transportation problem, the establishment of "transportation districts" for a given community. He urged a closer co-ordination and co-operation between the railways and the various official factions of the area served for the purpose of obtaining better operating conditions under revised franchises and adequate fare structures.

Mr. Robertson further stated that mass transportation is as essential to public service as water, gas, telephone, or any of the other common modern conveniences. For more than a generation street railways have furnished this transportation to our cities. The development of the automobile has reduced the earnings of the transportation companies, but the need of some form of mass transportation is as real as ever. If it were not for the congestion on our streets and the reduction in the number of riders on our street cars, this form of surface transportation might well compare in speed, comfort and safety with any which the world has known, but due to the congested streets and reduced revenue under which the street railway operates, it has to do without many things which the transportation company and the public might otherwise consider necessary.

Many things have been done and are being done to assist the transportation companies in rendering service, but real forward steps cannot be successfully undertaken until the business men, the people at large, and the civic authorities realize fully that the handling of huge masses of passengers in our municipalities is a very complex community problem, and whole-heartedly and constructively co-operate with the local transportation company in solving it. Traffic congestion in our cities not only causes loss and inefficiency to the street car company but also represents a gigantic economic waste to the community. Every city is suffering from its blight. If we can solve the traffic congestion in any acceptable way we solve our mass transportation problems at the same time.

American Executive Committee Breakfast Meeting

REPORTS of several committees of the American Association were presented briefly at a breakfast meeting of the executive committee held on Monday at the Fairmont Hotel. G. C. Hecker, general secretary, presented the report of the publications committee, suggesting that renewed consideration be given to the publishing policy of the association magazine, *Aera*. F. R. Coates told of the gratifying increase in the number of state and sectional associations which have joined the American Association. An outline of the insurance situation was presented by F. L. Butler in the absence of the committee chairman. Leslie Vickers, economist, spoke briefly concerning the work of the committee on taxation. Arrangements for the convention were commented upon briefly by W. V. Hill, who introduced the chairmen of the various local committees which were instrumental in the preparation for the meeting. It was decided, on the suggestion of J. H. Hanna, that a committee should be appointed to study the problem presented by changing conditions in the industry with a view to making corresponding changes in the organization of the association.

W. W. Wysor, president of the Engineering Association, E. H. Reed, president of the Accountants Association and J. H. Handlon, represening the president of the Claims Association, spoke briefly concerning the work of these affiliated bodies. It was decided that the next meeting of the executive committee should be held sometime in August at New York City.

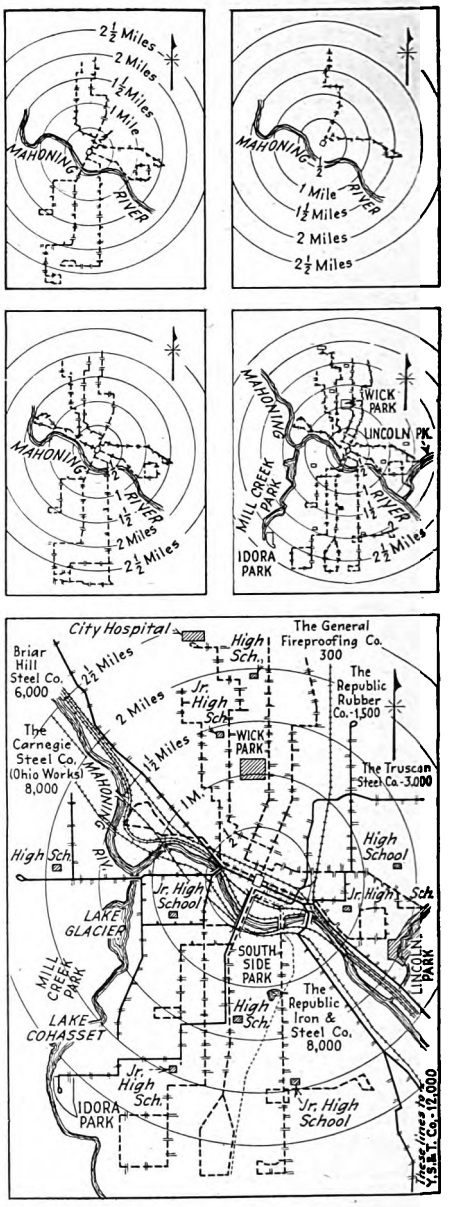
COFFIN AWARD Won by *Youngstown*

Modernization of equipment, plant and operating practices, co-ordination of rail and bus services, satisfactory public relations, and co-operation of and with employees mark year of progress. Briefs submitted by six contestants summarized

IN VIEW of its skill in successfully fitting the character and amount of service to the needs of the public and in effectively selling that service to the public, the Charles A. Coffin Prize for 1930 has been awarded to the Youngstown Municipal Railway, Youngstown, Ohio. Five other companies, which submitted a record of their accomplishments during 1929, made noteworthy contributions to the development of the electric railway industry. They are the Cleveland Railway, Cleveland, Ohio; Community Traction Company, Toledo, Ohio; Union Street Railway, New Bedford, Mass.; Eastern Texas Electric Company, Beaumont, Tex., and El Paso Electric Company, El Paso, Tex.

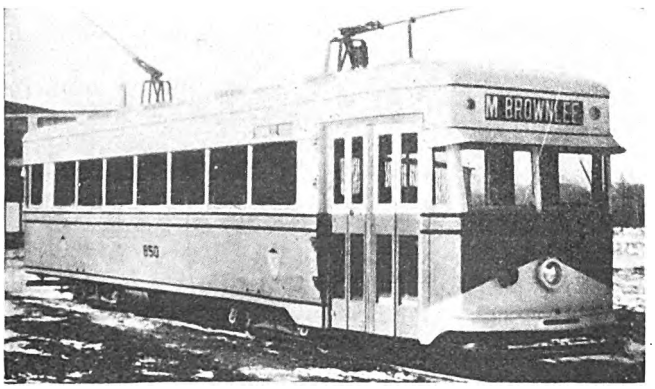
Six principal factors were considered in making the award: more riders and more revenue; friendly public; lower costs and increased reliability of service; increased safety for riders, employees and the public; co-operation between management and employees; and financial accomplishments. Seven electric railways have received this award since its establishment: the Chicago North Shore and Milwaukee Railroad, in 1923; the Northern Texas Traction Company, in 1924; the Pittsburgh Railways, in 1925; the Pennsylvania-Ohio Electric Company, in 1926; the Grand Rapids Railroad, in 1927; the Virginia Electric & Power Company, in 1928, and the Chicago, South Shore & South Bend R.R. in 1929.



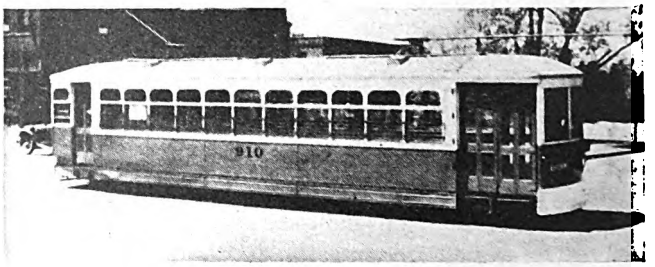
Youngstown is now served by an efficiently co-ordinated system of car and bus routes. The four smaller drawings represent bus lines in 1922, 1924, 1928 and 1929. The larger one the complete system now operated

New Franchise Assures Continued Success in Youngstown

FULL realization of an extensive program of modernization which included a new franchise, new cars and unbroken progress in the standardization of operating methods, materials and economies was the contribution of the Youngstown Municipal Railway, Youngstown, Ohio, to "the development of electric railway transportation for the convenience of the public and the benefit of the industry." This privately owned and operated utility is a part of the Penn-Ohio System which serves the city of Youngstown and suburban territory with an aggregate population of 216,000. Complete co-ordination of street car and bus services has been



A complete program of rolling stock modernization



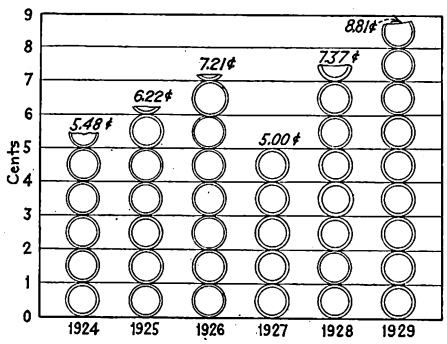
Digitized by Google

Municipal Railway

effected in this territory, the two being used as equivalent vehicles in equivalent service. On this property the bus is not parallel or supplementary.

The new franchise, made final by act of the city government on May 22, 1929, was the outstanding accomplishment of the Youngstown Municipal Railway. The negotiations, in open forum, with the leaders of business, finance and industry of the city resulted in a franchise which not only provides for flexible rate of fares, relief from unnecessary burdens, assurance from competition and genuine co-operation between the city and company in efficiently serving the traveling public, but also provides an arrangement financially satisfactory to the company and affords a basis on which it is justified in spending money for extending and improving its service.

The salient features of the franchise are: complete freedom from all obligations for construction of paving, or paving foundations, except such additional foundations as are necessitated by tracks; complete relief from any obligations for repair of pavement, except repairs actually occasioned by any act of the company; complete relief from all minor exactions such as sprinkling, street sweeping and cleaning, and burdens of this character. The franchise acknowledges the company's right to operate without cost or consideration over all bridges and grade separation viaducts now built and in case of rebuilding said bridges or viaducts, or the construction of new ones, at only such cost as the construction of tracks may add to the cost of the bridges or viaducts; deprives the city of any control over service or fares of the company in case the city should suffer, permit or aid competition with the company, with the exception of existing street railway and taxicab companies and provides that the cost of city control, including salary and expenses of street railway commissioner and his assistants, shall be paid by the city instead of by the company as heretofore.



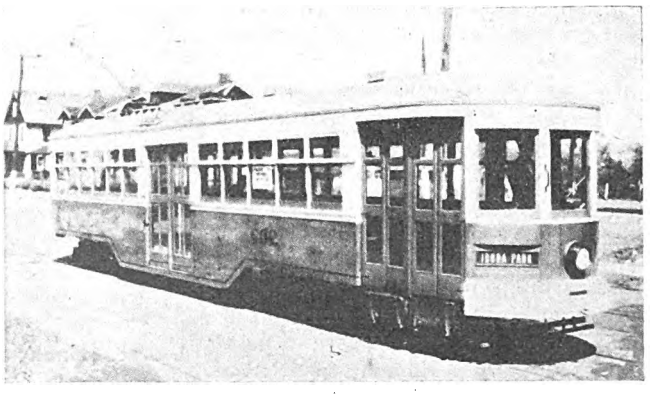
Growth in net revenue in cents per mile before taxes and depreciation

An initial rate of fare of 10 cents cash, six tickets for 50 cents is allowed with provision for increasing and decreasing fares automatically, but with further provision that such sliding scale of fares shall not be impaired by fares other than the sliding scale placed in effect by agreement between the city and the company. Finally, the company shall receive after taxes and depreciation, 6 per cent return on its original capital value and 7 per cent return on all additional capital value, and further, the company shall participate in all excess fares over the rate stipulated to the extent of one-half after a surplus of $100,000 has been accumulated.

During 1929 the Youngstown Municipal Railway acquired thirteen of the most modern cars, of extremely low weight per seated passenger, high-speed motors, double-reduction drive and automatic foot controls. Thus it completed a program under which there does not remain a single street car in use on the property purchased prior to 1917 which has not been fully rebuilt.

The speed of the new cars means cash savings in actual service. The thirteen new cars purchased in 1929 develop an acceleration of 3½ m.p.h.p.s., and unusual deceleration. Advantage is taken of this improved acceleration and braking ability on the main trunk line extending the full length of the city from the industrial plants at Mosier on the west

has been carried out by the Youngstown Municipal Railway



Digitized by Google

side to those of Campbell, on the east side. Through the use of this new equipment 237 car-hours per day, or 6,665 car-hours per year, are saved in giving equivalent service. The actual economy realized through the substitution of this modern equipment is approximated at $80,000 per year.

The net earnings of the company available for taxes and depreciation and after the payment of operating expenses, including the purchase of power, have been steadily on the increase during the past seven years. In 1923 the net income was $250,967 and in 1929, $513,369. This increase is attributed to the constant attention to the popularizing of electric railway service in Youngstown and meeting the competition of private automobiles by improvement in character, speed, comfort, convenience and general attractiveness of the service rendered and by application of merchandising methods in selling this service.

Economies in operation have been effected as the result of original ideas and the application of ideas orginating with others so that revenue per employee has increased, unit revenue has increased, and unit expense has diminished. The largest net revenue in the history of the company resulted in the year 1929. Car and bus changes were reduced, the number of pull-ins cut and a variety of methods and practices resulting in satisfactory service to the public and improved financial returns have been adopted.

The Youngstown Municipal Railway gives evidence of its faith in the continued success of its operations in its plan for the continuance of further development. The budget for 1930 contemplates an expenditure of $543,400. This expenditure is all voluntary and, on a property of this size, manifests the faith the management of the company has, not only in the industry in general, but, under the present conditions, of its future in Youngstown.

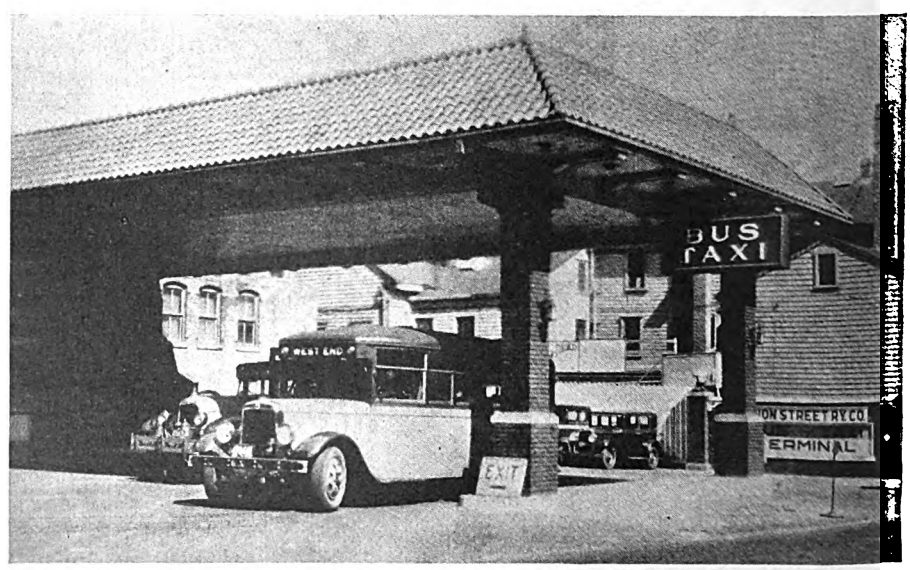
New cars purchased by the Union Street Railway are modern in appearance and equipment

Car, Bus and Taxicab Services Co-ordinated at New Bedford

CONTINUED success in the operation of an old, well-established railway is reflected in the claims made for the 1930 Coffin Award by the Union Street Railway, New Bedford, Mass. Aside from operating the railways more efficiently and economically, the company has benefited from the increased gross revenue obtained from taxicab and bus operations. While these new forms of transportation have been added, operating expenses have decreased markedly.

Comparison of revenues between 1928 and 1929 are reasonable and fair as there has been no refinancing of the company since the last issue of common stock in 1918 and there has been no increase in fares since May, 1927. The story of accomplishments reflecting the results of operating effort during 1929 are as follows: the gross earnings from operations in 1929 were $1,283,221 as compared with $1,286,624 in the previous year. This is a decrease of only 0.2 per cent, so it is fair to state that the gross earnings for the past two years were practically constant; during the same period the operating expenses decreased 3.9 per cent, or from $1,165,964 in 1928 to $1,120,118 in 1929; the operating profit after depreciation increased 35.1 per cent, an increase of $42,442; the depreciation rates in 1929 were not decreased over those used in 1928; the net operating profit, after interest and taxes, increased 71.9 per cent, or from $50,733 in 1928 to $87,223 in 1929 and the credit balance of the company was increased 6.2 per cent.

For a number of years the Union Street Railway has maintained a traffic department which devotes the greater part of its time to analyzing riding requirements and making time-tables to meet the needs of the public. Not only has this given service where, when and as required, but it has been the means of saving thousands of dollars by eliminating unnecessary service. During 1929 this department functioned in such a way as to make it possible for the company properly to segregate its various classes of service. The following figures show the results of this work: 18,108 miles of bus, trolley and taxi operation were saved over the previous year's operation, or 0.1 per cent; receipts per car-hour increased from $3.46 to $3.47, and receipts per car-mile from 40.17 cents to 41.04 cents. The decreased mileage



A large, centrally located bus and taxi terminal has resulted in more efficient operation of the two services

Digitized by Google

was due to increased schedule speeds, service adjustments and bus co-ordination, resulting in increased receipts per car-hour and per car-mile.

Practically all existing rolling stock has been rebuilt and remodeled into modern one-man cars. Modern de luxe interurban cars have been put in operation on the line between New Bedford and Fall River. The entire complement of older street cars has been kept in excellent condition and a series of new cars were purchased in 1918, in 1923 and in 1929. The latter cars are of the most modern type equipped for one-man or two-men operation. They resemble the automobile to some extent, the body being painted to produce the streamline effect. The cars provide seats for 44 passengers, and all seats are covered with leather upholstery. All mechanical equipment is automatic and is concealed from view. The windows are especially wide so that regardless of where a passenger is sitting he has a clear view outside. The cars weigh 17½ tons and are equipped with four 35-hp. motors. Fast accelerating and braking rates are attained.

An example of proper co-ordination between street car and bus is found in the service between New Bedford and Fall River, Mass., and Providence, R. I. The service, inaugurated in 1925 by the Union Street Railway, competed with the company's existing trolley lines that operated between New Bedford and Fall River, Mass. The rate of the fare charged on the buses is 50 cents between New Bedford and Fall River, and $1 between New Bedford and Providence. The motor trip between New Bedford and Fall River takes 40 minutes. The trolley fare for a ride between New Bedford and Fall River is 30 cents, and the running time 50 minutes. In these two services, patrons have the choice of the speed and rate of fare they desire. No local stops are made by the bus, while the street car accommodates all local patronage en route. The result of this co-ordinated service shows that the combined gross revenue of both trolley and bus operations has more than made up for the loss of trolley revenue. Decreased trolley patronage has made it possible to effect a decrease in street car expenses.

During 1929 the company purchased a large, centrally located gasoline station, which, in addition to having a large amount of land, had a permanent canopy extending over most of its property. It was possible to park several buses at a time under this canopy, and to accommodate the entire taxicab fleet on private property in front of this taxi and bus terminal.

The taxicab service performed by this company is based on its reputation for reliable, convenient and comfortable service. Taxicab fares are based on flat rates because of independent competition, but the company has been able to do a good business in spite of the fact that other long established companies charge rates nearly one-half of what the railway charges. Telephones are located throughout the city and have been used for a number of years by the railway inspectors and starters. By using these telephones, the taxicab drivers eliminate a great deal of dead mileage.

More Passengers and Fewer Accidents at El Paso

Timely advertising has resulted in increased riding in El Paso

HANDLING passengers of whom more than half are foreign born, serving two countries with dissimiliar laws and customs and increasing passengers and revenue, marked the accomplishments of the El Paso Electric Company for the year 1929. This company serves the transportation needs of El Paso, Tex., and Juarez, Mexico, as well as a large U. S. Cavalry Post at Fort Bliss, the municipal airport and a new industrial center.

THERE are approximately 141,900 people in this service area which are served by 80 passenger street cars, four work cars and fourteen buses, operating on 48.52 miles of equivalent single track. No rail extensions were made during the year, but additional co-ordinated bus routes were established to supplement street car service. The principal factors contributing to improvements are measures that have been responsible for both increased efficiency and added economy.

The operating revenue in 1929 was greater than for any year since 1921 when El Paso's normal population was augmented by some 60,000 or 75,000 soldiers concentrated for demobilization following the World War. The gain in gross receipts was $60,988 or 7.2 per cent above receipt for 1928. Street cars and buses carried over a million more revenue passengers in 1929, an increase of 5.82 per cent over the previous year.

Broadly speaking, the marked improvement in earnings made has been

Digitized by Google

brought about by the speeding up of service, through the intensive sales efforts carried on throughout the year and by accurately fitting service to conditions. Speeding up of service was the result of faster schedules and closer supervision. A considerable portion of the rolling stock is new while the older equipment has been completely remodeled and includes the latest improvements in operating comfort and convenient details.

Merchandising plans carried out fully have embraced all the popular practices as well as many that are novel and which have been used in El Paso and Juarez with unusual success. The operators have been trained in courtesy, in safety, and in skillful salesmanship. Sales efforts have included house-to-house canvassing backed by the liberal use of newspaper advertising, pamphlets, inside car cards and various other mediums. The methods used to sell car rides incorporate credit sales of ticket books, department store cards, special service and other novel ideas.

One of the outstanding accomplishments of the El Paso Electric Company for 1929 was a further reduction in accident costs. Within the five-year period from 1921 to 1926 inclusive, this company effected a reduction in accidents equivalent to 76 per cent, as well as making other remarkable improvements in safety. In 1921 the company was experiencing 8.83 accidents per 10,000 car-miles which was reduced to 1.42 accidents per 10,000 car-miles in 1926. This low ratio was maintained until 1929 when a further substantial improvement was made with a further reduction of 68 per cent in the settlement of claims, suits and judgments. The amount paid in settlements during 1928 was $29,374 as against $10,402 for 1929. Safety contests, first aid demonstrations, honor roll systems, safety banquets and similar measures were used to maintain interest in accident reduction.

An excellent record for economy and efficiency in the maintenance of equipment has been made in the past and further carried on in 1929. Modern methods, original devices, improved practices and better facilities together with a highly skilled personnel have all contributed in this phase of operation. Particular attention has been paid in the recent past to the establishment of an upholstery department and the adoption of a centralized system for reclaiming scrapped material.

Large savings are reflected in improved construction methods as well as better maintenance practices. Original plans for track paving and similar measures have produced improved operating results at reduced costs. After a careful study of the different types of tracks and construction the El Paso Electric Company has standardized on a 90-lb. A rail, steel ties, crushed stone ballast and concrete pavement.

Concentration upon the concrete pavement is a measure of economy practiced in construction worthy of note. This, in general, is one-course construction, but in heavy traffic intersections or under other special conditions it is two-course construction, consisting of a rather lean base (1:3:6) and a granolithic surface of a much richer mix resembling a good sidewalk coping. For both, the company insists on a dry mix of good workable consistency. It has trained its crews to the point where the costs are way below that of the local paving companies and in addition it gains the most desirable end, that of having the entire job under its control.

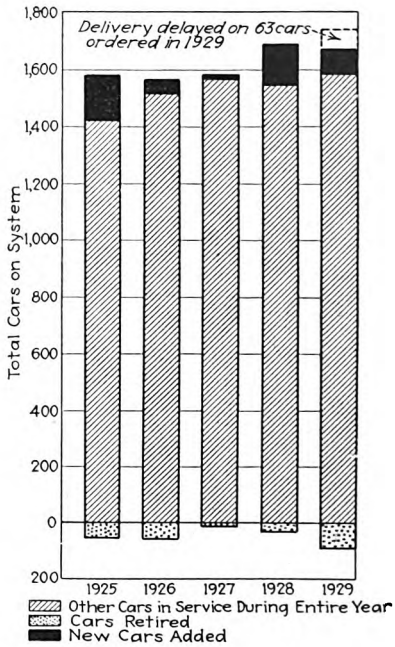
The construction program for 1929 called for a larger investment than that annually required for the past sixteen years. It included construction of a new power plant, a substation, a connecting transmission system and installation of equipment in the old power station necessary for the utilization of natural gas as fuel. The company also built a new reinforced concrete and steel bridge over the Rio Grande River to replace the old wooden structure.

In order to retire existing floating indebtedness and to finance the major portion of the construction program, $4,000,000 of 5 per cent bonds were issued in addition to the bonds already outstanding under a mortgage dated June 1, 1925. The bonds were sold to a syndicate of brokers for offering at a price of $95 to yield 5.40 per cent to maturity. The net to the company was $91. After discount and other expenses incidental to the issue, the net cost of this new money to the company was approximately 6½ per cent. This financing reflects a rather outstanding achievement since it was necessary to float this issue in June during a highly speculative market.

Cleveland Railway Pioneers with New Cars and Maintenance Equipment

FOREMOST in the Cleveland Railway's 1929 program to popularize electric railway service and to meet the competition of private automobiles was the purchase of 100 new single multiple unit control type of cars, following a purchase in 1928 of 50 new single-unit and 28 articulated trains. These 206 cars have given to the Cleveland public considerable convenience and generally attractive service. They have been designed for high rates of acceleration and therefore will function well in securing high speeds when schedules are revised as a result of transportation research.

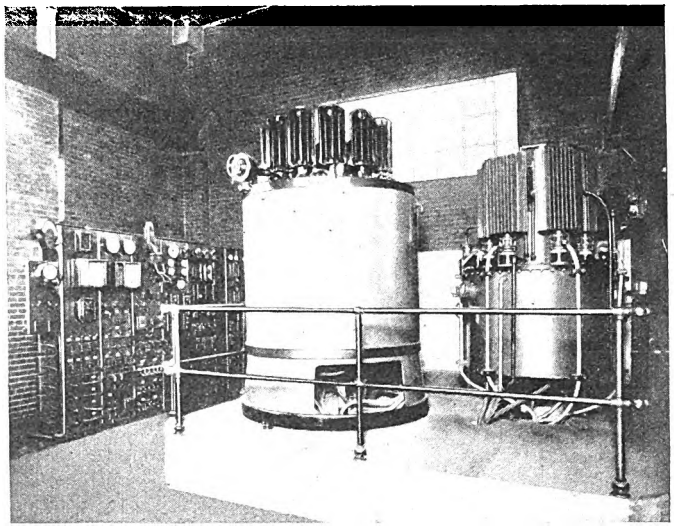
Cleveland pioneered the aluminum car for street railway use. It was built to demonstrate the durability of this material and that lightness could be obtained without sacrificing strength. The substitution of aluminum for steel reduced the weight of the car 12,900 lb., or 29.9 per cent. Its weight is 30,300 lb. as compared with 43,200 lb. Actual power saving per car-mile is 15.3 per cent. Aluminum was substituted for steel wherever possible. The superstructure, conduits, fenders, ventilators, couplers, trucks, compressors,



The purchase of new cars is a continuous policy in Cleveland

Digitized by Google

Interior view of aluminum car with which Cleveland Railway has been experimenting



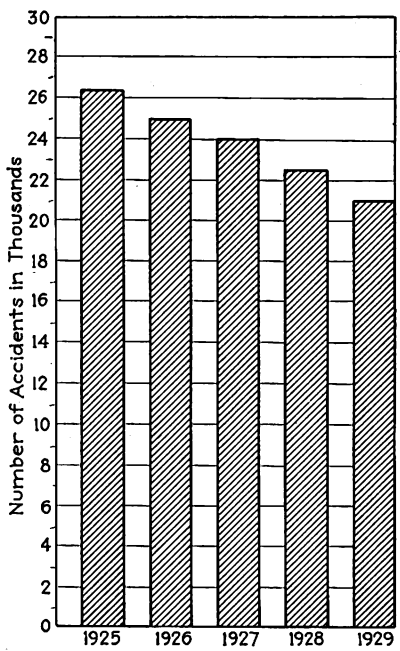
The Cleveland Railway is studying the mercury arc rectifier and its application to service conditions

brake cylinders, brake rods and bolsters were made of aluminum. Wheels, axles and motors, with the exception of bearing housings, remained steel. This car was put into regular service Jan. 1, 1927, and has been in constant use since that time, operating an average of 2,200 miles per month.

Recognizing the need for coordination of all transit facilities in the city of Cleveland and surrounding territory, the Cleveland Railway has co-operated with the rapid transit interests in developing a terminal plan around the public square. This plan will focus the principal industrial, business and banking activities at this central point and will provide an easy interchange of passenger traffic between main railroad trunk lines, the rapid transit system, the surface rail and bus system, taxicab service, private automobiles and pedestrians.

More riders and more revenue were obtained when the Cleveland Railway made a profitable substitution of a motor coach line for an unprofitable street car line. Flexibility of the motor coach not only permitted necessary rail abandonment, but also secured service extensions. This new express service from Cleveland Heights to Public Square, a distance of 7.92 miles, is attracting the previous user of the privately owned automobile. It is making a steady customer of a former occasional user of the Cleveland Railway Transportation Service. The earnings under the fare of 25 cents are averaging 30 cents per mile.

With the incentive to produce the very best service at the lowest possible fare and the lowest cost, the Cleveland Railway has continuously developed new equipment, machinery and methods. The automatic substation and remote control system first applied to metropolitan service in Cleveland has resulted in a continuous system power supply which has experienced no interruption on the system as a whole in over five years. This company not only conceived the idea of applying the automatic substation to metropolitan operation but actually specified and assisted in developing the equipment necessary for the operation and control. In the early development of a 60-cycle a.c. transmission system, there was no synchronous converter equipment available, and realizing the advantages of purchasing power from the existing 60-cycle central station rather than building a 25-cycle plant, the Cleveland Railway, after extensive investigation, undertook to design the first large capacity unit, namely, the 1,500-kw. size. With this machine they blazed the path for large capacity with 60 cycles. While it was a success from the start, the company has continued to improve its operation down to date.



Accidents are showing a steady decline in Cleveland

The possibility of applying the mercury arc rectifier to a metropolitan 600-volt power system has been carefully studied by the Cleveland Railway, and experimental installations have been made in co-operation with manufacturing companies. These experiments have included the application of automatic control, the super-imposition of remote supervisory control and the necessary changes to adapt the device to parallel operation with a synchronous converter in the same plant, and the development of means to overcome interference with telephone circuits. The original experimental units have now been replaced by the most recent development, consisting of a 500 and 1,000-kw. unit. As a result of these experiments, it is expected to ascertain how the mercury arc rectifier can be best applied to service conditions.

The Cleveland Railway has been a leader in the development of labor-saving machinery and equipment designed to reduce cost of operation. The shop, tracks and maintenance departments have all benefited from this progressive policy of developing new devices.

The Cleveland Railway has proceeded with its own safety program from an analytical standpoint to de-

Digitized by Google

termine the basic causes of accidents, having in mind the establishment of safe practices without affecting speed Reduction of costs of injuries and damages has been the result of this study. In addition to this encouraging financial success, the extensive first aid instruction has caused the employee to sense the economic aspects of accident prevention. All transportation accidents show a study. In addition to this encouraglast five years.

Because it recognizes that profitable public relations depend largely upon the trainmen, the Cleveland Railway has centralized all industrial relation functions such as job analysis, selection and training of employees, accident prevention, public relation activities, suggestion systems, insurance and pension plans and welfare activities. This unusual centralization has resulted in an organized program of strengthening the trainmen's morale and inaugurating an intensive sales effort as a specialized activity of the company's personnel department.

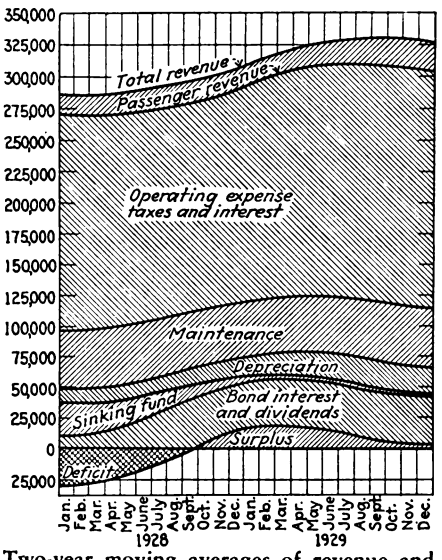
Other results have been improved employee relations, and the process of the employment interview, together with its public relation phase; standardized grading of applicants; standardized ability tests, and subsequent training. The aim is the training of specialized salesmen to enter a highly competitive market in which the company has at stake a million sales per day.

Services Modernized and Co-ordinated in Toledo

SUCCESSFUL co-ordination of street car and bus operations, permitting the extension and improvement of service with little new capital, is submitted by the Community Traction Company as its outstanding accomplishment in 1929. An increase in riding of 5.25 per cent and of passenger revenue of 5.35 per cent in contrast to an increase in average of employment of only 2 per cent was gained on the basis of better service because there was no change in company fares and the present franchise permits no opportunity for trials of special ride-selling fares. That the company kept pace with this increased patronage is shown by the fact that there were nearly 1,000,000 more service-miles operated in 1929 than in the previous year, an increase of 11.62 per cent.

A terminal-to-terminal speed increase of 22 per cent was made possible largely by rescheduling various car lines after increasing the horsepower per car from 70 to 140 and by rearranging the stops. This result was obtained during the greatest street reconstruction program in the history of Toledo.

Bus service was developed to a high degree with special attention to peak-hour industrial short-cut routes, schools, replacement of steam shop trains, door-to-door delivery of night workers, extensions to outside industries, guaranteed operation for suburbs and chartered service.



Two-year moving averages of revenue and expenses show progress in Toledo

The reduction in railway route mileage and the remarkable rise in motorbus routes does not in any way indicate the early demise of Toledo's street cars. Proper coordination of these services has strengthened the operation. The trunk line street car routes, particularly on the wide improved streets, have been rejuvenated to carry still heavier loads. On the other hand, the bus has been used to replace the slow, weak-traffic, single-track routes of narrow streets, to take up the loads of the non-competitive portions of old duplicative routes, to develop new crosstown routes for expanding and relocated industries, to serve as feeders and "owls" of street car routes and finally to create a variety of chartered daily and casual services made possible by the flexibility of the bus.

Traffic studies and new scheduling practices have resulted in better use of mileage. Former practice provided a certain number of base vehicles to run from 5 a.m. to midnight. Additional service was provided during the intervals, from 5 a.m. to 9 a.m. and from 3 p.m. to 7 p.m. This arrangement gave too much service just before and after the peak, yet not enough service at the peak.

A definite humanizing of employee relations has been continued during 1929. Comfortable working quarters and shopmen's uniforms have been supplied. Athletic and musical organizations have been fostered and economic matters, such as the treatment of veteran employees, of the superannuated, sick and injured, and of the families of deceased workers, have been furthered. All this work was done with the restriction imposed by the service and cost operation of a union property.

Two renewals of wage agreements have been made—the first in June, 1928, with no changes in wages except adjustments for some shopmen, and the second in June, 1929, when trainmen's wages were raised 2 cents an hour plus 1 cent an hour additional to each man who has a "No Accident" month. Further evidences of proper relations between management and employees are found in the growth of one-man operation and the selection and retraining of electric operators for bus service.

All financing, with the exception of the five-year way reconstruction program, has been done out of the earnings and on unsecured loans from local bankers. One of the most notable examples has been the fact that the extensive motor bus development of Toledo has been built up without any new capital. Buses are acquired on a rental basis, involving monthly payments over a period of years. Thus the buses can and do, in their entirety pay for themselves directly out of their earnings. The only buses that appear in "plant accounts" are those taken from the independents. Profits from operations which comprise any money remaining after expenses and rentals are assigned to "general surplus." To this "general surplus" will also be assigned whatever turn-in value the buses may have.

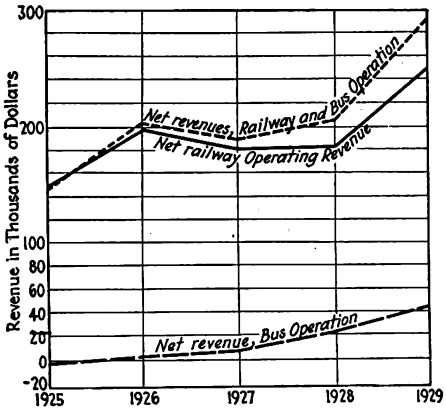
Gross and Net Increased by Eastern Texas Electric Company

POSITIVE evidence of progress, written in terms of greater gross and net revenue, is given by the Eastern Texas Electric Company in a statement of accomplishments for 1929. Serving a total population of approximately 116,000, this company furnishes street car and bus transportation in the cities of Beaumont and Port Arthur, Tex., and operates an interurban car line between them.

Local transportation has been furnished by the Eastern Texas Electric Company in Beaumont since 1912 and interurban service to Port Arthur since 1913. The successful operation of these systems, together with their progressive attitude in civic affairs, has built for them an enviable reputation. This reputation led the citizens and business interests of Port Arthur, acting through its city administration to petition the Eastern Texas Electric Company to take over the failing system in that city.

After a very thorough investigation of the situation, this property was purchased and a program of complete rehabilitation put into effect. Within the short course of slightly more than a year a property with worn out tracks, patched-up network for overhead, junk for rolling stock and ill-will instead of good-will was rendering a modern service and was put on a sound operating basis. The results speak for themselves. Gross revenues were increased from $6,023 in February, 1928, the first full month of operation, to $21,397 in December, 1929. In this latter year the property made a net earning of 16.8 per cent on the capital invested.

Accomplishments on the property as a whole, considering the two local services and the interurban line, can further be told with more figures on net revenue. Operating revenues for the year 1929 have been increased 18.8 per cent over the preceding year, while operating expenses only increased 8.2 per cent. Net revenues after taxes show the remarkable increase of 65.5 per cent. The railway department increased operating revenues 13.1 per cent, while increasing the expenses only 1.8 per cent. Net revenues in this department were increased 37.8 per cent over 1928. The bus division likewise showed a substantial increase in operating revenues amounting to 48.9 per cent with increased operating expenses of only 38.9 per cent. The net bus operating revenues are 80.7 per cent higher than in 1928. Since 1925, earnings in the railway division have increased 2.11 cents per car-mile, while operating expenses were decreased 1.37 cents per car-mile, leaving an increased net rate per car-mile of 3.48 cents.



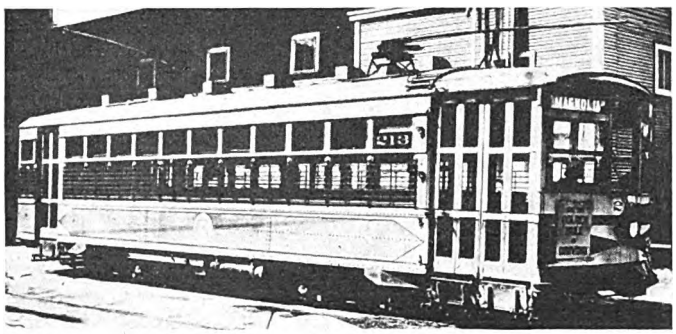
Efficient operation and aggressive merchandising have resulted in greater net revenues for the Eastern Texas Electric Company

Operation of buses began on this property in 1924, and showed a net loss of 8.76 cents per bus-mile. In 1929, this figure had been turned to a net profit of 6 cents per bus-mile. Earnings on invested capital in 1929 amounted to 10.2 per cent. Net income was increased $88,625 in 1929 over 1928, and this increase amounts to 6.8 per cent on the corporate capital stock.

The company's invested capital account increased $467,000 since 1926 and this includes the funds necessary for acquisition and the improvement of the Port Arthur property. The capital for this expansion was secured through temporary borrowings and all but $145,000 has been repaid out of earnings. Net additions to invested capital accounts during the past three years were returned in a period of eighteen months on the basis of 1929 operating revenue. Net additions to invested capital accounts during 1929 were returned by increased operating revenue in a period of 6.4 months. In addition to repaying a substantial proportion of the money borrowed for expansion, the company has paid stock dividends at the average rate of 6 per cent yearly.

Confronting the Eastern Texas Electric Company in 1929 was not the problem of rebuilding a rundown property or of building up good will which had been destroyed, but rather a problem of increasing a patronage that had in the past been gratifyingly satisfactory and of improving public relations that, throughout the long history of the company, had been above average. This problem could only be solved by thorough and efficient merchandising. Modernization of equipment as well as that of tracks and their maintenance played an important part in this program. That the rolling stock was kept in good operating condition is attested by the fact that the railway equipment during 1929 operated 52,400 miles and the buses 3,332 miles to every pull-in.

As a requisite to success in merchandising the service, the operating personnel took a place of equal importance with modern equipment and convenience, locations of lines and adequate schedules. The company's policy is to employ platform men who are not over 28 years of age. They are carefully selected and trained not only in the work which they are to do but as salesmen of the company's service. The men are urged to live in different portions of the city for the possible good to be attained through association in scattered neighborhoods.



Modern equipment is used on city and interurban lines in Beaumont and Port Arthur, Tex.

Round-Table Discussions Held on Many Subjects

TEN luncheon conferences were held at the San Francisco convention of which three were in connection with the work of affiliated bodies. The other seven were on general topics. Much valuable discussion developed at all of them. Brief reports are given below or elsewhere in this issue.

Relief of Street Traffic Congestion

NEED for scientific methods of locating traffic signals and the effects of parking regulations were the principal subjects discussed at the luncheon conference on "Relief from Traffic Congestion." In the absence of G. A. Richardson, E. J. McIlraith, Chicago Surface Lines, led the discussion.

R. T. Dorsey, city traffic manager, Los Angeles, questioned the possibility of setting up a minimum standard code for the location of traffic signals based on the number of vehicles passing a given intersection.

Some divergence of opinion was evident on the subject of manual operation of traffic signals by police officers. Mr. McIlraith held that manual operation is never as satisfactory as properly timed automatic control, while E. L. Byington, chief inspector Market Street Railway, San Francisco, stated that local conditions have sometimes made necessary manual control on Market Street during peak-load periods.

In reply to an inquiry by E. C. Mitchell of the Los Angeles Retail Dry Goods Association, Mr. McIlraith summarized the history of no-parking legislation in Chicago and pointed to the present agitation for parking restriction on the part of merchants on Milwaukee Avenue as concrete evidence that the parking ban in the central business district has proved its merit.

E. F. Thayer, St. Louis Public Service Company, pointed out the real service which local transportation people can render to the downtown merchants of their communities by working to convince them that their own ultimate salvation lies in taking a constructive attitude toward the street traffic and parking problems. He indicated the analogous situation between the former adverse attitude of merchants toward the by-passing of through traffic and the present unwillingness to listen to suggestions that curb parking in front of their stores be eliminated and the streets reserved for traffic movement rather than used for garaging space.

The advantages of staggered office and store hours and the merits of taxicab stands as compared with unlimited cruising were also discussed.

Others taking part in the discussion were R. T. Dorsey, city traffic manager of Los Angeles, Ralph Robinson, manager of the San Francisco Traffic Survey Commission, and James Davis, deputy chief of police of Los Angeles.

Fare Structures

SUMMARIZING the present situation on fare structures, A. S. Richey, Worcester, Mass., who presided at the luncheon on this subject, pointed out that flat fare increases have not proved entirely satisfactory. However, while exact theoretical fare structures could be worked out it would be impossible to put them in practice. There are three difficulties, he said, which prevent exact fare systems working: to determine the exact fare due from each individual passenger; to collect the fare without slowing up the service; and to audit it. When and if such problems can be solved, the proper fare structure will be in sight. In the meantime, many interesting experiments in fare structure are being made.

J. G. Hunter, transportation engineer California Railroad Commission, felt that if a 5-cent base fare is retained it is necessary to go to zones. He has grave doubts as to whether high fares will do any good, at least under conditions existing in California cities.

G. H. Binkley, Market Street Railway, San Francisco, stated that on his property, while the 5-cent fare is not satisfactory as a revenue producer, he questions whether an increased fare would be helpful. A. S. Tilestone, Key System Transit Company, Oakland, stated that his company is now charging 7 cents, excepting that an all-day pass is used on Sundays and holidays. This has proved profitable, he said, and has brought in some additional revenue. Frank Karr, Pacific Electric Railway, Los Angeles, mentioned various changes made in fare rates.

H. S. Dixon, San Diego, said that the fare structure in that city features two city zones, inner and outer. In each there is a 5-cent flat cash fare with tokens good for two zones sold at the rate of four for 30 cents. Some of the suburban routes have as many as ten zones with a fare of 5 cents in each and with reduced rate tickets. There also is a weekly pass on the system sold for $1, which is good in either inner or outer zone, and a school pass restricted to school districts. The pass, he said, has made possible one-man operation, as it is used by one-third of all the passengers.

W. W. Holden, San Antonio, described the service zoning in that city. All street car lines are cut off at a 3-mile radius from the center. There is a second zone 1½ miles wide outside of that and other zones are beyond. In the outer zone, buses are operating which run express through the inner zone. This automatically segregates the passengers into social groups, which he has found helpful. The service is speeded up in the outer zones about one-third. It has made it possible to give improved service without increase in equipment.

R. E. Moody, Milwaukee, discussed the new fares in effect in that city. These include 10 cents cash with reduced ticket fare and pass. The pass, he said, is well liked. In St. Louis there is a modified permit plan. A card good for twelve rides is sold for $1. This is punched by the conductor each time a ride is taken, and after it has been punched

Digitized by Google

twelve times it is accepted on payment of 5 cents a ride.

L. R. Nash, Boston, summarized the discussion. He indicated that with service such as that given in San Antonio it is necessary to have a sufficient demand to give reasonable headways in each zone. The nickel permit, he believes, has advantages over the weekly pass, in that it distinguishes between casual and regular riders.

Employees Relations and Trainmen Conference

AN ACTUAL trainman's conference with thirteen motormen and conductors, under the direction of T. A. Bragg, superintendent of training and employment, Market Street Railway, San Francisco, was held before approximately 60 delegates at the luncheon on employee relations. The trainmen represented employees who had been in street railway service from 8 to 29 years. The total number of years represented by the entire group was 231. Mr. Bragg announced to the group that the subject for their consideration would be, "Interesting the Customer." The men, asked to analyze this subject, took up the various elements in obtaining more rides from the public.

A further question was asked the group about getting back the rides that have apparently been lost due to automobile and other competition. It was unanimously agreed by these representative trainmen that they should go out and solicit new business. Door-to-door canvassing and merchandising methods were discussed.

Following this demonstration, Edward Dana, general manager Boston Elevated Railway, sponsor for the luncheon, expressed his appreciation of the conference held and told of similar methods of employee contact being carried out in Boston.

Transportation Problems of the Small City

IMPROVED and intensive merchandising methods, accompanied by the best possible service that can be rendered, are the greatest needs of the transportation systems in small cities, according to those who gathered for this conference, which was in charge of F. L. Butler, vice-president Georgia Power Company.

In his opening remarks, Chairman Butler emphasized the importance of the small-city problem and the necessity for taking immediate steps to place them on a sound operating and financial basis. "Any community," he stated, "that expects to expand and prosper necessarily requires some form of dependable and economical public transportation."

The report of the committee on small-city operation, not presented at the regular T. & T. sessions, was read at the luncheon conference by Mr. Butler. The report is summarized elsewhere in this issue.

In the discussion which followed, the subjects of bus substitution, transferring from car lines to feeder buses, selling the service, employee sales campaigns, radio, new equipment, one-man operation, public relations, fares and market surveys were covered.

Those who participated included C. B. Short, Roanoke Railway & Electric Company; John H. Pritchard, Central Public Service Corporation; E. W. Florence, Pacific Gas & Electric Company; A. C. Bradley, Pacific Electric Railway; W. N. Clark, Southern Colorado Power Company; W. H. Heun, Chicago & Joliet Electric Railway; Maxwell E. Benson, Nashville Railway & Light Company; R. E. Plimpton, White Company; and A. H. Gossard, Middle West Utilities Company.

Interurban Management and Operation

DISCUSSION at the round-table luncheon on interurban management and operation, sponsored by D. W. Pontius, centered around plans for recovering the transportation business lost by electric roads. Of particular interest was the discussion of the store-door pick-up and delivery system inaugurated by the Pacific Electric Railway in southern California a year ago. Under this plan the railway company contracts with trucking agencies at terminals and important stations along the line to perform the pick-up and delivery service. Mr. Pontius stated that this service has doubled their business without loss of their former traffic.

It was the consensus of opinion of all those who discussed this important subject that store-door delivery offers the most promising solution.

Development of Cars and Equipment

GOOD vehicles are essential to good public relations and there is no more important problem before the electric railway industry today than the development of improved cars. Unanimous agreement on this point was evident from the discussion at the "car development" luncheon under the sponsorship of Dr. Thomas Conway, Jr., president Cincinnati & Lake Erie Railroad. He stressed the need of organizing the mechanical men of the industry to secure the benefit of their ideas and experience in the work of the President's Conference Committee. The electric railway as a business undertaking cannot survive unless it can be put on a profitable basis, he said, and the key to the situation is the electric railway car.

Enthusiastic support of the program of the committee was expressed by C. C. Vargas, Key System Transit Company, Oakland, Cal.; J. M. Yount, Market Street Railway, San Francisco; E. B. Meissner, St. Louis Car Company; George Frey, J. G. Brill Company, and C. E. Morgan, Cincinnati Car Company. Mr. Meissner also emphasized the importance of developing methods of financing new car purchases. Prof. D. D. Ewing, Purdue University, prophesied that much good would result from the concentrated research work now being undertaken. Recent experience with new cars in Chicago was outlined by H. H. Adams. That people can be induced to ride only by making the vehicles attractive was the opinion expressed by G. J. Shave, of the London General Omnibus Company.

In connection with the problem of improving rolling stock, a lively discussion occurred concerning depreciation reserves and their effect in making possible the purchase of new cars. W. G. Rennison, Petaluma & Santa Rosa Railroad, spoke of the difficulty which many railways have in setting up adequate depreciation reserves and doubted that it would be possible to depreciate new cars on the basis of a ten-year life as has been suggested. Richard Sachse, Key System Transit Company, and Dr. Conway expressed the opinion that the railways would be allowed to set up depreciation on the basis of the actual useful life of equipment regardless of whether it was more or less than ten years.

Digitized by Google

Co-ordinating the Taxicab

THAT there is a place and a need for taxicab service which should be furnished by the existing transportation companies provided adequate legislation is enacted was the conclusion reached at a luncheon meeting under the sponsorship of J. B. Stewart, Jr., of the Cincinnati Street Railway.

Electric railway traffic has been seriously affected by the increasing use of taxicabs, particularly in certain cities where the cut-rate taxi business has developed into a situation resembling that created by the jitneys some ten years ago. Mass transportation agencies should be protected against unfair competition of this character, he said.

F. W. Doolittle, of the North American Company, suggested that the railways have been making a mistake in failing to recognize the demand for other classes of service than that rendered by their mass transportation vehicles. O. C. Mills, Key System Transit Company, contended that electric railways cannot go into the taxicab business until more adequate regulation is enacted. The bad effects of low-rate taxicab operation in Columbus, Ohio, were discussed by M. L. Evans, Columbus Railway, Power & Light Company. He said, however, that the general public and the merchants are now beginning to resent the manner in which these cabs are congesting the streets. Conditions in Cincinnati were described by Mr. Stewart.

Development of Buses and Trolley Buses

INTEREST in rail-less transportation centered around a discussion of design, construction, reliability of service, and the riding comfort of the different types of vehicles available at the luncheon meeting on "Development of Buses and Trolley Buses," sponsored by E. A. West, Salt Lake City.

Particular attention was given to the features of trolley bus design and operation, especially the high rate of acceleration and retardation and the effect on tire life, which was said to be negligible.

Trolley bus operation was held to be more economical than that of gas buses as the saving in energy costs, even on a fifteen-minute headway, was sufficient to meet the cost of erecting the overhead wires.

In the discussion of motor buses, trouble from gas fumes was held to be one of the biggest complaints. This difficulty was attributed both to design and to the fault of the fuel refiner.

Small-sized buses—those of 21-passenger capacity—were cited as being of especial value for fast schedules and that speed depended on number of stops necessary to handle the traffic. With twenty seconds as the time for taking on and discharging a passenger, schedule speeds are slowed down in direct proportion to the capacity of the bus operated. Thus if 21-passenger buses can make a schedule in 30 per cent less time the cost per seat-mile will be about the same for both buses of large and small capacity. This higher speed is of real sales value. In San Antonio, it is said, complaints are now being received from automobile drivers that buses travel so fast they cannot be passed.

Comments were also made relative to the high cost of replacement parts for some types of units used on buses, of the necessity for providing greater accessibility of parts for proper maintenance and more simplicity in body construction in order to lower maintenance costs.

Claims Luncheon

MATTERS involving the handling of claims were discussed in detail at this conference, in charge of B. F. Boynton, advisory claim agent of the Northwest Public Service Corporation, and president of the Pacific Claim Agents Association. Most of the discussion concerned the ambulance-chasing evil which is now so prevalent throughout the country. This subject has been before the Claims men in the past in a notable series of presentations, and evidence of real progress toward curbing the evil was furnished. In New York particularly has success attended efforts to curb the "shyster."

A feature of the luncheon was a paper on "The Psychology of Accident Prevention," read by L. H. Rodebaugh, Sacramento Northern.

Among those who participated in the discussion were W. H. Renaud, Jr., New Orleans Public Service, Inc.; J. H. Dennis, Seattle Municipal Railway; L. H. Butterworth, Boston Elevated Railway; Ray Taylor, Municipal Railway of San Francisco; Earl E. Grover, Columbus Railway, Power & Light Company; Paul W. Klabunde, Milwaukee Electric Railway & Light Company, and S. A. Bishop, Pacific Electric Railway.

Brady Awards

Won by

Duluth, Colorado Springs, and Lethbridge Railways

Contest based on accident statistics for 1929 submitted on the association's standard report form. Records of more than 200 companies considered

ANNOUNCEMENT of the winners of the 1929 Anthony N. Brady Awards and the presentation of medals and certificates were made at the convention of the American Electric Railway Association held in San Francisco, June 23-26, 1930. The Class A prize was won by the Duluth Street Railway, Duluth, Minn., with honorable mention going to the Ottawa Electric Railway, Ottawa, Canada. In this class, 54 companies operating 5,000,000 or more car and bus-miles annually, submitted their accident statistic reports, which were analyzed for this contest. In Class B, including companies operating from 1,000,000 to 5,000,000 car and bus-miles annually, the first prize was awarded to the Colorado Springs & Interurban Railway, Colorado Springs, Col., with honorable mention to the Calgary Municipal Railway, Calgary, Alta., Canada. Seventy-nine companies competed for this prize. In Class C, including companies operating less than 1,000,000 car and bus-miles annually, the Lethbridge Municipal Street Railway, Lethbridge, Canada, and the Montana Power Company, Missoula, Mont., won the first award and honorable mention respectively. Sixty-eight companies were represented in this class.

Members of the American Museum of Safety and the American Electric Railway Association formed a joint committee to select the winners of these awards. They were Lewis Gawtry, president of the Bank for Savings, chairman; Colonel A. B. Barber, manager of transportation and communication department, U. S. Chamber of Commerce; James H. McGraw, chairman of the board, McGraw-Hill Publishing Company, Inc., and Charles Gordon, managing director, American Electric Railway Association. The awards are a memorial to the late Anthony N. Brady, and are presented each year for the best records of safety made by electric railways in the United States or Canada.

Contest winners this year were determined on a different basis than those of previous years. Heretofore, the actual accident record of the contestant was considered as only 50 per cent of the total scoring. Other factors making up the remaining 50 per cent included: success in gaining good will through efforts or improved safety conditions; open-mindedness in applying original ideas and new developments, originating with others, as to safer operating methods and equipment; reduced maintenance or greater reliability of service resulting from improvements in safety practice; co-operation between management and employees in safety promotion; outstanding accomplishments in measures to promote sanitation and health. Briefs setting forth these factors of accomplishments and the methods by which they were obtained were required from the contestants.

In order to have more companies represented in the contest, the committee decided to change the basis on which the awards would be made. This year the companies submitting their accident statistics were rated according to the number of injuries and number of fatalities reported for the year 1929, the relative rating being 2 to 1—that is, each fatality counted twice as heavily against the company as an injury. The reports used for the committee's analysis were those submitted by the railways on the forms of the American Electric Railway Association. Companies were also invited to submit briefs during the year's contest, so that in case of a tie the briefs might be referred to for further data.

Analysis of the 200 accident statistics reports, which represent a large portion of the electric railway industry, impressed the committee with the degree to which the practice of safety has been developed by the electric railways of the country. How many lives have been saved by this intensive safety work it is impossible to estimate, but undoubtedly the number is very large.

Some idea of it may be gained from the fact that while the volume of traffic handled by street railway companies was about the same in 1929 as in 1920, the number of electric railway fatalities has been reduced from 2,124 to 1,600. This is the more striking in view of the 187 per cent increase in motor vehicle registrations during that period, with its consequent increase in street and highway congestion and an increase in all

Digitized by Google

street and highway fatalities from 17,055 in 1920 to 33,060 in 1929. The electric railway record is one of the few bright spots in the discouraging story of constantly increasing traffic accidents.

The electric railway figures quoted above cover all electric railway fatalities including pedestrians, occupants of automobiles, employees, passengers and others. When the figures on passenger fatalities are examined—fatalities to the people who trust their safety to the street railways—the record is remarkable. The statistics show that only one passenger out of each 300,000,000 carried is killed. That means that the equivalent of more than two and one-half times the population of the United States is regularly transported on the street cars of the country with the loss of only one life.

For the Class A award, the Duluth Street Railway and the Ottawa Electric Railway ran a very close race. Their properties are similar in that each operates both city and interurban service. The Duluth company operates 111 cars and eleven buses, a total of 122 vehicles, while the Ottawa company operates 115 cars and ten buses, a total of 125 vehicles. In Duluth a total of 5,461,671 miles were operated, of which 4,716,050 were car-miles and 745,621 were bus-miles. As compared to this, Ottawa Electric Railway operated 5,149,246 miles, of which 4,716,490 were car-miles and 432,756 were bus-miles.

The accident record submitted by these two companies and the scoring of points against each, as explained above, is as follows:

	Duluth St. Ry. Duluth, Minn.	Ottawa Electric Ry. Ottawa, Canada
Number of fatalities, 1929		
Railway	2	3
Bus	0	0
Total	2	3
Number of injuries, 1929		
Railway	124	100
Bus	12	13
Total	136	113
Number of fatalities per 1,000,000 miles		
Railway	0.42	0.64
Bus	0.00	0.00
Total	0.37	0.59
Number of injuries per 100,000 miles		
Railway	2.63	2.12
Bus	1.61	3.00
Total	2.49	2.19
Score for fatalities		
Railway	6.72	10.24
Bus	0.00	0.00
Total	5.80	9.38
Score of injuries		
Railway	21.04	16.96
Bus	12.88	24.00
Total	19.93	17.55
Total score	25.73	26.93

	Colorado Springs & Interurban Ry. Co. Colorado Springs, Col.	Calgary Municipal Ry. Calgary Alta., Canada
Number of fatalities		
Railway	0	0
Bus	0	0

Bus	0	..
Total	0	0
Score for injuries		
Railway	2.40	4.16
Bus	0	..
Total	2.16	4.16
Total score	2.16	4.16

Class B contestants, those operating from 1,000,000 to 5,000,000 car and bus-miles annually, were led by the Colorado Springs & Interurban Railway, a company operating city and interurban service, while the Calgary Municipal Railway received honorable mention. The Calgary company operates only city service. A comparison of equipment and miles operated between these two companies is as follows: Colorado Springs company operates twenty cars and three buses, while the Calgary company operates 81 cars and no buses. In Colorado Springs, a total of 1,493,024 vehicle-miles were operated during 1929, of which 1,341,137 were car-miles and 151,887 were bus-miles. The Calgary Municipal Railway oprated 3,070,251 car-miles. The accident records with respect to injuries and fatalities together with the corresponding score for place, are as set forth in detail in the table at the left.

In the third group, or Class C, the Lethbridge Municipal Street Railway operates city service only, while the Montana Power Company operates city and interurban service. In Lethbridge five cars operated 253,064 miles during 1929 while the Montana Power Company operated nine cars over 440,663 miles. Their statistics and ratings are shown in the following table:

	Lethbridge Municipal St. Ry., Lethbridge, Canada	Montana Power Co., Missoula, Mont.
Number of fatalities, 1929	0	0
Number of injuries, 1929	0	1
Number of fatalities per 1,000,000 miles	0	0
Number of injuries per 100,000 miles	0	0.23
Score for fatalities	0	0
Score for injuries	0	1.84
Total score	0	1.84

T. & T. Studies

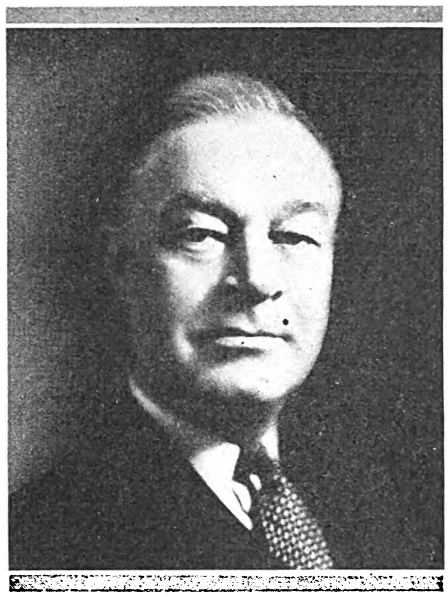
Industry's Fundamental Problems

THREE interesting meetings were held by the American Electric Railway Transportation and Traffic Association at the San Francisco convention. They were attended by a large group which participated actively in the program with discussions, both prepared and extemporaneous. Consideration was given to five committee reports—the transportation employee, movement of the vehicle, operating economics, the passenger and equipment. The sixth report, on small city operation, was read at a luncheon conference.

In the absence of Samuel Riddle of the Louisville Railway, president of the association, Paul E. Wilson of the Cleveland Railway, first vice-president of the association, took charge of the meetings.

The presidential address of Mr. Riddle was presented at the opening of the first meeting by George B. Anderson of the Los Angeles Railway. Mr. Riddle referred to the interesting early history of the T. & T. Association and pointed to the progressive steps it has taken leading up to the present.

"The Transportation and Traffic Association," Mr. Riddle stated, "while the youngest of the affiliated bodies of the A.E.R.A., has made valuable contributions to the industry through the study, research and deliberations of its many committees. The industry's very life depends on the major problem that confronts us today, the diminishing number of riders. We are scarcely maintaining the number of passengers heretofore carried economically and are not receiving the benefits that might be expected to accrue from constantly increasing population. Our plants generally have been estimated to keep pace with the improvements in the arts and sciences, but we do not find a proportionately augmented demand for the service we are capable of rendering. We are challenged today by more private automobiles than ever before. The result of their existence not only is a decrease in the use of mass transportation and an ever-increasing traffic congestion, but our service also is made less attractive to our patrons because we are unable to attain the highest rates of speed possible through the use of modern equipment."



Samuel Riddle
President

Mr. Riddle commented on the subjects selected for committee study during the past year and praised the work of the selected groups.

The report of the transportation employee committee, of which Clinton D. Smith, Cleveland Railway, was chairman, was presented by Jeff L. Alexander, Houston Electric Company. Special attention was given to an analysis of the transportation job with the correlated subsequent supervisory and employee training and a study of proneness to accidents. Each of these subjects was broken down in the report and the individual parts thoroughly analyzed.

Comments upon the report submitted by Prof. Henry H. Norris of the Boston Elevated Railway were read by the chairman. Professor Norris listed six fundamental considerations with respect to the employee. Intrusting the selection to the highest possible type of men, stressing the quality of the contact man, instilling the sales instinct in the men and discouraging snap judgment, analyzing the mental and personal qualifications, and applying psychology. He commented on the advantages in psychological study for the reduction of accidents and indorsed the usefulness of the supervisory conference plan for supplemental training. He also referred to the early work of the association in solving this problem, and pointed out that increasing benefits are accruing from continued research.

A. T. Mercier, Pacific Electric Railway, pointed out that although the present policy of studying past records of employees and then improving them is necessary, more attention should be paid to the proper selection of candidates for positions. He recommended the use of efficiency tests for the classification of employees into groups according to their weaknesses and paying especial attention to each class. "Leadership, discipline, rewards, and remedies," stated Mr. Mercier, "are necessary for developing the most efficient type of personnel."

In support of Mr. Mercier's comments, R. B. Hill, Los Angeles Railway, further emphasized the need for finding competent men. He urged that more money be spent to select men and that the electric railways make their working conditions attractive to the proper type of men. He also pointed out that care should be taken in selecting and training men for departments other than the transportation department. In concluding, he advised that department heads gain the confidence and support of their men through frequent, personal contacting.

An interesting comparison was made by Leslie Vickers, economist of the association, of the sales possibilities for the electric railways and the other public utilities. He pointed out that in the case of the telephone, electric lights and gas, a favorable impression is made upon the public through physical equipment. In contrast to this, he said, the product of the electric railway is dispensed solely by the men on the vehicles. Therefore, their contacts vitally influence the impression of the public. "The transportation employee," Mr. Vickers

Digitized by Google

stated, "needs to know, first, his job; second, the product that he is selling; and third, the people to whom this ride is sold." In analyzing this third point he suggested that employees make a study of patrons, since it is to human beings that the service is being sold.

The second report of the day, movement of the vehicle, of which C. W. Wilson, Pittsburgh Railways, was chairman, was presented by E. J. McIlraith, Chicago Surface Lines. Mr. McIlraith analyzed all of the important sections of the report and commented extensively on those phases which he considered were of greatest interest to the association. Four subjects were covered in the report: the private automobile, the parking problem, signals and traffic control, and equipment.

Mr. McIlraith, in reviewing the parking problem section, restated the general principles that first, parking is a privilege and not a right; second, parking may be tolerated and should be permitted where it does not interfere with the right of the general public to use public ways for travel purposes; third, where parking is permitted it should be regulated in such a manner as to promote safety, a minimum of interference with travel uses, and an equitable distribution of curb space available among operators of vehicles who desire to park; and fourth, where parking interferes with essential travel uses the privilege should be modified, or if necessary, withdrawn.

Some valuable points on making traffic studies were added by Mr. McIlraith in discussing the subject of traffic signals and control. He urged the proper application of signals, following detailed analysis of the requirements, and differentiated between speed and recklessness, in connection with the accident hazard. On the subject of equipment, he read the principal features of existing equipment which are most readily susceptible of improvement, and pointed out that with good equipment the most in the way of speed can be obtained through proper schedules.

A. J. Lundberg, Key System Transit Company, suggested the solving of the traffic problem on the basis of facts. He differed with an opinion in the report that "it is too early in the development of the automobile and facts are too inadequate to draw definite conclusions with respect to the ultimate competitive effects of the private automobile on collective transportation," stating that sufficient knowledge of the automobile's effects in cities of all population classes is available to make analyses of the problem and remedies. He urged that the railways take every possible step to meet the competition of the private vehicle and to rid themselves of a "bankruptcy complex" by keeping the physical plant in the neatest, brightest appearing condition. In concluding, Mr. Lundberg commented on the number of vehicles passing through a given intersection necessary to justify the installation of a traffic signal.

Following the president's address at the opening of the session, the reports of the executive committee and the secretary-treasurer were accepted. In the last report the procedure of the small city committee through the past year was outlined.

Officers for the ensuing term, as selected by the nominating committee, were approved by the association. They are:

President—Paul E. Wilson, vice-president and secretary Cleveland Railway.

First Vice-President—George B. Anderson, director of personnel Los Angeles Railway.

Second Vice-President—R. N. Graham, manager of railways Pennsylvania-Ohio Public Service Corporation.

Third Vice-President—F. L. Butler, vice-president, Georgia Power Company.

Secretary-Treasurer—Guy C. Hecker, general secretary American Electric Railway Association, New York.

Executive Committee—The officers and Adrian Hughes, Jr., superintendent of bus transportation United Railways & Electric Company of Baltimore; D. L. Fennell, general superintendent of transportation Kansas City Public Service Company; C. H. Evenson, superintendent of transportation Chicago Surface Lines; and William W. Holden, manager traction department San Antonio Public Service Company.

Wednesday Session

THE report of the committee on operating economics occupied the entire second session, held on Wednesday. The report, prepared under the chairmanship of Joe R. Ong, Cincinnati Street Railway, was presented by J. B. Stewart, Jr., of the same company. Mr. Stewart selected a number of the most interesting parts and concentrated on these. Five subjects were covered by the committee during the year, those operating practices which have resulted in an increase in gross revenue and those decreasing the cost for operation and maintenance, one-man cars, bus substitution, business-getting and fares. Under the first subdivision a number of practices beneficial to the railway were described.

Comments of the chairman, Joe R. Ong, were submitted by letter and read by Frederick C. J. Dell of the association. Mr. Ong confined his comments to appendices A and B, dealing with proposed methods of cost distribution to routes and classes of bus and electric railway service. He made a number of suggestions for the use of proper units in these proposed methods for the distribution of costs.

Stress was laid by C. L. Van Auken, Electric Traction, on the need of proceeding in this work on an analytical basis. He pointed out that added economies could be secured from further study and that increased revenue could be obtained with intensive research. He also spoke of the need for a scientific fare structure.

At this point, Carl W. Stocks, editor of *Bus Transportation*, was called upon to give observations of his trip by bus from New York to San Francisco. He gave some very interesting details of the 3,400-mile trip and outlined practices with regard to schedules, maintenance and terminal facilities of the long distance bus companies. He spoke favorably of the systematic maintenance and care of these vehicles, reflected by the fact that no serious trouble developed at any time.

"Co-operate with the accounting department in making a cost analysis," was the plea of H. E. Jordan, Los Angeles Railway. He stated that electric railways are handicapped greatly by the lack of satisfactory cost accounting systems and compared the railways as manufacturers of rides, to other large successful manufacturers having comprehensive accounting systems. He further pointed out the possibilities of improving the service and estimating the life of equipment through the securing of accurate and complete data and analyzing these intelligently.

Lester J. Turley, Los Angeles Railway, commended the report on operating economics, particularly the new ideas advanced in it. He told of the use of a manual of operating methods by his railway and told of the results obtained. He also spoke of making a passenger origin survey in Los Angeles and the employees' welfare work of his company.

Comments of A. T. Mercier, Pa-

Digitized by Google

cific Electric Railway, were read by F. E. Geibel of the same company. He stressed the need for comprehensive analyses of practices and costs and stated that the possibilities with existing equipment should be studied first. Concluding, he suggested use of talking movies for advertising.

In answer to inquiries of how the Cleveland Railway adjusted its operating expenses following changes in the fares set-up, Paul E. Wilson explained the type of franchise under which the Cleveland Railway is operating and told of how the accounts are handled. He pointed out that in Cleveland the expenses force the adjustment of fares.

L. R. Nash, Stone & Webster Service Corporation, speaking on the subject of cost analyses, showed the need for a real study of costs so that new classes of business can be developed.

An interesting reflection on the public's reaction to the proposed substitution of trolley buses for gasoline buses was given by E. F. Thayer, St. Louis Public Service Company. He stated that much opposition was voiced to the change in St. Louis and concluded that, from the public's standpoint, the trolley bus occupied a midway position between the street car and gasoline bus.

Thursday Session

At the final meeting of the T. & T. Association, two committee reports were presented, those on the passenger and on equipment. The first was given by William W. Holden, San Antonio Public Service Company. Mr. Holden spoke of the high points of the report, explained the purposes of entering a new phase of study and outlined the procedure to be followed in making market analyses of certain properties. Briefly, the plan is to have Dr. W. J. Reilly, selected for this work, visit the properties for a short period and instruct the personnel in methods of making and analyzing a market survey. Certain parts of this work have been completed, but the plan has not advanced to a point where definite conclusions could be included. The purpose, as explained by Mr. Holden, is to obtain a real knowledge of the desires of the people as a whole for public transportation.

W. H. Lines, Pacific Northwest Public Service Company, spoke of the good results bound to result from market analyses and pointed out the many possibilities of such a survey in learning the attitude of the public, stimulating business and effecting service improvements. He compared the plan to similar efforts of successful manufacturers who produce a good product, develop suitable markets and then inaugurate intensive sales campaigns. Mr. Lines also touched on the franchise situation in Portland and the outlook of transportation in that city.

"Uniform market analyses," stated J. P. Potter, Key System Transit Company, "would be of real benefit to all carriers in the industry." He pointed out that surveys of this kind would show the managements what is lacking in equipment and service and would enable them to get the public and civic authorities interested in transportation. He also told of a house-to-house canvass, made by his company in Alameda, to determine what the people thought of the company and its service.

"Merchandising," stated O. A. Smith, Pacific Electric Railway, "is the basic principle of any business. The railways must recognize this if they are to increase their revenue." Determine what the public wants and then satisfy these desires, was the advice of Mr. Smith. He spoke at some length on the results of fare changes in Glendale and Pasadena, and indicated that by making surveys the results of these and other changes could be forecast.

Some interesting facts which were developed by the market survey made in Roanoke, Va., were related by Walter Jackson, consultant of Mount Vernon, N. Y. He analyzed the relative uses of the pass in the different hours of the day in two districts, one of these being a higher class district. He also spoke of the effect of the telephone and radio, as well as other factors which had an effect on the riding statistics secured in the survey.

The report of the committee on equipment, of which L. C. Datz of the St. Louis Public Service Company was chairman, was presented by F. L. Butler, Georgia Power Company.

In commenting on the report, C. E. Morgan, Cincinnati Car Corporation, stated that along with placing new equipment in service the railways must determine their markets and the needs of the people. He cited the experiences in Brooklyn of interviewing riders relative to new cars and how vital information which influenced future car design was obtained.

F. E. Geibel, Pacific Electric Railway, told of making several changes in car design and the results of these on the riding public. "All elements of car design," he said, "must be considered from the standpoint of rider appeal." He also spoke of the effect of new equipment in developing the interest of employees.

At the official closing of the convention, C. E. Morgan praised the work of President Samuel Riddle throughout the previous year and welcomed the new president, Paul E. Wilson, in behalf of the association.

Transportation Problem Outlined to Electrical Men

SPEAKING at a luncheon meeting of the San Francisco Electrical Development League at the Palace Hotel on Monday, Charles Gordon, managing director A.E.R.A., presented an outline of the local transportation problem and its relationship to general business. He pointed out that it would be physically impossible to provide individual transportation in congested districts for everyone who wishes to ride. In fact, it was the congestion caused by the use of individual vehicles more than 200 years ago in the streets of London that resulted in the inauguration of the first public transportation service. Today a tendency exists to think of the transportation problem in terms of vehicles rather than people. Such an approach to the problem is wrong, he said, as it is people, not vehicles, who do business. He pointed out that one four-track rapid transit line will carry more people than 25 express boulevards, and one double-track street railway line will carry more people than four express boulevards. It is essential that the relative carrying capacities of these different facilities be correctly appraised by the public if an effective solution is to be found for the local transportation problem.

Economics, Methods and New Designs

Studied by Engineers

APPLICATION of engineering practices to all phases of railway activity, with the aim of increasing the number of riders and catering to their comfort and convenience, was the principal subject of papers and discussions at the three general meetings of the Engineering Association in San Francisco. Contrary to the practice which has been adopted at the past several conventions, separate sessions were not held by the divisions of this association. Reports of the various committees were presented at the second meeting. At the third session, held on Thursday morning, the following officers were elected for the coming year:

President—L. D. Bale, superintendent of power Cleveland Railway.

First Vice-President—Charles H. Jones, general manager Chicago, South Shore & South Bend Railroad, Michigan City, Ind.

Second Vice-President—P. V. C. See, superintendent of equipment, department of railways, Northern Ohio Power & Light Company, Akron, Ohio.

Third Vice-President—E. M. T. Ryder, way engineer Third Avenue Railway System, New York.

Secretary-Treasurer—Guy C. Hecker, general secretary American Electric Railway Association, New York.

Executive Committee—The officers and W. W. Wysor, junior past-president, chief engineer United Railways & Electric Company, Baltimore, Md.; Howard H. George, superintendent of way Cleveland Railway; A. T. Clark, superintendent of rolling stock and shops United Railways & Electric Company, Baltimore, Md.; W. E. Bryan, superintendent of power St. Louis Public Service Company; and J. Fleming, purchasing agent Capital Traction Company, Washington, D. C.

President W. W. Wysor, of the Engineering Association, in his address urged the engineers to realize the responsibility which rested on them in all departments of the railway. He said in part: "We were faced during the war with a crisis no other major industry was called upon to bear—100 per cent increased operating expenses with little or no increase in fare. The engineers' answer was greater efficiency accomplished through numerous economies and the use of labor-saving machinery, as well as building better and more lasting structures. Machinery which was not used when labor was cheap was pressed into service with increased efficiency and better work.

W. W. Wysor
President

"With the economic limit of rate of fare already reached in many cases the question arises as to how we are to meet a keenly competitive situation which has now arisen and still keep our properties solvent. We must seek still further economies, more efficient methods and ways and means of increasing the number of riders. We must cater to that class of people to whom the difference between 10 cents and $1 means much; to the man who is becoming tired of the eternal pursuit of a parking space; to the mid-day shopper; to the person who is seeking just a little more in the way of speed, comfort and convenience. We must seek further relief from the burdens of taxation, which are unreasonable and unjust. We must seek for reduction in street congestion, especially unreasonable parking of private automobiles. In the hands of the engineer rests the secret of the solution of many of these problems."

Following the president's address a paper on "Electric Railway Special Trackwork" was presented by B. P. Legaré, engineer of maintenance-of-way and construction Market Street Railway, San Francisco. He reviewed the development of special track construction during the past 25 years and discussed in detail the modern construction of special work employing manganese and chrome nickel. "The problem of crossing design," said the speaker, "should be approached both from the engineering and foundry viewpoint, making full-size samples of numerous designs of crossing intersections and then subjecting them to destruction tests. The engineer must determine the direction of the forces acting upon the structure and then design a theoretical structure capable of withstanding those forces. The foundryman must examine the engineer's design and determine whether the theoretically designed sections can be made solid and without defects of other natures, for unless the metal sections are sound they cannot possess the properties ascribed to them by the engineer."

Regarding the question of what type of special work should be used by a company, Mr. Legaré said that there is no hard and fast rule. All kinds of conditions enter into the subject; the main ones being the amount of traffic, the cost, and in some locations pavement alone decides the type." Following the paper a discussion by members of the association brought out a comparison of the various advantages and disadvantages of manganese and chrome nickel steel structures.

Frank M. Harris, chief of the bureau of specifications and estimates, department of engineering, Pacific Gas & Electric Company, San Francisco, presented an interesting study on "The Relationship of Purchasing and Engineering."

"The Engineer and His Valued Influence in Western Development," was the subject of an address by A. T. DeForest, vice-president United States Steel Products Company, San Francisco. The speaker paid tribute to the engineers of the electric railway industry, as well as to other engineers and their work in developing the resources, transportation and general progress of the West.

A paper on the "London Omnibus and Other Forms of Passenger

Digitized by Google

B. P. Legaré

Transportation" was presented by George J. Shave, operating manager and chief engineer London General Omnibus Company, Ltd., London, England.

Mr. Shave made no attempt to compare conditions in London to those in our American cities when he advocated the general use of the bus rather than the street car. He pointed out how narrow streets, traffic congestion and short turns would be a handicap to successful electric railway operations in London. He stated that the 50-passenger double-deck, four-wheel bus seemed to be the solution of the transportation problem in that city. Mr. Shave told about the research work his company is carrying on with the heavy oil compression ignition type of engine. He stated that he believed an engine of this type will come into general use in the very near future. At present the London General Omnibus Company is operating about 100 buses in which Diesel engines have been installed.

The final paper of the first session, on the subject of "Economies of High-Speed Street Car Motor and Drive," was presented by C. Bethel, manager railway motor engineering department, Westinghouse Electric & Manufacturing Company. This paper was received with a great amount of interest by the delegates and brought forth some interesting discussions and questions. During the discussion, H. H. Adams, superintendent of shops and equipment Chicago Surface Lines, gave a valuable supplement to this paper by informing the meeting of the results so far obtained on his property with high-speed motors and drives. He confirmed Mr. Bethel's contention that the high-speed motor was here to stay and that its further development would be of great value to the industry.

Committe Work Reviewed in Two Sessions

Reports of the various committees of the Engineering Association occupied the greater part of the second and third sessions held on Wednesday afternoon and Thursday morning. For the most part, abstracts of the different reports were read before the sessions and, in a number of cases, were followed by active discussions. Particularly interesting discussions were held on several of the power committee reports and on the report which dealt with rail corrugation. On the latter subject a number of delegates told of their experiences with corrugation under various conditions and of the practice, which is becoming quite general, of grinding new rail immediately after it is laid.

The only paper to be presented at the second session was given by Lester S. Ready, consulting engineer of San Francisco. The subject of his paper was "Engineering Challenges of the West." Mr. Ready did not deal with engineering problems of the street railway, but very completely and interestingly gave the delegates a picture of California and the West in general from an engineering standpoint. He described the number of engineering problems which had been met during the development of California and also of projects which are planned for the near future. He dealt specifically with distribution of water, power transmission, and highway construction.

L. S. Ready

During the third and final session, a paper on the elimination of waste, prepared by A. S. Duncan, assistant director of finished stocks, Westinghouse Electric & Manufacturing Company, was read to the association. An abstract of this paper is published elsewhere in this issue. A second paper presented at this session, "Modern Vehicles and Equipment for Urban Transportation," was prepared by C. A. Burleson, transportation engineering department, General Electric Company, and read by L. Larson, San Francisco representative for the General Electric Company.

The closing acts of this association were to elect the officers for the coming year and to induct them into office.

Engineering Influence in Western Developments

Speaking before the Engineering Association, the author credited the engineer and the electric railways with the foresight that broadened areas of agriculture and industrial operations

By A. T. De FOREST
Vice-President United States Steel Products Company
San Francisco, Cal.

SINCE the days of '49 and the several succeeding years, during which immense wealth was taken from the mines and streams of California, rapid strides have been made in the direction of improved means of transportation and communication, also in the development of agriculture, industries, and transportation by both railroads and

Digitized by Google

steamships. Railroads have been constructed and extended, and extensive highways provided for vehicular traffic to reach what were far distant and inaccessible sections, and there is more to follow. Along these developed lines of transportation, local improvements, communities and new industries have arisen.

In the development of manufacturing industries, the question of power was the important one. No coal of high quality was to be found, and the discovery of oil was yet to come. Therefore, the power in our mountain streams furnished a subject of study. With the long distance existing between the points of possible production of hydro-electric power, and the desired points of utilization of the same, it required able engineers to conceive, and bold promoters to finance, the projects to meet these conditions in the West. The first long-distance high-voltage transmission line in the world was constructed in 1891 in southern California by Prof. C. G. Baldwin. This engineering, constructing and financial genius laid the foundation for our great electric public utilities.

A. T. DeForest

The increase of population brought an urban and interurban transportation requirement, and the growth and breadth in agricultural development produced a like requirement. These needs came to be provided for, in a large measure, by electric railways, made possible by the abundance or cheap electric power. These electric railways have tended to further broaden the areas of agriculture and industrial operations, and build up many communities distant from our metropolitan centers. They brought comforts to the people, and, naturally, increased realty values. Many of them replaced unremunerative service of steam railroads so that they were welcome even to their competitors.

Relations of Purchasing and Engineering

The speaker, before the Engineering Association, pointed out the necessity for engineering advice and responsibility in present-day purchasing

By FRANK M. HARRIS

Chief of Bureau of Specifications and Estimates
Department of Engineering, Pacific Gas & Electric Company
San Francisco, Cal.

BOTH purchasing and engineering have been evolving rapidly during the past two generations. Forty years ago purchasing embraced a knowledge of prices and their seasonal and cyclical trends, where and when to buy, and in what quantities, for maximum economy. During the past twenty years, however, the purchasing agent has been confronted with new factors involving the economies of production and distribution in his markets, coupled with fundamental advances in scientific research and in technical engineering.

The old time purchasing agent with his sound business ability and his trading sense came to talk a new language in which chemistry, mechanical reliability, economies of performance, and technical suitability for a given use are discussed. Steel was no longer just steel; it must satisfy one of the many standards of the national technical societies, in which carbon, phosphorus, and sulphur are specified to one-hundredths of one per cent. Paint was no longer just paint; it must contain certain vehicles and certain proportions of pigments of certain specified ingredients and must pass certain specified tests before and after application. The purchase of all of the common materials of industry was thus complicated by fine technical requirements and standardized specifications, which seriously handicapped the old time purchasing agent buying on price alone.

In parallel with the growth in the complexity of purchasing, an equally distinct transition was apparent in the engineering profession. The engineer of 40 years ago was a specialist in name only. He designed, bought materials, contracted labor and supervised construction, supposedly with equal skill, even when he was not called upon to lend a hand with the financing of the project upon which he was retained. With the entry of specialization into his profession, the engineer was confronted with the necessity for skilled assistance in purchasing, in the person of a specialist who knew markets, materials and vendors, and who could buy wisely.

Frank M. Harris

No feature of purchasing is more important than that of the inspection and testing of materials and equipment. Shall the purchasing agent or the engineer be charged with that? Who shall control the research and development work in the industry concerned? Who shall have the approval of performance bonds, payments on contracts and guarantees? Who shall accept completed work?

Where these technical decisions are being made by engineers attached to the staff of the purchasing agent, the purchasing department is to that extent becoming an engineering department and to precisely that extent is weakening the authority of the engineer, without relieving him, in the slightest degree, of his responsibility.

If this authority - responsibility measuring stick be applied, fairly and fearlessly to co-ordination problems, the division of duties will be such that none can complain and the millennium will have come.

Economies of

High-Speed Motor and Drive

In this address before the Engineering Association, Mr. Bethel shows how high speed affects operation and design

By C. BETHEL

Manager Railway Motor Engineering Department
Westinghouse Electric & Manufacturing Company

ECONOMIES and advantages of high-speed electrical apparatus design are now well established. The operating speeds of turbines, generators, rotaries and heavy traction motors have all been increased in order to obtain reduced weight for the same rating. Why not take advantage of speed in street railway motor design? In the past this could not be done, except to a limited extent, because of the limitations of single reduction gearing. These limitations have been removed. Inherent economies in power, schedule speeds and maintenance have been shown.

Operation over a period has given a clearer picture of the problem of correlating the motor, drive and truck design, and has brought out the necessity of doing so to get the greatest benefit from the new design.

A more consistent and determined effort on the part of both designers and operators has probably been directed toward the reduction of weight than toward any other one feature of the street car. The original single reduction motor, which was rated at 30 hp., weighed, complete with gears and gearcase, 2,750 lb. The latest axle hung motor rates 35 hp. and weighs 1,475 lb. complete with gears and gearcase. This reduction in the motor weight was brought about by developments in both the motor and in high-speed gearing. The high-speed motors now in common use have a rated speed of about 2,000 r.p.m., in the 35 hp. size, and weigh about 560 lb. or 1,060 lb. complete with gears. These weights in the 50 hp. size are 830 and 1,325 lb.

The high-speed motor need not differ fundamentally from the conventional type. It can be built for 600-volt operation along the lines of its very much larger predecessor. However, it is so small that better

C. Bethel

performance will be obtained if a 300-volt design is used. The reason for this is that, with the small commutator, the distance between brushholders becomes so short that the motor is too sensitive to flashing when it operates on 600 volts. With 300 volts on the commutator, however, the volts per inch of periphery are cut in half and the motor becomes much more stable. The voltage to be commutated is also less in the case of the 300-volt motor. There is a further practical gain in the stability of this motor due to its spring suspension, which results in the brushes riding the commutator better. The 300-volt motor is, of course, insulated for 600 volts.

In bringing out the 300-volt motor, the only possible exception to the superiority of 300 volts over 600 volts was the question of the effect on wheel slippage. However, after a service of over one and a half million car-miles with 300-volt motors under all operating conditions of snow, ice, leaves and slippery rails, not one case of wheel slippage due to the use of this voltage has been reported. In other words, the use of 300 volts has been a prominent factor in the development of the high-speed motor.

In order to use this high-speed motor, some form of high-speed gearing with a high gear ratio had to be provided. The problem is to secure a gear ratio up to about 10:1, to eliminate gear noise, to obtain a long gear life, and to obtain a good overall truck design. The worm gear meets the first two requirements of the problem entirely. Ratios even greater than 10:1 may be built quite successfully. The worm gear is inherently the quietest form of gearing, and it never becomes noisy. There is a further advantage inherent in the worm gear in that, with it, it is possible to obtain a large ratio with a minimum of parts.

The principal disadvantage of the worm gear is that it is less efficient than the other types of gears and requires that the motor be placed in the truck with its axis perpendicular to the axle.

The simplest form of gearing is the spur type. While the conventional type of spur gears is somewhat noisy the development of the self-contained gear unit of the double reduction type has virtually eliminated all gear noise. The primary reasons for this are: Bearings on each side of the gears and pinions prevent shaft deflections and assure correct alignment of the gear teeth; roller bearings assure permanently correct gear centers; bearings of large thrust capacity permit the use of gears of large helix angles; running the gears in a bath of clean oil maintains the gears in their original condition for a long period.

With these two tools—the high-speed motor and the gear reduction unit—we have the basis of practically all of the new street car drives. Two fundamental types of drives have been developed so far in this country—parallel and right-angle.

The forerunner of the present type of parallel drive was placed in service in Wheeling, W. Va., in 1925. This was a modification of a standard 35-hp. motor driving a single reduction gear unit through one coupling. At the end of the test, after 80,000 miles of operation, these conclusions were reached: (1) The feasibility of connecting the gear unit and motor through one coupling was established; (2) to take full advantage of the benefits that were established by this drive requires a lightweight high-speed motor. These features were incorporated in 1927 in the high-speed 300-volt motor and WN drive.

Digitized by Google

The first application of the right-angle drive was made in Springfield, Mass., in 1927. This drive incorporated a number of features then untried in street railway service. The more important of these are: worm drive; differential; provisions for transmitting traction to the axle through semi-elliptic springs; high-speed 300-volt motor.

A number of developments have followed these, but the differences have been in detail and in arrangement. The principal features now being incorporated in the various drives are: (1) the high speed motor; (2) both parallel and right-angle types of drives; (3) trucks with inside and outside journals, with the semi-elliptic spring type of side frame and with the rigid type side frame. Except in fairly minor variations in detail, all of the new type high-speed motor drive designs embody some combination of these features.

One of the chief virtues of the high-speed motor is that its size is such that a material reduction in wheel size and floor height can be made. The WN drive is designed to operate on 22-in. wheels, with 1 in. greater clearance than is obtained with standard motors on 26-in. wheels. It was thought at one time that there might be a slight increase in the wheel and track maintenance due to the use of 22-in. wheels, but experience indicates a decrease.

Modern Vehicles and Equipment for Urban Transportation

Features of modern street cars, trolley buses and gas buses were described by Mr. Burleson before the Engineering Association

By C. A. BURLESON
Transportation Engineering Department
General Electric Company

TRANSPORTATION companies nowadays have so many types of vehicles and varieties of equipment to choose from that it is difficult to know which type of vehicle to select and what equipment to use. Many things besides the economics of the question affect the operator's decision.

In Chicago we find 99 heavy duty, 60-passenger, two-man single-end cars weighing 44,000 lb. and equipped with four 50-hp. motors, PCM-18 point control and straight air brakes with quick application and release valves. These cars with seated load have an initial acceleration of 3 m.p.h.p.s. and will reach 20 m.p.h. in 9.5 seconds. They have a free running or balancing speed of approximately 31 m.p.h. on 560 volts.

In Baltimore some very interesting work has been done. A car has been equipped with 26-in. wheel trucks, GE-301 motors, and PCM control arranged for field shunting. The motors have bottom brush holders for easy inspection and adjustment. An automatic self-lapping valve

C. A. Burleson

is used and the regular air brakes are supplemented with track brakes. This experimental car has an unusually fast getaway, being able to make 30 m.p.h in 600 ft. from rest.

The United Traction Company at Albany is operating a modern lightweight, single-end, 44-passenger, front-entrance, center-exit car, equipped with four GE-265, 35-hp. motors. It has foot operated PCM control, foot operated air brakes and air operated magnetic track brakes. Considerable aluminum alloy was used in the body to reduce weight. The complete car weighs 32,000 lb.

With the four-wheel brake becoming general, street car operators must seriously consider the use of the magnetic track brake to increase braking rates, particularly in emergency, so that they not only can keep up with the procession, but also stop with it. Certainly we cannot make maximum use of our higher-powered cars with higher free-running speeds if we do not take full advantage of this extra power for fear we cannot stop as quickly as the next fellow. Any other form of braking is limited by the adhesion between the rail and the wheels. This is not enough to compete with present forms of transportation and should be supplemented especially for emergency. The magnetic track brake adds 25 to 30 per cent additional braking retardation, and this is particularly necessary with a slippery rail.

Trolley buses have been in successful operation for five or six years but it was only recently that the modern trolley bus was put on the map in this country by the Utah Light & Traction Company.

Chicago has recently put 41 trolley buses in operation as feeders to their street car lines. These buses seat 40, weigh about 17,000 lb., are equipped with 40-in. tires and worm ratio of 10.25:1. Two 50-hp. motors, automatic control and four-wheel brakes make a fast, smooth operating vehicle with a balancing speed of about 32 m.p.h. on 560 volts. In Knoxville, four 43-passenger trolley buses with two GE-298 motors and PCM control have recently been put in operation.

The third vehicle to be considered is the gas-propelled bus. Electric drive is now available for 21-passenger vehicles up to double-deck buses seating 67. Larger and more powerful engines are the talk of the day. The Public Service Railway of New Jersey has recently placed in service 170 high powered gas-electric buses which weigh about 18,500 lb., have a 240-in. wheelbase, seat 40 passengers, are equipped with 40-in. tires and a gear ratio of 9.25:1. The engine has a rated horsepower of 150. Direct connected to this engine is a DT-1121 generator which furnishes power to two motors which, in turn, drive the rear axles. On account of the increased size of the engine a new motor known as the GE-1151 was developed. Each of these motors rates 45 hp., continuously.

Elimination of Waste

Waste elimination, effected through efforts of supervision, was the subject of this address before the Engineering Association

By A. S. DUNCAN
Assistant Director of Finished Stocks
Westinghouse Electric & Manufacturing Company

THAT we are a wasteful nation has long been known, but the extent to which the industries are involved should be studied because recent investigations show that over 50 per cent of the responsibility for waste can be placed at the door of management, and less than 25 per cent at the door of labor, while the amount chargeable to outside contacts, such as the buying public, trade relationships, etc., is least of all.

Since by far the greater percentage of the responsibility rests with management, it stands to reason that to overcome the evils which tend toward waste through carelessness it must be approached from the angle of supervision.

One of the greatest profit consumers in any line of business is unproductive labor. By eliminating this, or at least reducing it to the smallest possible amount, it will often be the means of transferring many a business from red to black entries. While it is recognized that overhead, or unproductive labor, even of the least skilled type, is possibly necessary to some extent, yet there are often ways and means whereby this can be placed on the same basis as productive labor and get the maximum amount of efficiency at the minimum cost by using incentive methods.

The elimination of material waste can be carried to the same extreme as elimination of excess labor waste. For example, take the classification of iron and steel scrap on just two grades alone—what is known as the "No. 2 Steel" and the "Heavy Melting Steel." The former has a higher value than the latter, and, by installing a pair of shears in the majority of the locations, this can be turned into a very profitable proposition, securing about 60 per cent increase in price for this scrap.

It is always desirable to have master keys and go through the workmen's desks or lockers where they usually store material used in their line of operations. This, however, should be done in their presence, and any material in excess of a two days' supply needed for the task they are actually working on at that time should be returned to stores and credited.

A. S. Duncan

What quantity production is to the successful manufacturers — quantity purchase is to the utilities. Where material is sold on quantity discounts, a vital mistake is made in trying to measure successful operation by turnover to the detriment of economy in purchasing. In many instances it is economy to purchase in quantities ranging as high as a year's supply at one time, providing the discounts warrant it and the possibilities of obsolescence through disuse are reduced to a minimum, and arrangements may be made for protracted deliveries. At this point, co-ordination among engineering, purchasing and storekeeping is positively imperative.

Successful business follows an iron-clad rule of writing off each year, into the depreciation account, a certain percentage of the original costs of buildings, tools, equipment, etc., naturally reducing overhead profits to a certain extent, but at the same time paying taxes on only the actual worth of the investment. The same rule may be followed just as conscientiously in the handling of your frozen investment, regardless of what it may be. In following any rule on frozen investment for the first time, the totals, naturally, will be extremely high and, as such, one fears criticism for what apparently seems to be an error in judgment in ordering material, but after this has been in vogue two or more years, the results will compensate for the anguish expended. I don't know where it is possible to save more money, particularly where the investment is large, than by moving material that has reached the slow moving, inactive, or obsolescent stage to a quick turnover basis.

Slovenly housekeeping, more than any other single factor, is the cause of waste. A motor car manufacturer, having purchased a steam railroad, has been quoted as saying that he paid a very substantial dividend on the total money invested by cleaning up and salvaging material found on the right-of-way. Be that as it may, there is no question but that all of us, regardless of lines of business, are extremely careless in wasting material.

Try this. Go through your own storerooms. Notice how the material is piled and protected. Then go to the department that uses this same material and see how they handle it and if they properly protect it before and during its use. From there go to your salvaging or scrap department. You will no doubt find material there that, instead of being sent back into stock after the day's work or completion of the job, has gone into the day's waste and is on the road to the incinerator, or being accumulated for selling to the scrap dealer.

Also, if you have different storerooms, form a committee among your men and let them visit storerooms other than their own and give constructive criticism on methods of cleanliness, piling, and taking care of material. By this method, you will find that you will be able to secure some startling results. Regardless of the experience of the supervisors, men employed handling material, if interested, often will see things that those in authority, as a rule, will pass over. The principal thing, however, is to drill into them cleanliness and neatness. Keeping material fresh, neat and clean should be one of the principal determining factors for efficiency.

Great progress has been made, and we can go still further by remembering the principles of waste elimination, and the definition of the word "waste" as thoughtless or idle expenditure without hope of return.

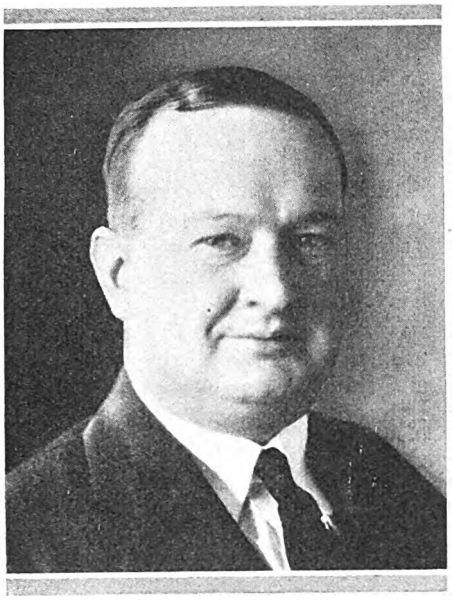
Claims Men Discuss

WITNESS STATEMENTS

and Related Subjects



W. E. Foley
President

IN THE absence of President W. E. Foley, the sessions of the Claims Association were presided over by J. H. Handlon, claim agent of the Market Street Railway, San Francisco, a past-president of the Association.

"The coming together each year at these conventions affords to the claim agent and members of his department a splendid opportunity to exchange ideas with other claims men from various sections of the country," said Mr. Foley, in his address, which was read to the gathering. "It also enables him to keep abreast of the times, which, in my opinion, is one of the essential factors in the claim agent's work. We are all aware of the value of personal acquaintance in the exchange of business courtesies. Time and again in our work there will arise a situation demanding investigation of witnesses or the settlement of claims in distant cities. It is gratifying to know, when such an occasion arises, that a telephone call or a telegram to a fellow member will bring the desired result." Mr. Foley also made a plea for a wider support from the membership of the work in which the Claims Association is engaged.

The report of the executive committee was read by A. E. Nicoletti, assistant claim agent Key System Transit Company, Oakland, Cal., following which the report of the nominating committee was read. The entire ticket was elected, as follows:

President—C. E. Redfern, United Electric Railways, Providence, R. I.

First Vice-President—J. W. Giltner, Northern Ohio Power & Light Company, Akron, Ohio.

Second Vice-President—L. H. Butterworth, Boston Elevated Railway, Boston, Mass.

Third Vice-President—E. S. Nelson, Pacific Northwest Public Service Company, Portland, Ore.

Secretary-Treasurer—Guy C. Hecker, American Electric Railway Association, New York City.

Executive Committee—Officers and Bert C. Wood, S. A. Bishop, E. J. Paige, and G. T. Hellmuth.

Following the official business of the session, the meeting was turned over to B. F. Boynton, president of the Pacific Claim Agents Association, and a joint meeting was held with that body.

Papers were read on "Bus Accidents—Their Causes and Prevention," by S. A. Bishop, general claim agent Pacific Electric Railway, Los Angeles, and W. R. Sherman, general claim agent, Spokane, Portland & Seattle Railway, Portland, Ore. "With my property, 60 per cent of all mishaps are so-called traffic accidents," said Mr. Bishop. "They are responsible for the major part of the work of the investigation personnel, although their costs are only 26 per cent of the total claim costs. They cannot be prevented wholesale unless perhaps by more thorough training of employees and the stricter application of the rules. The best way I know to get definite results is to investigate each accident, go over the facts with the employee involved, point out to him his responsibility, administer commensurate discipline, demand improvement, and follow up with removal from service if the employee is unresponsive or imcompetent."

In the discussion that followed, P. W. Klabunde, of Milwaukee, described the training road which has been built by his property for the instruction of drivers. W. H. Moore, San Diego, spoke briefly of experiences in that city. Mr. Bishop expressed himself in favor of insuring high-speed buses against accidents and carrying the risk on slow-speed city buses. A. E. Nicoletti, assistant claim agent Key System Transit, Oakland, Cal., stated that his company is working to establish the negligence of automobile drivers in many of the accidents which occur. This relieves the company of responsibility. In some instances it has been found possible to bring suit against the automobile driver as the third party where he was at fault in causing an accident in which a patron of the company or an outside person was injured.

Methods of impressing employees with the importance of obtaining all available witnesses and gathering material facts at the time of the accident was the subject of a paper by Mr. Nicoletti.

He stressed the necessity of securing as many competent witnesses as could be obtained, and particularly of getting the names of persons who, although they might not have been eyewitnesses of accidents, were present.

Another paper on the same subject was presented by J. E. McClain, claim agent Austin Street Railway, Austin, Tex. His paper is given in abstract elsewhere in this issue. In the discussion, Mr. Klabunde stressed the necessity of getting facts as soon as possible after the accident occurs.

People passing by on the street are often better witnesses than passengers, since they may have been able to see the entire occurrence, while those on the vehicle might have had a limited view. People who state to the operator that their testimony would be no good as it would be against the company often prove the most valuable witnesses, he said, and should not be neglected. Distances of the various elements involved are impor-

Digitized by Google

tant. They should be obtained at the time of the accident, as marks on the pavement are obliterated soon afterward, particularly if the traffic is heavy. E. E. Grover, Columbus, Ohio, is opposed to the method described for obtaining witnesses. He feels that if the operators are told they must turn in a large number of names, they may not be particular about whom the people are. Mr. Bishop, on the other hand, does not believe in allowing the trainmen to use any discretion, but advises getting as many names as possible and sending out questionnaires to them. This view was held by a number of other speakers.

"The Value of Motion Pictures in Claims Work" was the subject of a paper by C. M. McRoberts, Los Angeles. Mr. McRoberts demonstrated the effectiveness of motion pictures in establishing facts regarding accidents by showing a number of films which he had taken.

Wednesday Session

The second session of the Claims Association, held on Wednesday afternoon, opened with a report of the committee on uniform negligence law which pointed out that in the opinion of those who drafted a sample bill for the consideration of state legislatures the act would prove constitutional if put before the courts and, if passed, would do away with much unpleasant litigation.

In a paper dealing with the subject of whether the company surgeon should call on the injured immediately after the accident or wait until the liability is determined, M. C. Chapman, Jr., concluded that no hard and fast rule could be adopted. Discussion brought out a majority opinion that where the company is obviously liable, the staff surgeon can prove a valuable emissary of the claims department by calling on the injured as soon as possible. Also the value of taking X-ray photographs at the time was stressed. Such records often prove invaluable at some later date.

The subject of blind accidents and how to handle them was covered in papers by G. T. Hellmuth and J. W. Giltner, abstracted elsewhere.

Two papers dealing with legislation affecting guests of motorists who are injured in accidents were followed by lengthy discussion. There is a strong tendency in most states to absolve the driver of a car from liability when carrying gratuitous passengers. Several states now have laws absolving the operator of a motor vehicle of claims in case of accident except in cases of gross or willful negligence. Oregon is the only state to have passed a law absolving the driver of *all* risk but this act has been declared unconstitutional. It was the opinion of the authors of the papers, as well as several who participated in the discussion, that state legislative bodies are in a receptive frame of mind to pass laws which will to some extent define negligence in such cases. Also the belief was expressed that the time is near at hand when jurors will not be permitted to measure negligence by a flexible yardstick but will have this vital point defined by a commission.

Painstaking Investigation Reduces Fraudulent Claims

Eternal vigilance is the price of protection in dealing with blind or fraudulent claims, according to a statement made before the Claims Association

By G. T. HELLMUTH

Claims Attorney Chicago, North Shore & Milwaukee Railroad, Chicago, Ill.

G. T. Hellmuth

BLIND accidents include accidents that really occur and those that are fraudulent. But in either case intensive work by the claim department is imperatively necessary, and especially so in the fraudulent type of claim.

There lies at the root of this evil of blind accidents a ready cure afforded by training all employees to report any and every accident, no matter how trivial it may appear and no matter how disconnected the company may seem to be from the actual occurrence. It is unfair to the company for any employee to allow an accident to be unreported.

As to the handling of fraudulent claims which so often are based upon "blind" accidents, my company has made it a policy for the past eighteen months to prosecute dishonest claimants wherever we could establish such dishonesty, and we have been successful in jailing some ten or twelve of them in the past year and a half.

In Chicago an index bureau is maintained by the insurance companies and supported by most of the carriers. All members report to the bureau the claimant's name and address, and full records are kept, not only alphabetically by name, but also numerically by street number. The bureau does not rely solely on the reports of its members, but indexes as well personal injury plaintiffs and all law suits commenced in Cook County. Through the help of the index bureau, it has been possible time and again to catch a claimant who is in the habit of making frequent fraudulent claims.

I am a firm believer in the policy of painstaking, thorough and complete preparation of any litigated matter, and in my judgment we can hardly go too far in going into every angle and detail. I feel, also, that haste is liable to make waste, if we are too precipitate in paying a "blind" claim. If it is not yet in the shape of a law suit, I think it ought not to be paid until we have turned the strong searchlight of investigation upon it, and if it is sued upon, we should leave no stone unturned in investigating the facts from every possible angle.

Securing the Facts Is the Basis of Accident Investigation

By J. E. McCLAIN
Claim Agent, Austin Street Railway
Austin, Tex.

That unfavorable evidence can be as valuable as that which directly favors the company was the substance of an address delivered before the Claims Association

I AM a firm believer in the great importance of the education and proper instruction of our employees. No operator or other employee of a corporation who has not been instructed in, and taught the fundamental principles of his organization, can render the same efficient service as one who has had the proper instruction and training. The first and most important of these principles which should be conveyed to persons entering the service of a corporation is the principle of elemental facts.

They should be taught that in all cases their first duty to their employer is to gather and present through the proper channels all known facts concerning each particular case, and should supplement this by any other information pertinent to the issue. These facts should be obtained as soon as possible after an accident, and should include evidence unfavorable, as well as that favorable to the company. Failure on the part of the trainman to secure the name of one witness, even, may result in the claim agent of his company making a wrong decision in the case, thereby causing the company the loss of a large sum of money.

Trainmen should be given special instructions in the gathering of evidence at the scene of an accident. Details must be secured at the scene of the accident and immediately after it occurs. A few minutes of delay and at the most, a few hours under ordinary traffic conditions, will tend to erase all traces of the accident on the pavement.

In getting these instructions over to the personnel of an organization in an impressive manner, I know of no better way than for the claim agent to appear before them in person; particularly is this true when there are only a few men to contact. When you get a trainman, who has fallen short in handling his accidents, face to face, and go over the case with him in a friendly and co-operative manner, I feel sure that a great deal more good would result than from any other method which might be used.

When all has been said and done concerning the best methods of impressing employees with the importance of obtaining all available witnesses and gathering material facts at the time an accident happens, the whole thing resolves itself into the matter of education. Give the trainman the proper instruction in the matter of obtaining and presenting all facts pertaining to each and every accident, and we have taken a long stride toward reducing the amount of claims paid because of lack of facts to substantiate our rejection of them.

Blind Accidents and How to Handle Them

By J. W. GILTNER
Chief Claim Agent, Northern Ohio Power & Light Company
Akron, Ohio

Methods of investigating and dealing with the unreported accident are set forth in detail in paper read before the Claims Association

BLIND accidents — sometimes called "no-report accidents"— are those about which we receive our first information from an outside source. It may be advice from an attorney who represents the claimant; it may be a telephone call from the claimant or some neighbor, friend or relative acting for him; it may be a call from the doctor in attendance, the favor and co-operation of whose fraternity we have always tried to merit; occasionally the information is relayed through one of the operators of a following car or bus, and now and then a claimant comes to our office and presents the matter in person.

In all cases except those reported by attorneys, it seems to me the course of our procedure is obvious. The injured person must be interviewed at once, in his home if possible, where, surrounded by his household goods, his family and neighbors assembled, a more accurate estimate of his honesty and reliability is possible.

In this first interview the investigator will go into the claimant's past history and watch intently for previous accidents, injuries, sicknesses and for doctors and lawyers used by himself and intimates. He will learn his places of residence, his employers, his acquaintanceship with attorneys, his experience in law suits, his church and lodge affiliations, the names of insurance companies with which he has carried accident insurance coverage, and will be on the lookout for evidence of a connection between this claimant and other claimants in shady cases handled previously.

Coming closer to the case in point, the investigator has the claimant detail his movements and associates for several hours preceding the accident. Thus a fund of information is secured—much of it possibly is of no value—but no one can tell what can safely be ignored. In it is found all available material for the investigation. In a second interview the correctness of the data given can be checked in the manner referred to previously.

In the case of a blind accident reported by an attorney, it is our practice to recognize and respect all the rights of an attorney to bring his client and supporting witnesses to our office for an interview. In such cases no further discussion is necessary, for the course pursued is identical with that outlined above.

Accountants Give Attention to

Budgetary Control

E. H. Reed
President

THAT the era of consolidations and mergers which are constantly taking place in the utility field has created new opportunities as well as new problems for the accountant was emphasized by E. H. Reed in his opening address before the accountants' association. The new obligations imposed upon the profession, according to Mr. Reed, call for a full perspective of the science of accounts to enable one to visualize the enormous transactions which are taking place in the present-day business world.

Perhaps the most important feature of the past year's work of the accountant's group has been the work of the committee on budget control, which has devoted itself to the preparation of a model budget in detail which, when completed, should be of great value to operating managements.

Mr. Reed paid tribute to the committees having in charge the subjects of standard classification of accounts, bus accounting, stores accounting, fare classification, and freight accounting, reports on all of which were submitted at the meeting.

"The Capital Structure of Public Utilities" was the subject of a paper presented by John F. Forbes, resident partner Haskins & Sells, San Francisco. An abstract of his paper appears elsewhere in this issue.

Reports were received from the committee on standard classification of accounts and from the sub-committee on bus accounting. These reports are abstracted elsewhere.

Among those taking part in the discussion were C. C. Vargas, Key System Transit Company, Oakland; P. S. Young, Public Service Co-ordinated Transport, Newark, N. J.; W. H. Scott, Municipal Railway of San Francisco, and A. G. Neal Washington Railway & Electric Company.

How the auditor can most effectively aid his company by becoming an analyst rather than a mere recorder of figures was brought out in a paper presented by Leslie Vickers, economist, A.E.R.A., at the second session of the Accountants' Association. An abstract of this paper appears elsewhere in this issue. Following the presentation of his paper, Mr. Vickers gave an interesting explanation of the attitude and plans of the Interstate Commerce Commission in the matter of cost accounting. It was brought out by Mr. Vickers and also by John F. Moran, Boston Elevated Railway, that the subject of obsolescence has a very important bearing on depreciation accounting. In the absence of the chairman, the report of the committee on budgetary control was presented by C. E. Yost, Delaware Electric Power Company. This report is abstracted elsewhere.

Resolutions were presented on the death of three members of the association, W. G. Ross, F. R. Henry and F. E. Webster.

The report of the committee on nominations was then presented. Officers named for the coming year were:

President—C. E. Yost, treasurer and assistant secretary, Delaware Electric Power Company, Wilmington, Del.

First Vice-President—J. E. Heberle, assistant to president Capital Traction Company, Washington, D. C.

Second Vice-President—E. A. Tuson, general auditor Public Service Co-ordinated Transport, Newark, N. J.

Third Vice-President—C. R. Mahan, comptroller Chicago, North Shore & Milwaukee Railroad, Chicago, Ill.

Members of the Executive Committee—L. T. Hixson, secretary and treasurer, Indianapolis Street Railway Company, Indianapolis, Ind.; R. A. Weston, special accountant the Connecticut Company, New Haven, Conn.; R. L. Crowe, vice-president Los Angeles Railway, Los Angeles, Cal., and J. D. Evans, general auditor St. Louis Public Service Company, St. Louis, Mo.

These officers were unanimously elected and Mr. Yost was installed in the chair. A resolution was passed thanking the retiring president, E. H. Reed, for his services during the past year, and the badge of past-president was presented by O. H. Bernd.

Accountants' Luncheon

DISCUSSIONS of capital charges formed the principal topic at the Accountant's luncheon, which was presided over by President E. H. Reed. Those present took up in considerable detail the subject of cost analysis in connection with construction of track. The procedure necessary in taking up the old track and putting down new track in its place was gone over. In the discussions, methods of segregating charges to capital and to operating expenses were considered.

Fare box collection was another topic discussed. It was told that on one property experts showed methods by which the fare box could be rifled. Due to the analysis made, the manufacturer was able to revamp his design and produce a new fare box which would be theft-proof.

Another subject discussed was checking of material and supplies in connection with orders. The case was cited of an order for major repairs to a group of cars. Material was purchased when, had a check been made with the storekeeper, it would have been possible to use the supply of material already on hand and which has been standing idle for some time.

Those taking part in the discussion were E. H. Yost, Delaware Electric Power Company, Wilmington; E. C. Jolley, San Antonio Public Service Company; W. H. Scott, Municipal Railway of San Francisco; J. W. Glendenning, Commonwealth & Southern Corporation, New York; and others.

The Auditor as an ANALYST

Opportunities to do work of great importance and value are outlined in this address before the accountants association

By **LESLIE VICKERS**
Economist
American Electric Railway Association

THE greatest need of our industry today is analysis. You may talk about our need for new cars, for rehabilitated tracks, for new fare structures, for relief from paving and taxation burdens, for traffic regulation and increased public understanding of our business. All of these are necessary and worthy of the stress that is being laid on them, but to discuss them intelligently as applied to any individual property, we need first, the kind of financial analysis that should be made within the auditor's office. It does not necessarily follow that he is the individual who should do it. But he and his associates in the accounting department are the main cog wheels in the machine that can accomplish it. As a matter of fact, there is no one on an electric railway property who can afford not to be an analyst and it is partly because so many of us have accepted things as they are that our industry is in the condition in which we find it today. With certain exceptions, our properties have not done what they should in analyzing service—in finding out what part of it is adequate, what part is inadequate and what part is unnecessary and wasteful; they have not analyzed their patronage to determine whether or not the fares they charge fit the kind of traffic for which they are intended; they have not analyzed the equipment to see if it should be retained or replaced, or whether some alternate form of service should be substituted; and they have not analyzed their operating costs by lines, by routes, by times and by seasons, their shop and track costs by units, or their operating revenues by classes of service or with relation to the new and old investments which they represent. Of course, there are some properties that are doing all of these things and they have approached reasonably close to a thoroughgoing cost accounting basis. Their auditors and accountants are able to tell with a fair degree of accuracy at any moment what the various classes of service are costing, and more than this, they are displaying, in a timely way, the red signals of danger which the operating executive may pass only at his peril. The auditor, by his careful analysis, may not have the final word, but he speaks so authoritatively that he cannot be ignored by those who do have it.

Leslie Vickers

But as an industry we stand in marked contrast with modern manufacturing industry, and indeed with some of the other public utilities as well, in lagging far behind in the matter of cost accounting. Manufacturers must know their individual costs. The time has passed when goods will sell themselves except in certain highly specialized or monopolistic lines—and money is so plentiful, and so eager to find a profitable investment that it soon rushes in to provide competition for the manufacturer who is so careless about his costs and knows so little about his unit margin of profits that he sets his selling price at an attractive point for the establishment of the very competition that will ruin him. A roll call of the industries that have established cost accounting systems and have followed them up to the degree approved by the Taylor Society is a surprising one. It includes the highly seasonal industry of the manufacturer of Christmas cards or the retail distribution of a highly perishable commodity such as milk; it includes ships and heavy machinery builders and confectioners; automobile builders and manufacturers of fly paper; steam locomotive builders and the producers of Eskimo pie. Indeed there seems to be no limit to the application of cost accounting principles, nor yet to the degree of refinement to which they may be carried.

Since I am not an accountant nor an auditor, it is fitting for me to state that I see no great difficulty in the application of very far-reaching cost accounting principles to our industry, and furthermore, I am aware that some up-to-date companies have done much in this direction. But as an industry we must do much more. We must remember that we have a service to sell and not merely to provide. Herein lies one of our weaknesses. Many of us have acted as if our commodity would sell itself, once it were provided. We began our life as a monopoly and some of us have failed to realize that we have developed into a highly competitive business in which we have to provide the kind of transportation that people want, at the time they want it, and at a price they will pay. The old solid iron-tired horse coach could not compete with the horse car on rails; the horse car on rails gave way under competition and development to the cable and then to the electric car, and that vehicle maintained its predominant position for many years until the light passenger automobile came in and demanded smooth surfaced roads, and smooth surfaced roads in turn helped to develop the pneumatic tire. The pneumatic-tired private automobile, operating over roads almost as smooth as our own steel rails, is our great competitor for service today, and we not only have to *furnish* service but we must *sell* service to meet the competition which it creates.

This is neither the time nor the place to insist on the essential nature of common transportation service.

Digitized by Google

Indeed, it is scarcely necessary to assert it at any time or in any place, for it is self-evident and readily apparent to the resident of any city.

But it is both the time and the place to assert the existence of such competition in service, comfort, convenience and price as to force us to the same careful scrutiny of services and analysis of costs as faces the manufacturer of any other competitive article. All of this involves analysis of the most patient kind.

We must all be analysts from the general manager down to the man at the bench; from the superintendent of traffic and transportation to the man on the rear platform; from the auditor to the clerks in the receiving department. But the degree of responsibility varies with the rank of the individual, and this is great in the case of the auditor because of his high standing and his comparative isolation from the routine problems of providing service. It is great because the figures in all the accounts pass before him; because it is his function to make comparisons, and because it is his final authority to pass judgment on the validity of charges and entries.

With such a responsibility and such an opportunity, how can an auditor be content to act merely as a figurer? How can he resist the role of analyst? To remain a figurer is like working in a dingy unlighted office with the grey and uninteresting procession of figures, more figures and more figures passing before his blurred vision, when the opportunity is before him to turn on the light of analysis and scrutiny, breathe life into the columns that face him and see before him an interesting landscape replete with beautiful scenes, living, breathing human beings to be served, and challenging problems to be solved. The analyst's attitude toward his job will lift it out of routine, work-a-day toil into the realm in which students work because they enjoy the search for truth; into the realm of causes rather than the realm of facts; into the realm of things dynamic and full of life and out of the realm of things static and lifeless.

Capital Structures of Public Utilities

In an address before the Accountants' Association the author outlines the various entities of which utilities are composed

By **JOHN F. FORBES**
Resident Partner, Haskins & Sells
San Francisco, Cal.

PRIMARILY the financial structure of any corporation is disclosed by its balance sheet, but there are a great many reasons why the balance sheet of a public utility while apparently similar in form and content to that of every other form of enterprise, must be considered from an entirely different point of view.

In the case of a manufacturing or trading company, for instance, the current financial position is of outstanding significance. In considering the propriety of credit extension to such enterprises, bankers emphasize the relationship between current assets and liabilities since the former normally represent the source from which repayment of loans arises. Logically, the greater the excess of current assets over current liabilities in a given instance, other things being equal, the stronger is the credit position of the borrower. If, as in the past, bankers have usually considered a current ratio of 2:1 satisfactory, a ratio of 6:1 would be proportionately more favorable.

The same method of reasoning however does not apply in the case of the public utility. Indeed the reverse might possibly be true, and for the following reasons: The current assets of any corporation consist essentially of cash, accounts receivable, and inventories, and the current liabilities consist usually of those debts which have to be paid within a twelve-months' period. In an industrial, and in many other forms of enterprise, the cash may be used immediately in the liquidation of the payables. In the normal course of business operations, the conversion of the inventories into receivables and the latter into cash provides the means of liquidating the liabilities. Ordinarily the greater these assets are in relation to the liabilities, the greater is the financial stability of the enterprise.

But in a public utility the amount of cash which may be economically carried is dependent altogether upon the financial plans of the company, and if the accounts receivable exceed the earnings of, let us say, two months, this is probably a sign that the collection department of the concern is not functioning properly or that the company is selling power or transportation, or whatever service it does purvey, in violation of the ordinary rules of business.

The inventories too are not to be converted into cash except in those few instances where appliance sales departments have been introduced into the utility. The inventories usually comprise almost entirely materials and supplies which are to be consumed in the rendering of services to consumers. And the carrying of a large inventory on the part of a public utility may be a sign of great weakness rather than one of strength, for the reason that if the material is not to be used within a reasonable period it represents so much dead investment for the cost of which the company is paying heavily in bond interest or otherwise. So, if a banker is considering the credit possibilities of a public utility, instead of considering the ratios of current assets to current liabilities, he should investigate the daily or weekly or monthly income since that is the source to which he must look for payment.

The banker ordinarily gives little consideration to the fixed assets of the industrials as security for a loan for a variety of reasons. A mill dedicated to the manufacture of cotton stockings might have little value in a silk-stocking era, and the vicissitudes of trade generally serve to render precarious risks based upon such permanent assets. And, too, so-called "capital loans" are likely to become frozen. But the permanent assets of a public utility form an infinitely better security. Even these assets may be seriously affected in their present value, as is illustrated in the effect which the automobile has had upon street car lines, but in the case of the utilities the transition of fixed assets from good to bad is slow.

American Association Committees Active During Year

ON ACCOUNT of the shortness of the Association year, due to the convention being held in June instead of October, it was not possible for the committees to complete their assignments to the extent that is done ordinarily. Many of them are engaged on projects that require a greater time than was available, and were able only to report progress. Four of the committees, those on national relations, street traffic economics, employee relations and publicity, prepared printed reports which were distributed prior to the meeting. Their reports are abstracted below. Other committees made oral reports which are mentioned in the proceedings of the sessions.

NATIONAL RELATIONS

REORGANIZATION of the Washington office was described, and the advantages accruing discussed in some detail.

The necessity for clarification of the Interstate Commerce Act with reference to electric railways was pointed out. The principal development during the year was the Supreme Court decision on the Piedmont & Northern case. This has merely thrown the case back into the lower courts without a decision as to its merits. Since the case involves the entire matter of jurisdiction of the Interstate Commerce Commission, including issue of securities, it is of vital importance to find a solution of the problem presented by it.

The bill to control motor buses in interstate commerce is not yet adopted, and certain modifications are necessary to make it desirable after its amendment by the Senate. Certain other legislation proposed is reported on by the committee.

STREET TRAFFIC ECONOMICS

FOUR principal subjects were studied by the Committee on Street Traffic Economics: (1) Possibilities of signal design; (2) parking in neighborhood business centers; (3) use of the public streets, and (4) taxicab operation. The need for proper engineering treatment of traffic problems is growing more acute, states the committee, and railway managements must take the leadership in directing the development of proper traffic control. Public officials and business men will not develop so great an interest in producing freedom of movement on the streets as the alert management of the transportation system. Competent engineering analysis should be undertaken and careful development by concerted planning with the business groups and public officials should be carried out.

On the subject of traffic control and signaling, the increasing accidents in cities are held to be mute evidence of the ineffectiveness of signals and traffic control as now operated. Transit speeds and riding habit have steadily declined in most cities until the industry is now faced with the problem of street speeds of 4 to 6 m.p.h. or even less through business arteries, and even 6 to 8 m.p.h. on long stretches of trunk arteries. Private transport is equally handicapped.

While the relative numbers of riders and pedestrians vary widely in different parts of a city, rarely are different selective methods adopted to meet these situations. Excessive delays have added to freight delivery costs as well as those of city passenger transport.

The committee believes it is quite clear that the total riding habit or demand for transport is increasing steadily with population growth, as indicated by the necessity riding. Far more intensive study of their problems should be given by both city administrations and operating companies.

Specifically, it is necessary to study the street system and main thoroughfare plan with the object of securing the most appropriate classification for various uses, easing bottlenecks, providing by-passes and releasing full traffic capacity of main arteries pending the development of new ones. Complicated intersections should be given individual study. Signal systems already installed, if not of high efficiency, should be replanned to develop full traffic capacity of thoroughfares under control.

The net effectiveness of present traffic enforcement facilities demands study. This has entirely escaped attention, the committee feels. Transit routing and methods should be examined to discover the best means of expediting progressive movements, promoting short-haul riding facilities, simplifying terminal district layouts and releasing the congested districts from unnecessary turning obstructions.

Study should be given to the joint effect of city and state regulations on transport operations; first, physical regulation over city streets and traffic; and second, economic regulation of the state commissions.

It would appear essential that transport companies participate far more actively in this survey and planning work than they have done in the past, for their own good and protection. Co-operative planning should bring quick and positive results.

Considerable space in the report is devoted to a survey of recent experience and effects of city traffic signaling. While the trend is definitely toward the full flexible progressive system, progress is considered slow and piecemeal, with all too little evidence of signaling conceived as a system on a broad master plan. Examples of city systems are cited, and it is held that only two or three of them approached this ideal. The synchronized system, generally inflexible and with too long cycles, reduces street capacity and speeds to almost half pre-signal values. There also is an increase reported in peak power loads.

Some important points in design are taken up in considerable detail. The necessary information to be secured and methods of analyzing it are discussed. Studies of turning movements and of full street filling are deemed desirable. The cycle length and split-timing allotted must be sufficient to pass the traffic.

Advantages of the skip signal progressive system, with only the main crossings of a traffic artery

Digitized by Google

signaled, 1,000 to 2,000 ft. apart, are not believed to be fully understood. With through-street stop signs on the cross streets at intermediate locations there is reasonable freedom of movement. Along with skip stops trunk transit lines show possibilities of increases of speed of 20 to 25 per cent.

Pedestrians will not wait for long cycles in crossing streets, judging from observations of 60,000 instances. More than two-thirds disobeyed the red signal on a 125-second wait and only one-fourth on a 55-second wait. The short cycle gives both high efficiency and pedestrian protection.

Several pages of the report are devoted to a discussion of results of signal surveys in several cities. The synchronous type of signals gave very poor results, slowing down speeds greatly both in rush and non-rush hours. Street car speeds were reduced 25 to 40 per cent. The effect on the crews has been to discourage them.

Parking also was studied in detail. Elimination of parking would not affect business adversely and would facilitate all vehicle movement. Public transportation should be such as to encourage the use of public carriers.

Taxicabs are considered necessary without question, but the committee did not feel ready to make definite recommendations regarding them. Taxicab stands were discussed, and the results in Chicago, Philadelphia and Brooklyn were cited. It was found that the taxicab traffic constitutes from 3 to 8 per cent of all traffic in the congested area and cannot, therefore, be an important factor in causing traffic congestion.

EMPLOYEE RELATIONS

THIS year the committee on employee relations paid particular attention to the personnel side of the industry. It believes that the conference method of training is the most promising avenue of improved public relations and employee inspiration, and the conclusion was reached that the most important business of the committee is to convince the industry that this work must be done. The present committee and its predecessors have tried to prove that education and training of employees are necessary to secure the best results, and to suggest ways in which the education and training can be given.

For several years it has been urged that the principal value of work of this class lies in two fields: the foreman conference for all supervisory officials, and the employee conference on customer contacts or service betterment. At conventions, demonstration foreman conferences have been given and training courses for leaders of such conferences have been conducted. This year the location of the convention and the short time have made it difficult to continue along the same lines, but it has been arranged to provide a demonstration of an employee conference before a group of men especially interested in this method.

For next year it is recommended that the work be divided among a number of subcommittees, each of which takes a phase of the relations of the worker. It also was suggested that instead of continuing the annual training course in connection with the convention, several series of conferences be held at central points in various sections of the country at convenient times. The exact character of these conferences was not determined, but it was suggested that one group be for training leaders for foreman conferences and another for training leaders for salesmanship, public contact or service-improvement conferences of car men and other employees not of supervisory rank.

The appendix of the report contains an article by M. B. Lambert on "Selling the Executive on the Importance of Employee Relations Work." Another appendix gives a complete list of books and articles which have appeared recently on topics bearing directly or indirectly on employee relations. This list was compiled by Henry H. Norris of the committee and Lewis A. Armistead, librarian, Boston Elevated Railway.

13. G. A. Richardson, Street Traffic Economics.
14. E. F. Wickwire, Manufacturer's Contact.
15. F. R. Coates, Co-operation with State and Sectional Associations.
16. Dr. Thomas Conway, Jr., National Relations Subcommittee on Depreciation.
17. Barron Collier, Publicity.
18. R. R. Bradley, Interurban Legal.

PUBLICITY

TRAFFIC congestion relief has been the subject on which this year's committee on publicity concentrated. The outstanding feature of this work was the inauguration and regular distribution of a news service entitled "National Traffic Notes." About 1,500 words are sent out about every ten days to all member companies. This is a national summary of traffic congestion relief news obtained through reading prominent newspapers throughout the country and other sources of information.

Supplementing this news service

Digitized by Google

has been a series of posters dealing with traffic congestion which have emphasized the point that public transportation vehicles are the most economical users of street space. Samples of posters are shown in the report. One series includes "stop" and "go" signals with a few pointed suggestions to prospective riders pointing out the advantages of street car service. Another series takes up traffic congestion and shows the futility of blocking the streets with parked automobiles. Other posters have been prepared on special topics for various purposes, including appeals to trainmen.

In order to combat misinformation which has been circulated about the country, the committee prepared a leaflet entitled "The Truth About Electric Railway Abandonments." This leaflet told briefly and truthfully the abandonment situation and also emphasized the unfairness of some newspapers in stressing small town abandonments as being of major importance.

A number of other campaigns were carried on during the year, including the reprinting of a number of addresses which have been made before the American Electric Railway Association and other bodies, and the 10-to-4 shopping campaign. Several new series of advertisements have been prepared for use by electric railways during the year, motion picture films have been distributed and there are now about 30 reels available covering seven subjects. New scenarios are now being prepared.

Resolutions on the Death of

Nicholas F. Brady

YOUR committee appointed to draft a memorial to the late Nicholas F. Brady presents, with recommendation for its adoption, the following:

Men in the utility field and in public life were greatly affected at the news of the death on March 27 of Nicholas F. Brady. In his death there passed a national figure—a man of outstanding business attainments, one wise in his benefactions, a devoted churchman, wide in his sympathies and considerate by his tolerance. As for the utility industry, his death removed one of its stanchest adherents. Modest in demeanor, Mr. Brady worked unceasingly to the attainment of corporate projects, but he never lost sight of the human factor upon which they depend for success. Aside from the part that he played directly in the electric railway industry through his various directorships and as an active participant in the affairs of this association, notably as a member of the Advisory Council from its inception, he contributed liberally to the promotion of the humanitarian side through his sponsorship of the Brady Awards, authorized early in 1914 by the family of the late Anthony N. Brady, but subsequently modified to make them more inclusive and revived by him after the war-time period.

Lasting in their impress are these awards made annually by the American Museum of Safety of a gold medal, a silver medal, and a bronze medal to those electric railways which for the year of the awards were judged to have done the most in their respective classes to conserve the safety and health of the public and the employees.

But keen as was his interest in these awards, it was only one of the man's many activities. Never did he lose sight of the complementary aspects of capital and labor. And nowhere was his appreciation of the responsibility of his stewardship better illustrated than the work he did with the National Civic Federation. High corporate, civic and spiritual honors were his because he built up character as well as riches. His corporate work, his benefactions and his humanitarianism proclaimed the man. In his death the American Electric Railway Association lost a wise counselor. It desires now publicly to acknowledge its debt to a benefactor by entering this resolution on its records and directing that a copy of it be sent to his family.

Respectfully submitted,
LUCIUS S. STORRS, *Chairman.*
F. R. COATES,
GEORGE J. MACMURRAY,
Committee on Resolutions.

Many Engineering Committees Prepare Reports

COMMITTEE work of the Engineering Association has been proceeding steadily. Much of it has been in progress over a period of several years and thus it was possible to prepare reports for presentation at the convention. The following brief abstracts give a condensed summary of the work accomplished.

Chairmen of Engineering Association Committees

1. L. C. Winship, Heavy Electric Traction.
2. E. M. T. Ryder, Editing of Proceedings.
3. L. D. Bale, Engineering Manual; Subjects.
4. C. A. Smith, Electric Railway Journal Maintenance Contest.
5. F. H. Miller, Nominations; Program.

Heavy Electric Traction

FROM a review of manual section D 100-14, it appears that existing standards for pantograph trolley clearances have been materially outgrown. It is planned to make a study in co-operation with the American Railway Association leading to a revision of this manual section. A specification was submitted for stud terminal rail bonds, which was prepared jointly with a subcommittee of the electrical section of the A.R.A., and which has been approved by the principal manufacturers. The welding of third rails, together with the use of other substitutes for copper bonding, has received consideration and will be developed during the coming year.

Considerable comparative information on oil-electric locomotives has been collected. It also is hoped to prepare a tabulation of operating statistics for these locomotives, and material is now being collected. Further information has been collected on the subject of articulated train operation, and the data sheet giving information on the subject has been revised. This year the locomotive tabulation was given only for machines which were not incorporated in last year's report. It is the plan of the committee now to prepare a complete report on electric locomotives every fifth year only.

Power Division

Power Division Committee Chairmen

1. H. F. Brown, Ferrous and Non-Ferrous Materials.
2. A. J. Klatte, Trolley Voltage Surveys.
3. W. E. Bryan, Power.
4. H. W. Codding, Mercury Power Rectifiers.
5. J. F. Neild, Power Supply for General Purposes.
6. R. H. Rice, Power Contracts.
7. D. L. Smith, Catenary Specifications.
8. H. S. Murphy, Trolley Wire Wear.
9. J. W. Allen, Manual Review.
10. A. Schlesinger, Lightning Protection.
John Leisenring, Distribution System.
L. R. Wagner, Trolley Construction Specifications.

Manual Review—Several of the specifications of this division were reviewed and recommended for revision. An appendix gives considerable information on the subject of trackless trolley.

—❖—

Power Rectifiers—Further operating experience was tabulated and summarized, using the standard log sheet published in the 1928 report. Additions to the bibliography were made, bringing it up to date. It is stated that the installed capacity in rectifiers for the eight months from May 1 to Dec. 31, 1929, was 165,475 kw.

—❖—

Power Contracts—During the year the committee has given its attention to checking details of contracts obtained and preparing from outlines of what a power contract should be. Such an outline is presented as an appendix.

—❖—

Power Supply for General Purposes—Use of trolley voltage supply versus commercial current circuits for general illumination of electric railway properties, operation of shop tools, and miscellaneous requirements was studied. The lighting and motor application as used by various properties was reviewed. Data on lamps and lighting practice were submitted by lamp manufacturers and other information was obtained from tests conducted by operating companies. The committee concluded that from an engineering and operating viewpoint the use of commercial current circuits is desirable, while from an economic viewpoint it may be cheaper to use trolley voltage supply, although this should be balanced against the

Digitized by Google

greater efficiency and flexibility of the utilization of commercial circuits.

—❖—

Catenary Specifications—Proposed revisions of manual section D 102-29, specifications for overhead line material, were included, as were preliminary reports on the study of alloy and composite messenger cables and insulators for catenary construction. A revised tabulation of catenary installations using copper alloy and composite messengers was given showing details of construction used.

—❖—

Trolley Wire Wear—The study of trolley wire wear and breaks, with special reference to breaks due to causes other than normal wear, was continued. It was treated in detail and constitutes the body of the report. Statistical data relative to trolley breaks are brought up to date by including 1929 operating results, and a number of new comparisons covering the period 1922-1929. The committee recommended adoption as standard of the revised specifications for hard bronze trolley wire.

—❖—

Specifications for 600-Volt Overhead Trolley Construction—A progress report only was made. This committee is preparing a revision of manual section D 101-16, which it is planned to bring in conformity with the fourth edition of the National Electrical Safety Code.

—❖—

Lightning Protection—Revision of manual section D 204-15 covering lightning protection for car equipment, stations and line was proposed, as was a revision of manual section E 207-24, in so far as it relates to the same subject.

—❖—

Distribution Systems—Investigation of the comparative cost and reliability of overhead and underground direct current distribution systems was made. The report presents a tabulation which gives some interesting data on the subject. The advantages and disadvantages of the two methods of distribution are gone into in some detail.

—❖—

Ferrous and Non-Ferrous Materials—This report covers principally ferrous and non-ferrous materials used for overhead construction. An analysis was made of the various methods used for protecting ferrous materials, such as coating with other metals, painting, electroplating, and chemical treatment.

Rolling Stock Division

Rolling Stock Division Committee Chairmen

1. H. H. Adams, Car Design.
2. H. S. Williams, Noise Reduction.
3. T. H. Nicholl, Rolling Stock.
4. P. V. C. See, Motor Coaches.
5. Hugh Savage, Current Collecting Devices.
6. W. T. Vivian, Limits of Wear.
7. R. W. Cost, Lighting.
8. J. H. Lucas, Lubrication.
9. E. J. Jonas, Fire Hazards in Shop Practices.

W. C. Bolt, Manual Review.

Motor Coaches—Due to the rapid changes of the industry the committee made no effort to standardize coach design. It did, however, draw up a code for making static tests of bus bodies, which is included as an appendix. It is also working on the determination of how frequently buses should be overhauled. Specifications for motor coach lubricating oils were proposed. Maximum possible rates of retardation were studied, and a tabulation showing the length of life obtained with various brake linings by the Cleveland Railway was included as an appendix.

—❖—

Car Design—A study of car equipment with special reference to appearance, comfort, ventilation and convenience was continued. Particular interest centered around the tests of several types of car trucks. These tests, which were begun more than a year ago, were continued. Charts showing the results up to the present are incorporated in the report.

—❖—

Lighting—Studies on the subject were continued during the year. Investigations were made on the use of dash illuminating headlights. Recommendations were given on interior color finishes for cars, burning position of lamps and the prevention of reflections on the windshield of the car due to the interior lighting. Recommendations were also made on the installation of lighting fixtures under interior baggage racks of motor coaches.

—❖—

Lubrication—Four reports of experimental work being done in connection with the use of light viscosity oils have been received by the committee. Since there was considerable variance of opinion, the committee has presented a report of progress only and has not made public the data received.

—❖—

Fire Hazards in Shop Practice—Study of fire prevention with special reference to spraying nitrocellulose lacquer and other inflammable finishing materials used in railway car painting was continued. It was pointed out that certain of the rules of the N.F.P.A. are inconsistent.

—❖—

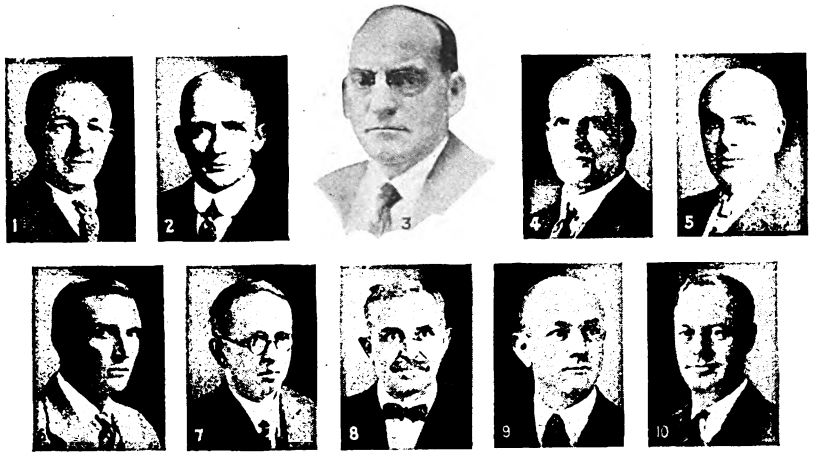
Noise Reduction—Further tests were made on a new type of cushion car wheel and comparisons made with a standard car wheel. These showed the improvements as regards noise obtained by use of the cushioned wheel. Tests were also made to show the value of celotex as a soundproofing medium compared with felt.

—❖—

Limits of Wear—An effort was made to arrive at some reasonable limits of wear on car journals, journal boxes, bearings and pedestal guides, both from the standpoint of the operator and from calculations. Maximum allowances have been selected which would not permit trucks and axles to rotate through a sufficiently large angle to allow the wheel flanges to drag on the rail. Definite limits of wear for railway motors and truck parts were recommended.

Digitized by Google

Way and Structures Division



Way and Structures Division Committee Chairmen

1. C. L. Hawkins, Track Construction.
2. E. M. T. Ryder, Special Trackwork.
3. C. A. Smith, Way and Structures; Wood Preservation.
4. C. H. Clark, Track Gage.
5. C. F. Gailor, Arc Welding.
6. S. C. Baker, Pavement.
7. H. S. Williams, Rail Corrugation.
8. C. A. Alden, Rails.
9. W. R. Dunham, Jr., Manuel Review.
10. M. W. Rew, Motor Bus Garage Design.
J. I. Catherman, Weed Elimination.
P. A. Kerwin, Alloy Steels for Special Trackwork.
P. J. Mitten, Wheel and Rail Contours.
W. A. Underwood, Foundations for Special Trackwork.

Manual Review — Recommendations were made to bring manual section W 25-23, specification for steel track spikes, in line with the latest specifications of the A.S.T.M. on the same subject. A change of manual section W 11-21, standard dimensions in switches and mates, was also recommended.

—◆—

Special Trackwork—Study of the design of tongue switches was continued. Designs were submitted with the report for a 75-ft. lateral, a 100-ft. equilateral, and for 9 in. deep work. A design for expansion joints and girder rail to be used in paved track was worked out but was not submitted as the committee desired also to work out a design for use in open track before reporting.

—◆—

Wheel and Rail Contours—A study of cylindrical wheel treads versus conical wheel treads in conjunction with flat head versus curved head rails was taken up. The committee has attempted to determine the reason for the use of a conical tread, to locate properties where a cylindrical tread has been tried, and to obtain information as to the results of such trials. The history of the conical tread was traced from the earliest days of railroads. While only one American electric railway property was located on which cylindrical treads are used, there are several in Europe.

—◆—

Wood Preservation — Specifications for the maintenance of pole timber and structures were presented. Further studies of the actual economies obtained through the use of treated timber were reported on. The study of wood preservatives other than creosote and zinc chloride is becoming more important, and it was continued. Possibilities of a combination preservative and fire preventive treatment for timber was given consideration. It is believed by the committee that with increased use, the relatively high cost of the fire-proofing treatment can be reduced. Preservative treatment for timber for use in car construction and maintenance was discussed.

—◆—

Arc Welding—Studies were made of various types of welding rods. A report was submitted giving proposed rules and instructions for training welding personnel. The committee also has given considerable thought to the collection of all available welding information which would be of any interest or use to electric railway employees.

—◆—

Alloy Steels for Special Trackwork—A group of tests was undertaken on surface welding of the three types of alloy steels now in use in special trackwork and to complete the work started last year in the investigation of thermit welding of chrome-nickel steel. A detailed description of the tests and the results obtained is given. The results of the several tests on surface welding of alloy steel were averaged and tabulated so that a comparison may be made conveniently and conclusions drawn. Another subcommittee developed a method for making wear measurements on individual pieces of special trackwork installations, so that all wear data should be recorded on a comparable basis. On the subject of heat-treated rail and intermediate manganese rail, it is stated that these materials offer interesting possibilities along the line of increased hardness, wearing qualities and resistance to rail corrugation.

—◆—

Pavement—It is believed that in view of the large expenditures for paving and of the increasing demands of vehicular traffic and increased cost of this part of the track structure, up-to-date information should be secured and made available to way engineers.

—◆—

Motor Bus Garage Design—A proposed outline of operating bus garage layouts was made, so that the operator may determine from it the various elements that are necessary in producing a satisfactory garage for bus service. It was recommended that the outline be approved as recommended practice for inclusion in the Engineering Manual.

—◆—

Rail Corrugation—A voluminous report was presented. It contains a collection and study of data pertaining to deflections under load and of the computed probable vibrations resulting from these deflections. The study shows that paved track is much stiffer than open track, and that in paved track the natural period of vibration is a probable contributing cause to rail corrugation. A short study of car nosing, together with a presentation of the data which the committee has collected, was made. Indications are that the effects of nosing may momentarily increase wheel loads by as much as 50 per cent. The report also includes summaries of the work done by the Canadian and the International Association committees on the same subject.

—◆—

Rails—Branding rails was discussed, and it was recommended that the subject be continued. Manual section W 16-24, specification for carbon steel rails of standard section, was reviewed and was submitted to the association for letter ballot. The relation between rail wear on a given section of track approaching stops

Digitized by Google

and between stops was studied to develop the connection between the amount of such wear and the volume of traffic, weight of equipment, rate of speed, etc. Fishing between the association's standard 7-in., 122-lb., grooved girder rail and the standard 7-in., 140-lb., girder guard rail was investigated.

Purchases and Stores Division

Manual Review—Several revisions of the Engineering Manual sections dealing with this subject were proposed. No changes are recommended in the classification of scrap material. The committee has prepared an index for the A.E.R.E.A. classification for materials and supplies. This is submitted as an appendix.

—◆—

Investments in Materials and Supplies at Cost of Operating Stores—A study was made to determine what is included in the account of materials supplied by the various member companies, what is charged to the account of stores expenses, what is the relation of stores expenses to gross earnings and other items, and what are the physical or operating circumstances which have a special influence on the subject. A questionnaire was sent out and replies are now being received. It was not possible to draw deductions from these in time for the convention.

—◆—

Standardization and Simplification of Stock—This committee has only recently been organized and arrangements are being made to obtain information on the subject.

—◆—

Materials and Supplies Control—The importance of proper control of stocks was stressed by the committee. Recommendations were made relative to proper methods of handling stock.

1. C. A. Harris, Standardization and Simplification of Stock.
2. W. E. Scott, Unit Piling and Standard Packages.
3. A. L. Fischer, Purchases and Stores.
4. W. S. Stackpole, Stores Investment and Costs.
5. A. A. Ordway, Pricing Methods and Records.

7. E. F. Kelley, Material and Supplies Control.

Purchases and Stores Division Committee Chairmen

T. & T. Committees Active

FIVE committees of the American Electric Railway Transportation and Traffic Association were continued during the past year for further study, research and collaboration. The available time for study was foreshortened but all of the committees made real progress in the subjects assigned. A sixth committee, covering the subject of operating economics, was created in the belief that an assignment of this scope would be beneficial and profitable. This report, along with five others that were completed, are herewith presented.

TRANSPORTATION EMPLOYEE

ANALYSIS of the transportation job, with the correlated subsequent supervisory and employee training, and a study of proneness to accidents are the items to which special attention is given in the report of this committee. The study of accident proneness covers several factors affecting efficient operation, although it is recognized that accidents comprise the more definite unit for measuring the faults. In seeking the fundamental cause for this proneness, the committee found a need for improved selection of trainmen and coach drivers, proper choice of the supervisory employee, and better training of both.

For the subject of accident proneness the committee concludes that there is definite need for intensive supervisory training and job analysis, that training should follow job analysis, and that selection and training of employees should be given greater study.

Under selection of the transportation employees, the committee discusses the preliminary interview of applicants, high physical standards and testing applicants for proneness to inefficiencies. A good supervisory staff, according to the committee, should be made up of high-grade men, properly trained.

MOVEMENT OF THE VEHICLE

COMMUNITIES and transportation agencies are more keenly aware than ever before of the fact that increasing private automobile usage presents a great and permanent problem. In this report the committee signalizes the work of the electric railways in solving the problem and analyzes the private automobile, parking, signals and traffic control, and equipment.

Under the first subject, the private automobile, the committee concludes that the most severe aspects of automobile competition have not been felt by collective transportation facilities and that the future may show a similar distribution to that now found, with some probable shifts toward collective transportation, with increases in street congestion and with improved transportation methods.

In the section devoted to the parking problem, the committee holds that parking is a privilege that may be tolerated where it does not interfere. It should be regulated to promote safety and an equitable distribution of space.

SMALL CITY OPERATION

THE report of the committee on small city operation outlined the procedure followed in securing additional data and analyzing the individual subjects of operating methods, merchandising, competition, bus substitution, franchises, operating economies, taxation and financial structure.

Questionnaires covering these were sent out during the year and the re-

Digitized by Google

sults interpreted at a three-day session. Conclusions arrived at in this meeting formed the major part of the committee's report. Among the significant statements were: Properties where most attention has been given to prices and selling service have obtained the best results; transportation must be supplied in the form in which the public wants it and at a price which is competitive; merchandising must go farther than advertising, the entire organization must be groomed to sell the service; buses offer several advantages which must not be overlooked; results of several companies indicate it is possible to adjust operating expenses to a very low level of earnings.

"There is no magic formula for the success of the small-city transportation property," the report concludes; "Individual conditions are controlling and must be expertly analyzed. The management cannot miss a single opportunity to provide joint service, secure added economies, or improve operating conditions. The greatest need is for skilled merchandising and all that is implied by it."

OPERATING ECONOMICS

FIVE broad subjects are covered by this committee: (1) Those operating practices which have been found beneficial on one or more properties, (2) use of one-man cars, (3) substitution of buses for street cars, (4) business-getting, and (5) fares.

In analyzing operating practices the committee sets forth those applications of modern methods and practices which will, first, increase the gross revenue of the operating company, and second, decrease the operation of maintenance costs.

Some companies have succeeded in stopping the annual decline, and in several outstanding examples have actually increased their riding and revenue during the past few years. The ways and means of accomplishing this satisfactorily are listed.

The operating practices which have resulted in decreased cost for operation and maintenance, as listed in the report, are those which, because of the fact that the individual saving may be relatively small when expressed as a percentage of gross revenue, are frequently overlooked but which, taken as a whole, represent a substantial saving to the industry.

On the subject of one-man cars, the committee expresses the opinion that the substitution of one-man cars for two-man cars has become more than a trend and that there are very few, if any, street car lines, except perhaps in the very largest cities, that cannot be successfully operated with one-man cars.

Chairmen of Transportation and Traffic Association Committees

1. C. W. Wilson, Movement of the Vehicle.
2. W. H. Boyce, Nominations.
3. C. A. Smith, Way and Structures; Wood
4. J. R. Ong, Operating Economics.
5. A. C. Spurr, Small City Operation.
6. L. C. Datz, The Equipment.
7. C. D. Smith, Transportation Employee.

W. W. Holden, The Passenger.

For the purpose of its study of the economics of bus substitution for street cars, the committee cautions against the comparison of modern buses and old-fashioned street cars, and suggests that an estimate be made of what savings in operating costs could be made by the use of modern cars.

To determine the extent to which aggressive merchandising methods are now being employed, a questionnaire letter was sent out. A decided declaration was made by many of the companies that a high quality of service must be maintained before results can be obtained from merchandising methods.

The study of fares was confined to an examination of the trend in revenue passengers in eight cities of the United States, each with more than 500,000 population, from 1926 to and including 1929. The results are presented graphically and analyzed in some detail.

THE PASSENGER

DETERMINING the education of the public in general as well as the patrons of public transportation toward the service which electric railways are rendering was considered a necessary field of investigation by this committee. Accordingly it organized and started a plan of research to find out why people use or do not use public transportation. This might be termed a quantitative or market analysis.

To establish a scientific and uniform method of making market analyses the electric railways selected a man with considerable experience in this work, Dr. W. J. Reilly, to visit a number of different properties and to assist and instruct them in the making of such an analysis. The plan is for Dr. Reilly to spend a period of from two to four days in instructing the local men in the methods of securing information and analyzing results. A sufficient number of companies accepted the plan to assure its accomplishment, but the work had not progressed sufficiently at the time of the report to present the final results.

EQUIPMENT

THE effect on revenues and operating expenses of new and rehabilitated cars; the size, type and character of units most suitable for various classes of service, and the accessories necessary for the safe and convenient operation of buses and trolley buses, are the individual subjects covered by the committee on equipment.

The first subject is divided into two parts, the effect on revenue, and the effect on the maintenance and operation accounts.

The facts developed by a study of individual cases where new cars were substituted for older equipment, together with the general comparison of 81 companies, 41 of which had new cars, admits of but one conclusion—new cars or cars that have been modernized increase passenger revenue by an appreciable per cent.

It is claimed that (1) operation of light-weight, modern cars shows a saving in power; (2) new cars increase schedule speed; (3) operation of modern cars reduces platform costs; (4) maintenance of modern cars is not only less for the first few years but also remains lower than for the old type of cars; (5) lighter cars show a saving in maintenance-of-way; and (6) safety features of new cars result in fewer accidents.

The recommendation is made on bus equipment that standard heating and ventilating systems and standard accessories be developed as parts of body design.

Digitized by Google

ACCOUNTANTS' and CLAIMS Associations Active in Committee Work

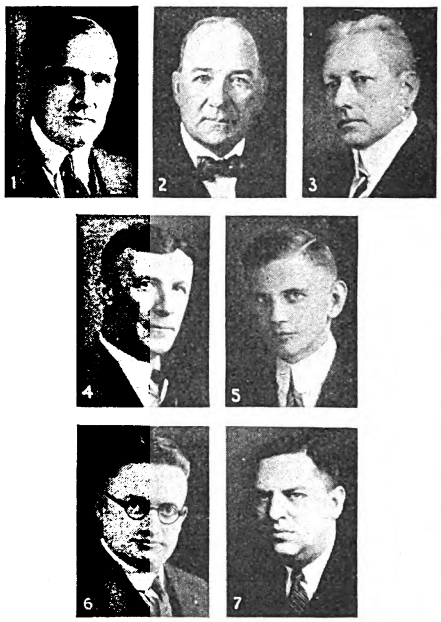
BOTH the Accountants' Association and the Claims Association committees prepared useful reports during the year. The former association completed several investigations which could not be finished in time for the Atlantic City convention last fall, at which time only reports of progress were made. The Claims Association continued with the same committees which have been functioning for some time.

Abstracts of the reports made public are published in the following paragraphs.

STANDARD CLASSIFICATION OF ACCOUNTS

DURING the past few years several interpretations of interest have been issued by the bureau of accounts of the Interstate Commerce Commission, and as these interpretations have not been published, the committee's report consisted principally of an appendix in which these rulings were set forth in detail. In the matter of the "unit of property," it has been ruled that the term should be restricted to property items the cost of which are ordinarily recorded separately in the property accounts. An important section of a continuous structure should include all of the elements of that particular structure and should not be applied to only one factor of the same. For instance, the complete electric motive equipment of a car should be considered a unit. Rails and paving are but factors of a continuous structure, and the accounting pertaining to the replacement thereof, where betterment is involved, is specifically provided for in the interpretations. The report of the committee, together with the appendix, should do much to clarify many disputed points in accounting procedure.

With a view to ascertaining the extent to which its recommendations had been adopted, the subcommittee on bus accounting had circularized the industry with the aid of the association's headquarters staff. From the replies received it would appear that the classification, slightly modified, is being adopted by a great majority of member companies, as well as by a considerable number of state regulatory bodies. The returns indicate that there is a heavy preponderance of opinion in favor of setting up a separate group of accounts for retirement expenses, but opinion on rentals was about evenly divided. Preliminary discussions have been held with the bureau of accounts of the Interstate Commerce Commission looking toward the promulgation of a classification for motor bus operating companies by that body. A mutually satisfactory understanding appears to have been arrived at, and a classification has been tentatively framed which will be in harmony with the committee's standard classification, as well as with that adopted by the National Association of Railroad and Utilities Commissioners.



Chairmen of Accountants' Association Committees

1. **Walter Shroyer**, Freight Accounting.
2. **T. P. Kilfoyle**, Nominations.
3. **M. W. Glover**, Standard Classification of Accounts.
4. **H. R. Bowie**, Stores Accounting.
5. **R. G. Smith**, Budgetary Control.
6. **W. L. Davis**, Representative at Accountants' Association at Annual Convention of National Association of Railroad and Utilities Commissioners.
7. **E. A. Tuson**, Bus Accounting Subcommittee of Standard Classification of Accounts; Fare Collections.

R. O. Crowe, Subjects.

BUDGETARY CONTROL

THE purpose of the budgetary control committee has been to determine the extent to which budget systems are now being used by member companies, and to devise a standard form of budget procedure in case there should appear to be any need for it. A widely circulated questionnaire was responded to by comparatively few companies, but the replies received indicated that a considerable number of properties already have budget control of revenues, operating expenses, cash requirements, taxes, and construction expenditures. The general impression gained from the replies returned was that the companies making use of the budget system find it extremely helpful and have experienced no disadvantage other than the expense of maintaining the necessary records. It is, perhaps, significant that only two companies discontinued budget systems after they had once been established.

Of the 93 companies replying to the questionnaire, 54 indicated that a further detailed study by the committee should be recommended. Reference was also made in a considerable number of replies to the excellent work of a similar committee of the National Electric Light Association, with the recommendation that if further study is to be carried on by the committee, the work of the N.E.L.A. committee should be carefully studied.

BUS ACCOUNTING

SINCE reporting to the last convention, the committee has undertaken the circularization of the country, first, to obtain accurate information as to the use of the association's bus classification; second, the extent of its official adoption by regulatory bodies; and, third, the attitude of bus operating companies toward the changes proposed in the classification as to rentals and retirement expenses

Digitized by Google

in the committee's reports to the last two conventions.

Information has been received from all but three states, and it has been found that the committee's classification, slightly modified in some instances, has been adopted by Maryland, New Jersey, Missouri, Vermont, Georgia, Oklahoma, Alabama, Florida, Wisconsin, Tennessee and the District of Columbia. Minnesota also accepts reports filed upon the basis of this classification as well as another classification promulgated by the state.

Of the other states, only Pennsylvania and California have adopted classifications designed to cover major bus operations, although eleven other states have classifications for the use of small operators. Three states, Texas, Iowa and Wyoming, were not heard from, twenty have no standard classification, and Delaware has no state regulatory body.

The committee finds further that of the member companies circularized nearly all use its classification except the Pennsylvania and California companies.

The response to the inquiry for opinions on the proposed changes in the classification resulted in a heavy preponderance in favor of setting up a separate group of accounts for retirement expenses. The vote on rentals was evenly divided.

Preliminary discussions have been held with the bureau of accounts of the Interstate Commerce Commission looking toward the promulgation of a classification for motor bus operating companies by that body. A mutually satisfactory understanding seems to have been arrived at and a classification has been tentatively framed. This classification will be in harmony with the standard classification, which has already been adopted by the National Association of Railroad and Utilities Commissioners.

SAFETY

IN PRESENTING its report wherein it was recommended that the safety committee of the Claims Association be discontinued, the committee took the view that the interest of the Claims representatives in the subject of safety arise only after the occurrence of accidents, and that accident work is usually in the hands of specialists, in consequence of which there was no need for a safety committee organization within their association. Those members of the association who are taking an active interest in accident prevention work upon their properties, according to the report, attain success only where managements and other operating departments give wholehearted co-operation in such efforts. The committee held, further, that there can be no success in any accident prevention work without the co-operation of managements and other operating departments.

The committee made the further recommendation, however, that a safety committee be appointed by the American Association, with a membership to be composed of representatives of managements and the several operating departments, including the claims departments. Such a committee, according to the report, would limit its activities to actual safety matters, such as legislation in the interest of safety, dissemination of information regarding safety devices, standardizing protection for crossing and train operation, etc., omitting further consideration of such matters as uniform classification, uniform accounting, chargeable and non-chargeable accident definitions, and other such matters not actually concerned in real accident prevention.

CLAIMS DEPARTMENT PRACTICES

THE committee on claims department practices pointed out in its report that the non-uniformity of practice makes it impossible for properties to compare results and thereby profit by an interchange of information. A recommendation put in the form of a motion for the appointment of a representative committee to standardize all claims department reports was unanimously passed.

Considerable preliminary work was done by the committee and a questionnaire was sent out. Replies were received from a considerable number of representative companies, but it was felt that only a report of progress should be made at present.

Downtown San Francisco

Chairmen of Claims Association Committees

1. Wallace Muir, Nominations.
2. J. S. Kubu, Uniform Negligence Law.
3. J. H. Handlon, Subjects.
4. B. C. Wood, Claims Department Practices.
5. P. W. Klabunde, Safety.

UNIFORM NEGLIGENCE LAW

IN ITS report on the uniform negligence law the committee made it plain that it had confined its endeavors to an attempt to determine the constitutionality of the imputed negligence act, as drafted by a previous committee. Consultation was had with counsel, not alone in the street railway industry but from the steam railroads and the insurance companies as well. The general opinion was that the constitutionality of such a case had practically been established in a recent decision of the United States Supreme Court involving a Connecticut statute which, in effect, released owners of motor vehicles from responsibility for injuries to passengers therein. There remained, however, the question of political interference with the passage of such an ordinance, this being a debative point the committee was unable to solve.

Although commendable progress had been made in classifying procedure, the committee on claim department practices was not in position to render a final report, and asked that it be continued for another year.

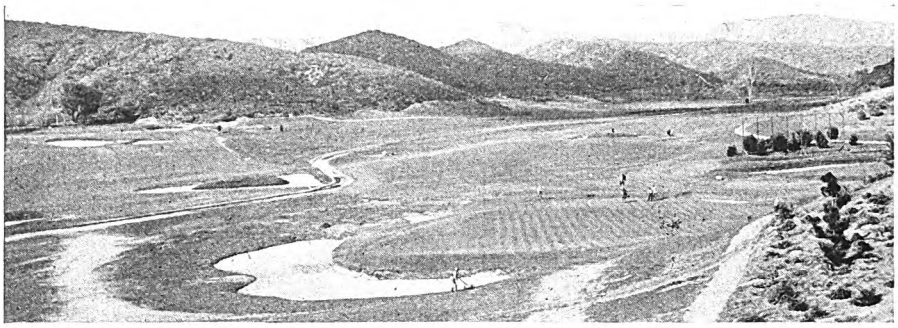
How the Convention Guests

Were Entertained



Many delegates took advantage of the opportunity for golf

EXTENSIVE planning on the part of the entertainment committee provided a very complete program for the A.E.R.A. delegates and their families while in the convention city and in southern California. Interesting events were scheduled for almost every time of day, and many availed themselves of the opportunity of combining pleasure with business.

Numerous automobile trips, special concerts in the hotel lobbies, and golf were scheduled for every day of the convention. Golf privileges at the principal San Francisco Clubs were extended to registered delegates of the convention.

Automobile trips were made on Sunday afternoon and Wednesday to interesting points in the metropolitan area of San Francisco. The Wednesday trip, planned especially for the ladies, included Taits-at-the-Beach where the party had luncheon. Leaving this interesting spot, the party followed the Skyline Boulevard down the Peninsula to Stanford University, where the famous Stanford Memorial Chapel, the home of President Hoover and the University's huge stadium were viewed. From here the group went to the beautiful Los Altos estate of Mr. and Mrs. Paul Shoup, where tea was served.

On Monday afternoon an informal reception and tea for the ladies was given at the Laurel Court of the Fairmont under the sponsorship of the hostess committee, headed by Mrs. Paul Shoup. In the evening the Advisory Council banquet was held.

Tuesday morning was set aside for shopping tours for the ladies of the convention. Many took advantage of this opportunity to visit some of San Francisco's leading shops, including those in Chinatown. In the afternoon two interesting features were enjoyed, an inspection of the 600-ft. California relief map on the second floor of the Ferry Building, and a boat trip on the San Francisco Bay, extended through the courtesy of E. H. Maggard, vice-president and general manager of Southern Pacific-Golden Gate Ferries, Ltd.

One of the outstanding social events of the convention was held Tuesday evening in the Venetian Terrace of the Fairmont Hotel, portraying "A Night in Hawaii." Nothing was left undone to place the guests in this atmosphere. The feature of the evening was the entertaining by Johnny Nobles' Orchestra from the Royal Hawaiian Hotel at Honolulu and the Hawaiian Girls' Glee Club, featuring Lani Ruttmann, hula dancer in "White Shadows of the South Seas."

An atmosphere of the days of Old California just before and during the discovery of gold in 1849, was provided at the grand ball, held at the Fairmont Hotel Wednesday evening. The decorations were particularly novel and fitting for the occasion and lent much to the effectiveness and enjoyment of this event. During the evening a number of special dances were given, including the tango, a cakewalk, a Spanish waltz, and a spirited adagio. Music for both the Grand Ball and a "Night in Hawaii," was furnished by Anson Weeks' Orchestra of the Hotel Mark Hopkins.

Mention should also be made of the entertainment provided for the delegates en route. The White Special, leaving Chicago on the evening of June 17, made stops at St. Paul and Portland. Many availed themselves of the opportunity to see the Twin Cities in a bus ride from St. Paul to Minneapolis. At Portland, the party was royally entertained for a full day by the Pacific Northwest Public Service Company. A 200-mile automobile trip along the Columbia River scenic highway to Hood River occupied most of the day. On the return, the party stopped at Eagle Creek for a mountain trout barbecue.

The Red Special party was entertained at St. Louis, Kansas City, Colorado Springs, and Salt Lake City. At the first city, the delegates were taken to inspect the Lindbergh trophies and to hear part of the Municipal Opera program. At Kansas City the delegates were given a breakfast at the Kansas City Athletic Club and shown the points of interest in the city.

Near-by spots of scenic beauty were visited at Colorado Springs via automobile. A five-hour stop was made at Salt Lake City, permitting the party to inspect the trolley bus system there and view several interesting places. The Blue Special was scheduled for making the trip in a minimum of time and had no stopovers.

Friday found a number of delegates at Del Monte for the A.E.R.A. Pebble Beach eighteen-hole medal handicap golf tournament. Ephraim Brown, Ohio Brass Company, won with 79. Others spent the day at the Yosemite Valley.

Almost 300 enjoyed the tour of Los Angeles and vicinity on Saturday. Among the places visited in the morning were the city hall, Elysian Park, Luna Zoo, San Gabriel Mission, Pasadena residential districts and Glendale. At noon members of the party were entertained at Fryman Rancho with an old fashioned Spanish barbecue. Individual buses then went to the motion picture studios where the party saw how sound films are made by Metro-Goldwyn-Mayer, First-National, Warner Brothers and Pathé. The trip was concluded with a visit to the beaches, to Beverly Hills and to the outlying residential suburbs.

That evening there was a farewell reunion in the nature of a dinner dance at Brandstatter's famous cafe, Montmartre, Hollywood, participated in by 34 members of the party.

NEWS *of the Industry*

LATE NEWS

Cleveland, Ohio—Opening of through railroad service at Cleveland's new Union Terminals, a $200,000,000 development, was celebrated June 28.

✦

Seattle, Wash.—The Board of Public Works will call for bids for five trackwork layouts for the municipal railway department to cost about $60,000.

✦

East St. Louis, Ill.—Following a hearing on June 17, the Illinois Commerce Commission has under advisement the application of the East St. Louis Railway for a straight 10-cent car and bus fare. Under the new fare the company hopes to get $85,000 a year additional revenue. This would enable it to earn 4½ per cent on its valuation. The city opposed the application.

✦

Paterson, N. J.—The Public Service Commission has approved substitution of buses for trolleys on the run of Public Service Co-ordinated Transport between Paterson and Haledon.

✦

Detroit, Mich.—The proposal to build street cars in its own shops so that employees in the shops of the Municipal Railway may get more than four days' work a week has been rejected by the Detroit Street Railway Commission.

✦

Philadelphia, Pa.—The City Council committee on transportation has approved construction of a $29,000,000 extension of the Market Street subway from Twentieth Street to 46th Street. The measure calls for two tubes under the Schuylkill to replace elevated structure. The committee also has approved the construction of a high-speed line under Locust Street, from Eighth to Eighteenth Streets.

✦

St. Louis, Mo.—The recent survey of downtown traffic conditions made by the St. Louis Public Service Company has revealed widespread violations of the parking laws in the congested districts.

✦

Danbury, Conn. — The Danbury Power & Transportation Company has purchased the White Line Bus Corporation, Inc., Bridgeport, Conn., and has petitioned the Public Utilities Commission for permission to discontinue trolley service between Wentworth Street and Bethany Chapel. A hearing on a petition providing for service by bus over that part of North Main Street was set for June 30. A 10-cent fare is asked.

✦

New York, N. Y.—Bids were opened June 28 by the Board of Transportation for construction of the seventh section of the new city subway system in the Bronx. The low bidder, at $2,691,028, was Di Marco & Reimann.

Voters Approve New Chicago Unification Franchise

$200,000,000 Must Be Spent Within Ten Years and $65,000,000 Within Three Years. 1,700 New Cars and 300 Buses on Program

CITIZENS of Chicago, by a majority of approximately five to one, on July 1, voted for the transportation ordinance, planned to relieve the congestion in the downtown districts, provide rapid transit to far outlying points and furnish transportation to districts heretofore practically isolated.

The ordinance provides for a merger of the elevated and surface lines and various feeder buses. Construction of two subways, through which the surface and elevated lines will enter the downtown district, will go far toward relieving the present undesirable congestion.

Seventeen hundred new cars, elevated and surface, and 300 feeder buses are also included in the program.

The ordinance requires the transportation companies to expend $200,000,000 in extensions and improvements in the next ten years, $65,000,000 of which must be spent in the first three years after its adoption and acceptance. Financial experts who assisted the city aldermen and lawyers in the framing of the ordinance, have stated that in their opinion the necessary money can be raised, as the financial setup is on a sound basis.

Chicago has talked for a quarter of a century on the need for subways in the downtown district to provide additional trackage. The ordinance provides for such subways to be built and owned by the city and operated by the transportation companies. As one commentator put it:

"Rapid transit is the greatest need of Chicago as the city extends its boundaries. It is essential for the people to be able to travel from one section of the city to another in the least possible time, and this service can best be rendered by consolidation of the transportation companies and the co-ordination of elevated, surface and bus lines, as provided in the ordinance."

COMING MEETINGS

July 10 — New York Railroad Club Annual Outing, up the Hudson on the Day Line steamer *Alexander Hamilton.*

July 17-18 — Central Electric Railway Association, the Breakers, Cedar Point, Sandusky, Ohio.

July 23-25 — Electric Railway Association of Equipment Men, Southern Properties, Nashville, Tenn.

July 24-25 — Central Electric Railway Accountants' Association, Cedar Point, Ohio.

Aug. 13-14—Wisconsin Utilities Association, Milwaukee, Wis.

Sept. 17-19 — Canadian Electric Railway Association, 26th annual convention, Ottawa, Canada.

Oct. 29-30—Iowa Electric Railway Association, Des Moines, Iowa.

Renewal of Toledo Grant an Issue

Six charter amendments, among them two aimed to cure defects affecting the street railway franchise renewal, will be submitted at the August primary election. If the charter amendments are carried, renewal of the Milner ordinance under which the Community Traction Company has been operating in Toledo, Ohio, for nearly ten years, will be submitted to electors in November. A provision now in the charter bars renewal of the ordinance except within a year of expiration date. The Milner plan was so drawn that, in case the grant is not renewed, it continues to govern for fifteen years, during which time the property is to be amortized. Another amendment will enable voters to give an exclusive franchise by vote. The present charter bars any exclusive franchise. Under terms of supplementary legislation, the Community Traction Company, now virtually has a monopoly of railway and bus transportation in Toledo.

Accountants to Meet at Cedar Point

Beautiful Cedar Point, near Sandusky, Ohio, will be the scene of the sixty-third meeting of the Central Electric Railway Accountants Association July 24 and 25. "The Breakers" will be the hostelry, and the session on July 25 will be held on the steamer *Chippewa* with luncheon at Put-In-Bay. There will be a dance every night and such other frivolity as golf, boating and bathing, to say nothing of the chances for hilarity at the Amusement Park. L. G. Tighe, president of the Central Electric Railway Association, will deliver the opening address. "Calendar Simplification" will be explained by M. B. Folsom, assistant treasurer of the Eastman Kodak Company, and "Freight Accounting—Your Problem and Mine" will be discussed by C. H. Sellman, auditor freight accounts, New York, Chicago & St. Louis Railway. Write the "Breakers" now for reservations!

LATE NEWS

(*Continued from Page* 486)

Oakland, Cal.—At a meeting of the directors of the Key System Transit Company on June 19, William P. St. Sure was elected a director to succeed the late B. W. Fernald. A. E. Nicoletti, assistant claims agent, has been made claim agent, to succeed Mr. Fernald. Perry Woodcock has been appointed assistant claims agent.

✦

Hartford, Conn. — The Connecticut Company has been authorized by the Public Utilities Commission to substitute service by bus for railway service between Middletown and Hartford. The buses will operate from Gold and Main Streets, Hartford, to the State Hospital for the Insane, Middletown, over a route slightly different from that proposed in the commission's order of April 22.

✦

Kansas City, Mo.—The Kansas City Public Service Company has passed the dividend on the $7 preferred stock due at this time.

✦

Watertown, N. Y.—The Public Service Commission has granted the petition of the Black River Traction Company to abandon 6.33 miles of its 11.33 miles of route in Watertown and the villages of Glen Park, Brownville and Dexter. It is probable that the company would have operated its line outside of the city for some time were it not for the plans of the State Highway Department to construct a state highway that would require the company to move its poles and tracks and to pave between the tracks at a cost of $77,932, an expenditure the company felt unwarrented.

✦

Glendale, Cal.—Application has been made to the Railroad Commission by the Glendale & Montrose Railway for authority to abandon operation of freight and passenger service between Verdugo Road on the south end, La Crescenta on the north, Eagle Rock City on the east, and Brand Boulevard, Glendale, on the west, and to cancel its contract for operation with Los Angeles & Salt Lake Railroad. Competition has made it no longer possible to operate profitably.

✦

Salt Lake City, Utah—Armed with a consent granted by the City Commission, the Utah Light & Traction Company has asked the Public Utilities Commission for a permit to install trackless trolley service on its Warm Springs line. Street cars will be operated as required to the present terminus of the Centerville line, and railway service will be continued to Warm Springs by way of the Center Street line.

✦

Tucson, Ariz.—Preparatory to asking a new franchise from the city, the Tucson Rapid Transit Company has filed for record an amendment to its articles of incorporation extending its corporate life for another 25 years. The company now operates railway lines to the university and through the southern part of the city in addition to bus service started in 1925 under a separate fifteen-year franchise from the city.

✦

Niagara Falls, N. Y.—Justice Ackerman in the Supreme Court at Buffalo has dismissed the application of Niagara Falls taxpayers for an injunction restraining the Public Service Commission from proceeding to fix fares on local lines of the International Railway, Niagara Falls, in connection with the recent contract between the city and the company providing for an 8-cent fare. Justice Ackerman ruled that the judicial district at Buffalo has no jurisdiction in the case. The commission now has the application of the railway for a higher fare here under consideration.

✦

Los Angeles, Cal.—The Pacific Electric Railway has applied to the Railroad Commission for permission to discontinue passenger service on its line between Santa Ana and Orange, stating that service by applicant and Motor Transit Company imposes unnecessary expense, especially as Pacific Electric Railway operations are conducted at a loss.

✦

Binghamton, N. Y.—The Public Service Commission on June 26 authorized the Triple Cities Traction Company to substitute buses for street cars on its Clinton Street lines in Binghamton and Dickinson. Buses to be installed, each carrying 25 passengers, will operate on the same schedule as the street cars. Approximately 3 miles of track will be removed under the substitution plan.

✦

Louisville, Ky.—As a result of sale of all power and substation operations by the Louisville Railway to the Louisville Gas & Electric Company, and entry of a 20-year contract whereby the railway will buy its power, 140 employees of Louisville Railway on July 1 automatically became employees of the Louisville Gas & Electric Company. A farewell dinner to all company power department workers was arranged by the railway on June 28, one group being dined at noon and the other in the evening. James P. Barnes, president of the company; Frank H. Miller, vice-president and general manager; Neil W. Funk, safety director, and Alfred Selligman, attorney, were among the speakers.

✦

Trenton, N. J.—The Public Utility Commission on June 28 ordered suspension for three months from July 15 of a proposed schedule of fares asked by the Public Service Co-ordinated Transport. The company, which is now charging a 10-cent cash fare and selling ten tokens for 50 cents, good on buses or trolleys, seeks to reduce the number of tokens to four for 25 cents. The board announces that time is desired to inquire into the reasonableness of such a rate.

✦

New York, N. Y.—The Transit Commission has postponed until Sept. 4 a hearing on the proposed removal of the Sixth Avenue Elevated line. The delay was granted at the request of Arthur Peacock, of counsel for the Interborough Rapid Transit Company, operator of the line and opponent of the removal.

✦

New York, N. Y.—The Union Motor Coach Terminal, successor to the Waldorf-Astoria terminal and managed by Fifth Avenue Coach Company, has been opened at 59-61 West 36th Street. Motor coach operating companies using the terminal are Gray Line Motor Tours, Inc., Fifth Avenue Coach subsidiary; the Greyhound Lines, the P. R. T. Lines, New England Transportation Company, and Champlain Coach Lines.

✦

Seattle, Wash.—Trackless trolleys will undoubtedly be tried in connection with the Municipal Railway. George B. Avery, utilities superintendent, is conducting an investigation and his final verdict is expected soon. An early proponent of trackless trolleys here was Roy E. Furse, railway superintendent. Councilmen Case and Laube have inspected the trackless trolley system in Salt Lake City and J. W. A. Bollong, city traffic engineer, has studied trackless trolley operation in Eastern cities, particularly the new installation in Detroit.

✦

Philadelphia, Pa.—On June 24 Deputy City Comptroller Wilson, Director Myers, of the Department of City Transit; Councilman Pommer, chairman of City Council's transportation committee, and W. K. Myers, vice-president of Mitten Management, were appointed a committee to consider and report on the method to be followed in arriving at a financial settlement for proposed municipal purchase of the Philadelphia Rapid Transit Company and its underlying systems.

✦

Erie, Pa. — The Erie Railways has asked the Public Service Commission for permission to abandon railway service in West 26th Street and the West Ridge Road. Through its bus operating subsidiary, the Erie Coach Company, the railway plans to operate buses over the route, between Perry Square and the village of Westminster, Pa.

✦

Detroit, Mich.—The Street Railway Commission has authorized Del A. Smith, general manager, to look further into a proposal through which the Frischkorn Realty Company offers to extend trackless trolley overhead construction in Plymouth Road 2 miles west of River Rouge Park, the present terminus. In return for service in the district, the company stands ready to finance the entire cost of the overhead equipment, estimated at $26,000.

✦

Toronto, Ont.—The City Council on June 15 chose the Transportation Commission, responsible for the operation of the local municipal railway and bus lines. It is to be composed of Fred Hubbard, formerly assistant general manager of the Toronto Railway; W. C. McBrien, a member of the Board of Harbor Commissioners; S. J. McMaster, whose name was rejected by Council on several occasions.

✦

Pontiac, Mich.—An ordinance to increase car fare in Pontiac from 7 to 8 cents has been passed by the local City Commission. The bus fare remains unchanged. The new fare schedule also calls for an increase in the price of tickets, from four for 25 cents and 17 for $1, to four for 30 cents and 15 for $1. A charge of 1 cent for transfers from street cars to buses also is allowed. No charge will be made for transfers from buses to street cars. The Eastern Michigan Railways operates here under a day-to-day agreement.

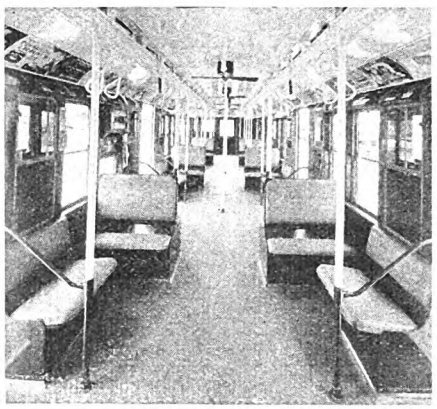
The four-door arrangement of New York's new subway cars is expected to expedite loading

New York Subway Cars Approach Completion

The first consignment of the 300 steel cars for use on the new subway lines of New York City will be delivered during the last week in July. The cars will be equipped with motors and other electrical apparatus at the city's new shops at 207th Street and the Harlem River. This work will cost $2,500,000, bringing the total cost of car construction and equipment up to $11,376,397, or about $38,000 for each of the 300 cars. The cars will be completed and equipped in ample time for thorough testing before they are placed in operation on the new Eighth Avenue line next year.

Four pairs of doors on each side of the car permit rapid ingress and egress in eight files, and it is believed that the time required for loading and unloading passengers can be cut 33⅓ per cent below the minimum on cars now in use here. The new cars will have no vestibules and special door-closing devices are expected not only to expedite loading and unloading but also to cut down the number of injuries to passengers. These devices make it impossible for passengers to hold up progress of a train by pushing the doors back as is now often done on Interborough cars.



Interior arrangement of subway cars provides ample standing capacity

Each of the cars will seat 60 persons and provide standing room for 220, giving a gross capacity of 280 persons for a 60-ft. car. The cars are 10 ft. wide and are expected to have 40 per cent more passenger capacity than the Interborough standard car.

Each car will have 22 electric lamps, each separately wired and not affected by mishap to any of the others. The cars will weigh 42 tons apiece, and each will contain 18,935 rivets, as well as nearly 2 miles of wiring.

Segregation of Akron Properties

In connection with the consolidation of companies in the Commonwealth & Southern group in Ohio, the Northern Ohio Power & Light Company has petitioned the Ohio Public Utilities Commission for permission to segregate its light and power business from its transportation business. This applies to its interurban as well as city lines.

Three companies, the Akron Transportation Company, the Northern Ohio Interurban Company and the Canton Traction Company, have been organized, or are in the process of organization, to take over the transportation business. All tracks, overhead distribution system, cars, buses and other transportation equipment used in furnishing railway and bus service in Akron will be conveyed to Akron Transportation Company subject to the present mortgage liens until paid or retired.

The same plan is to be carried out with reference to the interurban lines of the company and the Canton city system. In each instance Ohio Edison Company will hold the stock.

On July 1 the stockholders approved the consolidation of its power and light properties with those of the Pennsylvania-Ohio Power & Light Company, the Ohio Edison Company, the Akron Steam Heating Company, and the London Light & Power Company.

Unemployment Hurts Toledo Earnings

Operation of the Community Traction Company, Toledo, during the first five months of 1930 resulted in a net deficit of $72,890 as compared with the favorable balance of $95,284 for the similar period last year, after all charges under the Milner ordinance. Service cuts have been held to the minimum so that most of the economies have been from other sources. The drop in revenue from $1,766,995 for the first five months of 1929 to $1,435,751 for the similar period this year has been too much to absorb. Industrial unemployment has been largely responsible for the changed showing. The operating ratio this year is 78.518 per cent as against 71.323 per cent for similar period last year. Bus ratio is 83.048 per cent and railway ratio 76.741 per cent for the current year.

Conspectus of Indexes for June, 1930

*The three index numbers marked with an asterisk are computed by Mr. Richey, as follows: Fares index is average street railway fare in all United States cities with a population of 50,000 or over except New York City, and weighted according to population. Street Railway Materials index is relative average price of materials (including fuel) used in street railway operation and maintenance, weighted according to average use of such materials. Wages index is relative average maximum hourly wage of motormen, conductors and operators on 136 of the largest street and interurban railways operated in the United States, weighted according to the number of such men employed on these roads.

PERSONAL MENTION

C. F. Hirshfeld to Conduct Car Research for Industry

Detroit Edison official Selected as Engineer-Expert for Important Task by Presidents' Conference Committee of A.E.R.A.

APPOINTMENT of C. F. Hirshfeld as chief engineer of the Presidents' Conference Committee, intrusted with the work of expediting the development of the urban railway car, was announced at the meeting of the American Electric Railway Association at San Francisco. It is a most important post, but Mr. Hirshfeld has had a wealth of experience in conducting research projects.

After a thorough canvass of the problem, the committee unanimously decided that a knowledge of car building or the operation of railway properties was not a prerequisite to the position and might constitute a handicap. Rather the man needed, it was decided, was one with wide experience in handling research projects, an engineer-executive, and Mr. Hirshfeld was selected as the man who had demonstrated his ability to conduct large research problems and bring them to a successful conclusion.

As the address of Dr. Thomas Conway, Jr., abstracted elsewhere in this issue, makes plain, Mr. Hirshfeld is relying upon the active co-operation of railway master mechanics, of engineers and technicians of the car builders, of the makers of electric equipment and of braking apparatus and of other groups whose products enter into railway cars. The industry, through the association and especially through the Presidents' Conference, bespeaks full co-operation for Mr. Hirshfeld that worthwhile experiments with any new products may be so carried out as fully to determine their practical usefulness.

Mr. Hirshfeld has been chairman of the technical national section of the National Electric Light Association. He is chief of the research department of the Detroit Edison Company, with which his work has been of a varied character. In addition, Mr. Hirshfeld has conducted a general consulting engineering business. A native of San Francisco, he attended the University of California, from which he was graduated in 1902 with a B.S. in electrical engineering, three years later receiving the M.M.E. degree from Cornell University. From 1903 to 1914 he was a member of the engineering faculty of Cornell, starting as instructor in experimental engineering and ending as full professor of heat-power engineering, machine design, gas-power engineering, etc.

Mr. Hirshfeld has been extremely active in association work, having served as a member of various committees of the American Society of Mechanical Engineers and of the American Institute of Electrical Engineers, as past-chairman of the steam turbine and generator committee of the Association of Edison Illuminating Companies, and as past-chairman of the prime movers committee of the National Electric Light Association. He is the author or co-author of five books on engineering subjects.

Mr. Hirshfeld joined the Detroit Edison Company in 1913 and built up in that company the research department, of which he is chief. His work with the company has been of an extremely varied character, as problems come to the research department from practically all of the other departments of the company. He is particularly well known in the electrical field through his study on industrial electric heating, work started in 1914 and continued with interruptions ever since. He has also been active in rate controversies and in the rehabilitation and management of power plants.

Mr. Hirshfeld served during the World War as major and lieutenant colonel in the Ordnance Department of the United States Army.

C. F. Hirshfeld

Three Commercial Vice-Presidents for Westinghouse

Three new executive positions, the office of commercial vice-president, have been created by the board of directors of the Westinghouse Electric & Manufacturing Company.

C. E. Stephens has been selected to occupy the new position for the Atlantic division, with headquarters at New York City; N. G. Symonds for the central division in Chicago, and W. R. Marshall for the Pacific division at San Francisco.

All of the new commercial vice-presidents have been district managers and will continue the duties of that position, in addition to those of the new position.

W. R. Bell at Baton Rouge, H. C. Leonard in El Paso

W. R. Bell, since 1926 general superintendent of the El Paso Electric Company, El Paso, Tex., has been made general superintendent of the Baton Rouge Electric Company and the Louisiana Steam Products Company, Baton Rouge, La.

Mr. Bell will be succeeded in El Paso by H. C. Leonard, who has been in charge of the electrical department of the Virginia Electric & Power Company, Richmond, Va.

Mr. Bell has been employed by companies operating under the executive management of Stone & Webster, Inc., since 1906. He began in the accounting department of the Paducah Electric Company, working during vacations while attending college. Following his graduation from Rose Polytechnic Institute, Terre Haute, Ind., as electrical engineer, Mr. Bell accepted the position of assistant superintendent of the Baton Rouge Electric Company, later being made sales manager. Still later he was sent to Haverhill, Mass., as sales manager of the Haverhill Gas Light Company. In August, 1924, Mr. Bell was sent to El Paso as sales manager. He made a splendid record as head of the sales department and during his two years as sales manager in El Paso, the volume of appliance sales trebled, the sales floor space was doubled and the sales force was greatly enlarged.

Since becoming general superintendent in 1926, Mr. Bell has been closely identified with some of the most important developments ever undertaken by the company.

Mr. Leonard became associated with the Stone & Webster organization in 1919. He was a member of the group of engineers making an appraisal of the property of the Virginia Electric & Power Company. Upon completion of this work, Mr. Leonard was sent to the Boston office as designer. He remained in Boston only a short time until he was again sent to the Virginia Electric & Power Company, this time entering the engineering department.

Some time after his return to Virginia, Mr. Leonard was made electrical engineer in charge of design of the power station, substations and transmission lines. In 1927 he assumed charge of the electrical department of the company at Norfolk. He remained in Norfolk until early in 1930, when he was promoted and sent to Richmond, in charge of the electrical department of the company there.

Mr. Leonard is a native of Worcester, Mass. He was graduated from Worcester Polytechnic Institute with the degree of B.S. in electrical engineering. Following graduation, he entered the testing and engineering department of the General Electric Company, but he continued his studies at Union College, where he received a degree of M.S.

T. E. Thomas, traffic manager of the London County Council Tramways, London, England, has been appointed general manager to succeed J. K. Bruce, who is retiring on account of ill health. The salary is £2,000 a year, rising after four years by annual increments of £250 to £3,000. Mr. Thomas was formerly commercial superintendent of the Metropolitan District Railway and allied companies. He entered the County Council's service in 1917. He has recently been acting as general manager owing to Mr. Bruce's absence.

M. H. Frank Heads Wisconsin Association

New officers have been elected by the Wisconsin Utilities Association to serve from May 1 as follows:

President—M. H. Frank, assistant to the vice-president, Wisconsin Power & Light Company, Madison.
Vice-president—A. J. Goedjen, division manager, Wisconsin Public Service Corporation, Green Bay.
Treasurer—Ewald Haase, vice-president, Milwaukee Gas Light Company, Milwaukee.
Chairman Employees' Education Section—E. J. Steinberg, The Milwaukee Electric Railway & Light Company, Milwaukee.
Vice-chairman Employees' Education Section—R. G. Walter, Wisconsin Power & Light Company, Madison.

Other section officers are elected at separate conventions held during the year.

Mr. Frank has been manager of the Wisconsin Power & Light Company's Fond du Lac properties since 1918. After obtaining his electrical engineer's degree in 1915 he joined the Indiana & Michigan Electric Company, South Bend, Ind., as assistant construction engineer, where he built the 300-ft. Tainter gate dam and a 4,000-hp. hydro plant.

Mr. Frank remained there until 1916 as assistant engineer having charge of the operation of four hydro electric units, one steam plant and 75 miles of transmission lines. In that year, he became associated with the Galesburg Railway Lighting & Power Company, Galesburg, Ill., as operating engineer, where he laid out a 4,000-hp. steam plant and was in charge of the generation of both electricity and gas. After two years there, Mr. Frank went to Fond du Lac as manager for the former Eastern Wisconsin Electric Company, changed later to the Wisconsin Power & Light Company.

✦

"Bob" Harper Promoted by Virginia Electric Power

H. Holmes Harper has recently been transferred from the printing and stationery bureau of the Virginia Electric & Power Company at Richmond to the vice-president's office in Norfolk, where he is now assistant to Vice-President R. J. Throckmorton and associate editor of *The Vepcovian*. He replaces A. E. Dunn, who has been transferred to the distribution department at Norfolk.

"Bob" Harper was born near Burkeville, Va., on Nov. 4, 1906. He was graduated from Virginia Polytechnic Institute in June, 1927, with a degree of B.S. in electrical engineering. Mr. Harper joined the Vepco organization as a student engineer and was assigned to the production department at Richmond. He was later transferred to the treasurer's office, where he viewed the various operations of the company from a statistical standpoint, and in June, 1929, he became assistant supervisor in the printing and stationery bureau.

✦

M. M. Lloyd Retires from South Shore

M. M. Lloyd, for more than eleven years superintendent of shops and equipment for the Chicago, South Shore & South Bend Railroad, South Bend, Ind., and its predecessor companies, has retired from active service. His duties have been taken over temporarily by W. J. Freeman.

Mr. Lloyd was born in Rockford, Mich., on April 7, 1868. He went to the South Bend property in 1919 from Saginaw, Mich., where he had been master mechanic of the northwest division of the Michigan Railways. Previously he had worked as master mechanic for the Des Moines City Railway and the Interurban Railway, Des Moines, and the East St. Louis and Alton & Granite City lines in southern Illinois.

His first work was as locomotive engineer and motorman in Wichita, Kan., and then in St. Louis and in Granite City, Ill., as division foreman for the Sprague Electric Company and electrician with the American Steel Foundries.

✦

T. M. van der Stempel Joins General Car & Coach Company

Th. M. van der Stempel, who has been with the McGraw-Hill Publishing Company, Inc., since Jan. 1, 1929, and since April 1 of that year a member of the editorial staff of ELECTRIC RAILWAY JOURNAL, has recently resigned to accept a position with the newly organized General Car & Coach Corporation in Utica, N. Y., in charge of sales.

T. M. van der Stempel

Mr. van der Stempel has spent nearly all his time since his graduation as a mechanical and electrical engineer in 1920 in the transportation engineering field in various capacities. From August, 1924, to June, 1927, he was connected with the Chicago Motor Coach Company. There he learned the intricacies of city bus service from the ground up, starting as conductor and driver and advancing to the position of engineer in the traffic department, a post he relinguished to survey transportation facilities abroad, notably in Central America, South America and in Europe. Thus during 1927 and 1928 he studied the transportation facilities in 23 different countries.

During his work as a member of the editorial staff of ELECTRIC RAILWAY JOURNAL in charge of the new equipment, maintenance and foreign departments, he traveled widely throughout this country and increased his acquaintanceship among operators in both the electric railway and bus fields. His actual operating experience, his extensive study of railway and bus operating practices here and abroad and his work as a journalist all serve to qualify him to fill acceptably his new post in promotional work.

J. K. Bruce Resigns as London Tramway Manager

J. K. Bruce, the general manager of the London County Council's tramways, has tendered his resignation on the ground of ill health. The Council expressed deep regret. Since he became manager in 1924, the tramway undertaking instead of working at a loss as before is now making substantial profits. The change is attributed largely to the policy of Mr. Bruce in meeting competition by providing luxurious seats for tramcar passengers, raising the speed of the cars, improving the lighting, and generally making the service more attractive to the public. Mr. Bruce on retirement on June 30 became entitled to a pension of £805 and a lump sum of £2,426. In view of his great services a special grant of £2,000 is also proposed.

Mr. Bruce entered the service of the Council as a veterinary surgeon in the old horse car days of 1898. He served in turn as deputy chief officer and acting manager before he reached his present position in 1924. Statistics issued by the County Council show how under Mr. Bruce's management deficits on the working of the undertaking were changed into surpluses. Preliminary figures for the financial year ended March 31 show that after paying all expenses and debt charges (sinking fund and interest) there is a net surplus of £52,570. For the financial year now opening the estimate is that there will be a net surplus of £89,000. To recall the magnitude of the London municipal tramway undertaking, it may be mentioned that for the past financial year the receipts amounted to £4,413,450, and the working expenses including renewals to £3,638,505.

✦

Oren Root Resigns from Hudson & Manhattan

Oren Root, for almost eleven years president of the Hudson & Manhattan Railroad, operating under the Hudson River from New York to Newark and to Hoboken, has resigned, effective Sept. 1. The directors have not yet elected a successor.

Mr. Root resigned for personal reasons only. He is only 56 years old, and after a period of rest may re-enter business, but has no definite plans at present.

When Mr. Root took his post, the Hudson & Manhattan first lien and refunding mortgage 5s, Series A, were quoted at 57, and the adjusted mortgage income 5s were 16, while the preferred and common stocks were seldom traded in. An initial semi-annual preferred dividend of 2½ per cent was paid Aug. 15, 1923, and has been maintained to date, while an initial semi-annual common dividend was paid June 1, 1925, at the annual rate of 2½ per cent. The rate was advanced recently to $3.50 annually. The first lien 5s now sell at 99½, the adjusted mortgage 5s at 83⅜, the preferred stock at 81 and the common at 48⅜.

Mr. Root entered electric railway work in 1895 with the Metropolitan Street Railway of New York. He was schooled later in all departments of the company, working as a motorman, conductor, inspector and in other capacities. In 1903, he was appointed general manager of the Metropolitan and on Sept. 20, 1919, was elected president of the Hudson & Manhattan Railroad. He is a nephew of Elihu Root.

Many Changes on New Haven Bus and Suburban Lines

P. W. J. Smith has been made president of the New England Transportation Company, motor coach subsidiary of the New Haven, succeeding A. P. Russell, executive vice-president of the railroad. Mr. Smith, has been general superintendent of the New York, Westchester & Boston Railway and in charge of the motor coach lines of the County Transportation Company for several years. He retired from the New York, Westchester & Boston July 1. He has been connected with the New Haven or its allied lines for 42 years. He will establish headquarters for the New England Transportation Company in Providence, R. I. and will also become president of the County Transportation Company and the Sound View Transportation Company, subsidiaries of the New York, Westchester & Boston.

Leverett S. Miller has been president of the New York, Westchester & Boston Railway since May, 1909, and president of the County Transportation Company since April, 1927. He retired at his own request on July 1, after long and faithful service. For many years, prior to his connection with the New York, Westchester & Boston, he was general manager of the Central New England Railway. The office of president of the New York, Westchester & Boston will be assumed by J. J. Pelley, president of the New Haven.

W. H. Foster, general superintendent, and A. G. Baily, superintendent of the New York division of the New Haven, will act in those capacities with the New York, Westchester & Boston, which are now operated as an integral part of the New Haven rail system.

✦

K. F. Sapp in New Post in Atlanta

Kenneth Finch Sapp, recently appointed assistant to the manager, public relations department, Georgia Power Company, Atlanta, Ga., was born at Ottawa, Ill., on Oct. 11, 1901. He prepared in the elementary and high schools of Ottawa and attended the University of Illinois. Since leaving college, he served as sporting editor of the *Daily Republican-Times*, Ottawa, Ill., and as reporter on the *News-Herald*, Joliet, Ill., and the *Atlanta Constitution*, Atlanta, Ga. He resigned from the *Constitution* in 1925 to become a member of the staff of the public relations department, Georgia Power Company, being appointed editor of publications in November, 1926, and assistant to the manager in May, 1930.

✦

E. C. Rust Eastern Massachusetts Director and Trustee

At a recent meeting of directors of the Eastern Massachusetts Street Railway, Charles W. Hubbard, Jr., resigned and Edgar C. Rust was elected a director in his place. Mr. Rust was also elected a trustee of the road, under the provision of the public control act which permits the road's directors to elect one of the three trustees from among themselves. He fills the vacancy created by the resignation of Lester Watson.

Although he has resigned as a trustee, Mr. Watson will continue to serve as a member and chairman of the board of directors. He is retiring from the board of trustees simply because the duties of membership leave him insufficient time to devote to other necessary affairs. Mr. Watson's firm, Hayden, Stone & Company, still retains the very substantial interest in the road.

Edgar C. Rust, the new trustee and director, is well known in the financial community due to his years of association with E. H. Rollins, from the presidency of which concern he retired last year.

✦

R. M. Heinrichs, Bendix-Westinghouse Manager

R. M. Heinrichs has been appointed general manager of the newly formed Bendix-Westinghouse Automotive Air Brake Company. Mr. Heinrichs comes to the new brake company with a broad experience in the automotive field, having formerly served the Bendix Corporation as assistant to the vice-president in charge of sales. His connection with the Bendix Corporation covers a period of five years, previous to which time he had been identified with the Goodman Manufacturing Company, Chicago. He is a graduate of the engineering school at the University of Illinois.

R. M. Heinrichs

As general manager of the new company, Mr. Heinrichs will have at his disposal the engineering and service departments of both Bendix and Westinghouse effectively to serve the automotive industry. Manufacture of the automotive air brake will continue in the plants of the Westinghouse Air Brake Company at Wilmerding.

✦

Irving M. Tuteur, vice-president of McJunkin Advertising Company, Chicago, was elected president of the Public Utilities Advertising Association for the year 1930-31 at the association's annual convention held recently in conjunction with the annual meeting of the Advertising Federation of America. The new president has served the association for five years as chairman and one year as vice-chairman of its "Better Copy" committee, which has been devoted to the improvement of public utility advertising throughout the country. Under the direction of this committee, four "Better Copy" portfolios of outstanding public utility advertising have been published in the last six years. The committee has also conducted two nationwide "Better Copy" contests among utility companies.

F. L. Butler Heads Commonwealth Transportation Department

Further recognition of his outstanding ability among electric railway operators of the nation was accorded Frank L. Butler, vice-president in charge of railways for the Georgia Power Company, Atlanta, Ga., in his appointment, announced recently, as head of the transportation department of the Commonwealth & Southern Corporation, supervising company for the Georgia Power Company and its associated companies.

In his new position, Mr. Butler will be on call to give advice and assistance to all companies in the Commonwealth & Southern organization on transportation problems, but will remain in Atlanta as active head of the Georgia Power Company's railways. For many years Mr. Butler has been recognized as one of the leading electric railway authorities in America and has been high in the councils of the American Electric Railway Association. He has headed many important committees for that association and has had a leading rôle in shaping its policies. He is at present a member of its executive committee.

✦

J. M. Pogue Elected Vice-President of Interurban

J. M. Pogue, who has been director of purchases and claims of the Cincinnati & Lake Erie Railway at Springfield, Ohio, since its organization early this year, has been elected a vice-president of the concern.

Mr. Pogue will continue to make his headquarters in the interurban building in Springfield, where he has been located for a number of years. He entered the employ of the railway system in 1907, and has served in various capacities under several managements. He acted as general manager for the receiver of the old Indiana, Columbus & Eastern system prior to its absorption by the present company.

The Cincinnati & Lake Erie Railway now is operated under the general supervision of five vice-presidents, one located in Cincinnati, one in Philadelphia, two in Dayton, and Mr. Pogue in Springfield. Its lines extend from Cincinnati to Lake Erie cities and as far east as Columbus.

✦

W. S. Howland Now Edits "Snap Shots"

William S. Howland, editor of *Snap Shots*, Georgia Power Company, Atlanta, was born in New York, on June 18, 1901. He was educated at Phillips Exeter Academy, Exeter, N. H., and Princeton University, being graduated in 1923 from Princeton with a degree of A.B. Since leaving college, he has served as reporter on the *Atlanta Journal* and as a reporter and city editor of the *Tennessean*, Nashville, Tenn. He resigned as city editor of the *Tennessean* in April, 1929, to join the staff of the public relations department, Georgia Power Company, being appointed editor of *Snap Shots* in January of this year. In addition to serving as city editor of the *Tennessean*, he was editor of the *American*, a house organ published by the American Banks, Nashville, Tenn., and was instructor in journalism at George Peabody College for Teachers, Nashville, Tenn., for the summer session of 1928.

H. S. Newton Retires from Utility Work

Henry S. Newton, manager of the Parkersburg-Marietta division of the Monongahela-West Penn Public Service Company for seven years and for the past five years manager of the industrial development department of the West Penn, has retired from utility work. He will take up permanent residence on the eastern shore of Chesapeake Bay, near Easton, Md.

Mr. Newton has been engaged in utility work for more than a quarter of a century. He was graduated from the Ohio State College in electrical engineering with the degree of bachelor of science. His first work was with the General Electric Company, for which he served last as superintendent of one of its plants. After leaving that company he worked in a managerial capacity for various utilities, including the Hartford & Springfield Railway, connecting Hartford, Conn., and Springfield, Mass.; the Syracuse Rapid Transit Company; the Ohio Valley Electric Railway at Huntington, and several railways in Minnesota.

He went with the Monongahela system as manager of its electric railway and power properties at Parkersburg and Marietta and remained in that position for seven years before going to Fairmont, W. Va., as manager of the industrial development department.

OBITUARY

Richard Meriwether

Richard Meriwether, vice-president and general manager of the Dallas Railway & Terminal Company and the Texas Interurban Railway, Dallas, Tex., died on May 26 on a Missouri-Kansas-Texas train at St. Louis, Mo. Mr. Meriwether had left

Richard Meriwether

Dallas for New York on a short business trip. When the train pulled into the St. Louis Union Station a porter attempted to wake Mr. Meriwether, but failing to get any response summoned aid. The doctor who responded said Mr. Meriwether had died from natural causes.

Mr. Meriwether directed one of the few systems of its kind in the country that had maintained steady earnings and a sound financial basis in the face of decreases in the business over the country. He began his management of the company in 1917 and has served continuously.

Born at Frankfort, Ky., Oct. 13, 1875, Mr. Meriwether attended grade and high schools at Louisville, Ky. He entered the Rose Polytechnic Institute, Terre Haute, Ind., where he was graduated with electrical engineering as major subject.

His career began with the Southern Railroad. He then became connected with Siemens-Halske Electric Company of Chicago and the Western Electric Company of Chicago. In 1903 he went with the Louisville Railway as assistant to the superintendent of power, in charge of transmission lines.

Three years later he became associated with the Louisville & Eastern Railroad, an interurban line running from Louisville to Beard Station, Ky. He began as mechanical superintendent and was made general superintendent in charge of operation and construction in 1908.

He accepted a position with Stone & Webster in 1911 and went to Dallas as general superintendent of the Dallas Consolidated Electric Street Railway, the Rapid Transit Railway and the Metropolitan Street Railway. These companies were consolidated in 1917 and Mr. Meriwether became general manager. He was made vice-president and general manager in the spring of 1918.

As managing head of the Texas Interurban Railway, Mr. Meriwether was responsible for the building and operation of interurban lines to Terrell and Denton.

Mr. Meriwether also was active in civic and social affairs of Dallas. He was a director of the Republic National Bank & Trust Company, the Continental & Loan Association and the Better Homes Bureau. He was past-president of the Dallas Rotary Club and the Dallas Athletic Club. He also was a member of the City Club and Brook Hollow Golf Club.

More than 200 employees of the company and other electric railway lines gathered with other friends at the funeral and drove in a mile-long procession to Grove Hill Cemetery, where the remains were interred with Masonic rites.

✦

G. R. Millican

George Raymond Millican, 43 years old, vice-president and general manager of the Evansville & Ohio Valley Railway, died recently at his home in Evansville, Ind.

Besides being vice-president and general manager of the railway, Mr. Millican was president of the board of deacons of the First Presbyterian Church, a member of the Rotary club, a member of the Evansville Country Club, and a member of the Purdue University chapter of the Phi Delta Theta fraternity.

Starting out with the Evansville & Ohio Valley Railway on a surveying gang during vacations from school he remained with that company until death, becoming its vice-president and general manager when barely past 30 years of ago.

He attended Purdue University and in 1907 entered the employ of the railway. In 1910 he was transferred to Owensboro, Ky., as general manager of the Owensboro City Railroad, a subsidiary.

Mr. Millican was born in Evansville on Sept. 19, 1886.

S. R. Artman

Samuel R. Artman, long active in Indiana public affairs and best known for his rulings as a member of the Indiana Public Service Commission, died recently of injuries sustained in a fall from the roof of his home in Lebanon, Ind. Mr. Artman was graduated from the Indiana state normal school at Terre Haute. He taught school for four years and then read law in Lebanon. He was elected to the Legislature and later judge of the Circuit Court at Lebanon. In 1923 he was appointed a member of the Indiana Public Service Commission, remaining in that position six years, when he then was named special assistant attorney general.

✦

H. A. Davis

Hiram A. Davis, who went to Nashville, Tenn., from New Orleans in 1902, to become superintendent of the railway department of the Nashville Railway & Light Company, died on May 30. He served in the one capacity for twenty-eight years.

Mr. Davis was one of the city's active civic workers, and one of the city's most aggressive sponsors of the safety movement. He applied his safety principles to

H. A. Davis

his own street cars, and as a result the company established a record for safety which national authorities declared was unsurpassed. He was an active member of the Nashville Automobile Club, and the founder of the Nashville Safety Council. That his civic work was appreciated is attested by the public recognition it received.

Mr. Davis was born in Oswego, N. Y., on April 3, 1866. He was educated in the New York schools, and entered the electric railway industry as chief engineer at the power station of the Steinway Railway, Long Island City. Shortly afterward Mr. Davis went to New Orleans as superintendent of equipment of the New Orleans & Carrollton Railway, now included in the system of the New Orleans Public Service.

For fifteen years Mr. Davis was a member of the Rotary Club; he was a Scottish Rite Mason and a Shriner; he was an active church worker, being a member of the Board of Deacons of Edgefield Baptist church; he was a member of the board of directors of the Tennessee Children's Home; a member of the board of directors of the Tennessee Hermitage National Bank.

He is survived by his brother, George H. Davis, of the firm of Ford, Bacon & Davis, New York; his wife, Mrs. Isa Outwater Davis, a daughter and a son.

Col. Timothy S. Williams

Col. Timothy S. Williams, former president of the Brooklyn Rapid Transit System, now the Brooklyn-Manhattan Transit Corporation, which he served in various capacities for more than twenty years, collapsed and died suddenly in New York City on June 3 while on a visit to the city made from his estate at Huntington, Long Island.

Colonel Williams succeeded to the presidency in Brooklyn following the retirement of Edwin W. Winter. Mr. Winter had worked like a demon to snatch the system from pending receivership when he took hold and when the work of rehabilitation, which he carried out most expeditiously, was completed he turned the system over to Colonel Williams. Soon after Colonel Williams took charge the new subway contracts were negotiated, but then came the trying experiences due to the World War and in its wake a succession of economic events that the Brooklyn Rapid Transit, as a corporate entity, did not survive. During that period the system, like so many other electric railways, was almost constantly in hot water, politically, economically and financially. Colonel Williams worked prodigiously against the current of events which had set in against the company, but finally came receivership under Lindley M. Garrison and eventually reorganization with W. S. Menden, who had worked side by side with Colonel Williams, as president in complete charge of operation.

Timothy Shaler Williams was born at Ithaca, N. Y., on Aug. 1, 1862. Following his graduation from Cornell University with the class of 1884, he came to New York and joined the staff of the old *Commercial Advertiser*, as a reporter. Later, he served that paper as Albany correspondent, Washington correspondent, city editor and editorial writer. He left newspaper work to become private secretary to Governor David B. Hill, a position he also held with Governor Roswell P. Flower. Upon the retirement of Governor Flower from office, Mr. Williams undertook to reorganize the Long Island Traction Company, out of which grew the Brooklyn Rapid Transit System of companies. In 1895 he became secretary of the reorganization committee. A few months later he was named secretary and treasurer of the Brooklyn Heights Railroad. From 1901 to 1911 he was vice-president of the Brooklyn Rapid Transit System.

✦

R. H. Selbie

R. H. Selbie, general manager of the Metropolitan Railway, London, England, died recently while attending a confirmation service at St. Paul's Cathedral conducted by Bishop Perrin, at which his younger son, Andrew, was one of the candidates. Mr. Selbie was 62 years of age. He had returned on May 6 from a sea voyage of three weeks, taken for the benefit of his health. Mr. Selbie was educated at Manchester Grammar School and Victoria (now Manchester) University. He joined the staff of the Lancashire & Yorkshire Railway before being appointed in 1908 general manager of the Metropolitan Railway. He was also a director of several land and development companies. He served as chairman of the Board of Trade Committee on the utilization and feeding of horses, and was controller of horse transport at the Board of Trade and a member of the Army Forage Committee during the war. For his services he was created C.B.E. Last December he was elected chairman of the General Managers' Conference.

✦

William Gordon Gordon

William Gordon Gordon, manager of the railway and traction engineering department of the Canadian General Electric Company, died in Toronto, May 13, from pneumonia, after a short illness. He was born at Ottawa, July 22, 1877. Mr. Gordon was educated at Winnipeg, Halifax and Cornell University, taking the degree of mechanical engineer and electrical engineer at the latter in 1899. He then entered the General Electric Company's service at Schenectady, N. Y., first in the testing department. While in its railway construction department he had charge of the installation of the first electrically operated train on Manhattan elevated railway, New York. Later he assisted in installing the first multiple-unit equipment for Northwestern Elevated Railway. Subsequently, while in the railway engineering department at Schenectady, he was associated closely with the further development of multiple-unit operation for the New York Central Lines and the Interborough Rapid Transit Company. In 1905 he went to Australia in the General Electric Company's railway interests, and was manager and engineer of North Melbourne Tramways & Lighting Company. He returned to Canada in 1913 and entered the Canadian General Electric Company's service. In 1919 he was appointed manager of the Canadian General Electric Company's railway and traction engineering department.

✦

M. T. Donnelly

Morgan T. Donnelly, assistant counsel to the New York State Transit Commission and former Deputy Public Service Commissioner, died on June 30. He was 47 years old. Mr. Donnelly was appointed to his position with the transit commission on Feb. 6 and soon afterward left on sick leave. He was appointed Third Deputy Public Service Commissioner on Dec. 30, 1919, by former Governor Smith and served two years under Chairmen Lewis Nixon and Alfred M. Barrett.

✦

J. T. Branigan

John T. Branigan, general night superintendent of the Department of Street Railways at Detroit, Mich., died on June 5. Born in County Armagh, Ireland, Mr. Branigan went to Canada with his parents at the age of nine. Thirty-seven years ago he went to Detroit, and in 1899 he became a motorman on the Trumbull Avenue lines of Detroit United Railway, now included in the municipal transportation system. Later he was employed in a similar capacity on the Baker line, and in 1924 he was made assistant superintendent, in which position he remained until 1928, when he was made general night superintendent.

✦

Coker F. Clarkson, lawyer and student of electrical and automobile engineering, who had been secretary and general manager of the Society of Automotive Engineers for twenty years, died on June 4 of heart disease at his home, Sleepy Hollow Farm, Scarborough-on-Hudson. He was 60 years old.

Elmer A. Sperry

Elmer A. Sperry, famous inventor, engineer and manufacturer, died on June 16. He was in his seventieth year. He was a charter member of the American Institute of Electrical Engineers and the American Electrochemical Society and one whose inventions and activities, if not all strictly in the electrical field, all tied in closely with electrophysics. At the time of his death he was chairman of the board of the Sperry Gyroscope Company, Brooklyn.

Elmer Ambrose Sperry was born in Cortland, N. Y., on Oct. 12, 1860. He was educated at the State Normal School, and attended Cornell University, Ithaca, for a short period. A natural-born machinist and inventor, he designed in 1879, while yet a youth, a device for the perfection of one of the first electric arc lamps. This device was generally adopted. In the following year he founded the Sperry Electric Company, Chicago, to manufacture arc lamps, dynamos, motors and other electrical apparatus. This was the first of a long series of enterprises employing electricity promoted by him. They covered such diverse apparatus or fields as beacon lights of many descriptions, mining machinery, electric railway cars, automobiles, airplanes, commercial chemistry, detinning processes and the production of fuse wires.

✦

Edwin W. Winter

Edwin W. Winter, former president of the Northern Pacific Railroad and the Brooklyn Rapid Transit Company, died on June 28 after a brief illness, while on a visit in Fall River, Mass.

Mr. Winter left the post of president of the Chicago Transfer & Clearing Company to take over the presidency and direct the rehabilitation of the Brooklyn Rapid Transit Company in 1903 when relations between the company and the public were strained. It was understood that he was to remain only a short time, but his management was so successful that his service with the company was extended from year to year, and he did not resign until January, 1911. A diminutive man but impressive in appearance, Edwin Winter threw himself into the task in Brooklyn with great zeal, building up quickly one of the most impressive organizations, so far as personnel was concerned, probably ever assembled for a work of the kind, his most able lieutenants including J. F. Calderwood, W. S. Menden, W. G. Gove, A. S. Dutton, Dow Smith, W. O. Wood and others. His work in revamping the system attracted wide attention and received public acclaim.

Mr. Winter had been a railroad man all his life. He was born in Vermont in 1845 and when a youth, entered the service of the Union Pacific Railroad in its construction department. Later he was a contractor's agent in the construction of various railroads and then for three years was claim agent of the Chicago & Northwestern Railroad. He subsequently served with the West Wisconsin Railway as general superintendent and held a similar post with the St. Paul, Minneapolis & Omaha Road, of which he became assistant to the president. In 1897, he was made president of the Northern Pacific, relinquishing that position two years later to become president of the Chicago Transfer & Clearing Company.

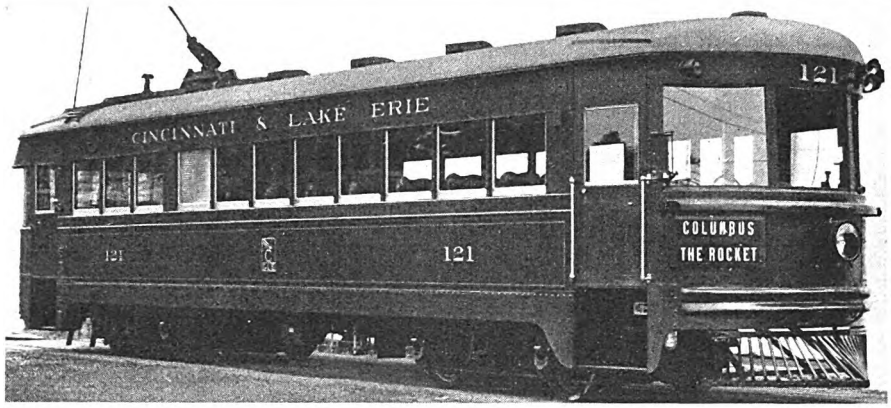
INDUSTRY MARKET AND TRADE NEWS



The new cars of the Cincinnati & Lake Erie Railroad are designed to make a maximum speed of 75 m.p.h.

Cincinnati & Lake Erie Railroad Receives New Cars

Delivery is now under way of the twenty passenger cars ordered last year from the Cincinnati Car Corporation for service on the reorganized Cincinnati & Lake Erie Railroad. Earlier announcements to the effect that these cars would embody many features unusual in design have served to arouse the interest of the industry and their delivery has attracted considerable attention.

Ten of the cars, which are intended for de luxe limited service, contain a lounge compartment at the rear, equipped with comfortable movable furniture, including chairs, sofas, tables and lamps. The compartment is carpeted and is provided with wide-vision windows of plate glass. Incidental equipment includes electric fans, water-operated toilet and lavatory, iced drinking water and other features. The de luxe limited cars have been equipped with Westinghouse motor and control equipment and will weigh complete about 47,700 lb. The other ten cars, which are designed for local service, are provided with General Electric motors, control and brakes. The de luxe cars will seat 38 passengers and the locals 46. Both types are designed for one-man two-men, single-end operation. During initial trials the cars are said to have attained a maximum speed of over 75 m.p.h.

Bodies are of steel construction with extensive use of aluminum. Length over all is given at 43 ft. 9 in., with length over the body posts of 33 ft. 10 in. Width over all is 8 ft. 9⅝ in., with height, rail to trolley base, of 11 ft. 4 in. Truck wheelbase is 6 ft. 2 in., with bolster centers spaced at 23 ft. 2 in. Roof is of the arch type. Other specifications are as shown elsewhere in this issue.

Northwestern Pacific Railroad Orders New Rolling Stock

Seven motor cars and two trailers for passenger service have been ordered by the Northwestern Pacific Railroad, San Francisco, Cal., from the St. Louis Car Company, delivery to be made in September. The railway, a third rail system, is associated with the Southern Pacific lines, and operates from Sausalito, in the Marin peninsula, serving Corte Madera, Fairfax, San Rafael and communities in the Mill Valley region.

The new coaches have an over-all length of 72 ft. 10½ in., and a width over the eaves of 10 ft. 6 in. The motor cars, which are equipped with Westinghouse No. 557 E motors and mounted on trucks supplied by the General Steel Castings Corp., weigh complete 110,000 lb., while the weight of the trail cars is given as 79,200 lb. Body construction is of aluminum and steel, with arch roofs. Seating capacity of the motor cars is 98 passengers and of the trail cars 103 passengers. Additional equipment details are supplied in an accompanying table.

Single-Truck Cars for Louisiana Property

The J. G. Brill Company, Philadelphia, Pa., has recently delivered four single-truck, double-end, one-man motor cars to the municipal street railway of Monroe, La. The cars were built at the plant of the American Car Company, at St. Louis.

Body construction is all steel, with arch roof. Over-all length is 28 ft., over-all width 8 ft., and height, rail to trolley base, is 9 ft. 10⅜ in. Weight is 16,000 lb.

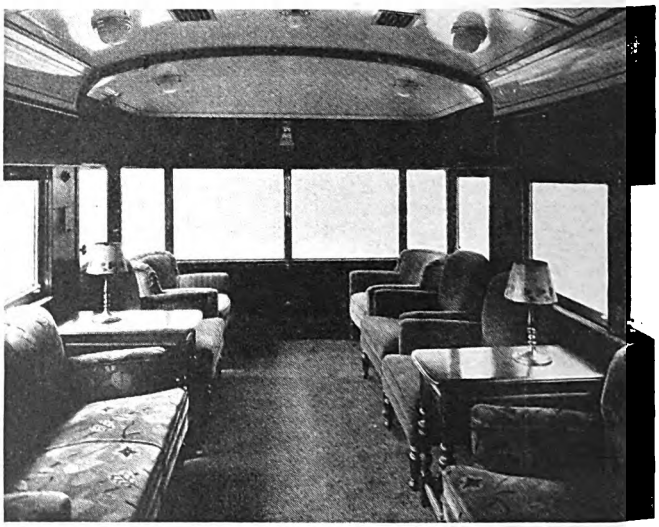
Long Island Railroad Has 85 Steel Passenger Cars on Order

To augment its passenger-carrying equipment this year, the Long Island Railroad recently placed orders for the immediate construction of 45 multiple-unit steel cars at a cost of $1,395,000. Delivery of these cars will begin in August and be completed in September.

The type of car just ordered has a seating capacity of 69 persons and the length over all is 70½ feet. The Pressed Steel Car Company of McKees Rocks, Pa., is building 25 of them, and the American Car & Foundry Company of Berwick, Pa., is constructing the remaining twenty cars.

A special safety feature of the new cars will be a door-interlocking device, or signal light, indicating to the motorman that the doors are closed. Each car will be equipped with train control apparatus. Roller bearing trucks will make riding easier, and better distribu-

Wide aisles, improved lighting effects and leather-upholstered seats add to comfort of travel on new C. & L. E. cars



Individual chairs of rich upholstery, a carpeted floor and wide-vision windows are provided in the observation compartment

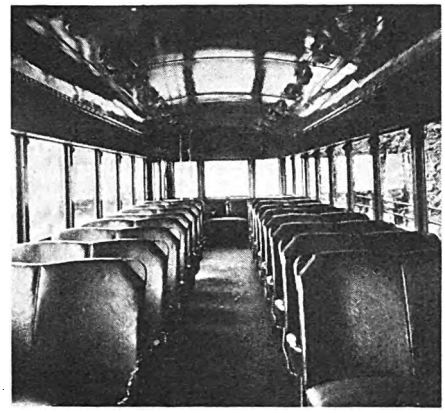
Digitized by Google

tion of lighting will be effected through the installation of additional pedestal lamps in each car and increased wattage of the lamps.

With the 40 multiple-unit cars which were delivered before June 1, the Long Island Railroad will have increased its passenger-carrying equipment in 1930 by 85 cars.

New Des Moines Cars Embody Distinctive Features

Cummings Car & Coach Company, of Chicago, has delivered 40 single-end, all steel, one-man motor cars to the Des Moines Railway for service on its city lines. In appearance the new cars follow a well-balanced design, which is attained by providing wide-vision windows, a narrow letter board and a low arched roof. Exterior painting scheme is carried out in cream above the belt rail and red below, with monogram, numbers and striping in aluminum. The interiors are finished in enamel,



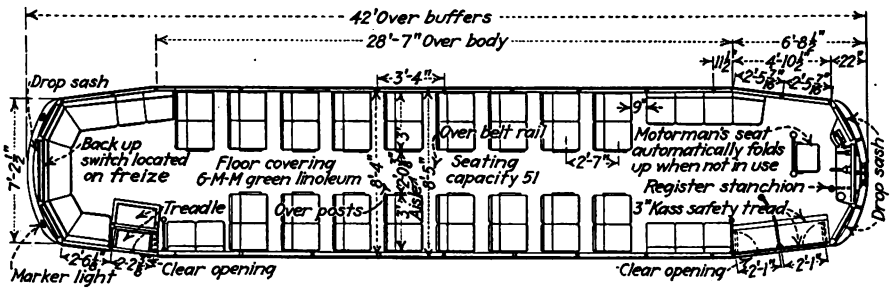
Wide aisles, upholstered seats and ample lighting effects lend a pleasing appearance to new Des Moines cars

with cream headlining. Frieze panel, post capping, sash, window capping and wainscoting are finished in three colors shading from light tan for the frieze panel to dark brown for the wainscoting, the latter matching the brown leather seats.

There are no bulkheads in the car and the headlining is continuous throughout its entire length. Illumination is provided by a large number of dome light fixtures over the center line of the seats on either side. Seats are of semi-bucket type.

Electrical equipment consists of four General Electric No. 247 motors of 40 hp. with tapped fields and K-75 control with safety features. The cars are designed for single-end operation, but are provided with back-up equipment. All doors are pneumatically operated, equipment being provided by National Pneumatic Company. Step wells are provided at front and rear. Entrance and exit doors on front vestibules are selectively controlled, with treadle control at the rear exit. Trucks are Cummings Car & Coach Company's No. 64 equalizer type with 3¼x7-in. journals.

The weight of the cars, completely equipped, is given as 35,300 lb. It is expected to attain an acceleration of 3 m.p.h.p.s., and a free running speed of 37 m.p.h. Additional details are shown elsewhere in this issue.



Des Moines cars provide seats for 51 passengers

The Okonite Company announces the appointment of Elbridge H. McNeill as manager of the power and light department of the company's Chicago branch. Mr. McNeill has had charge of certain railroad, industrial and public utility accounts for the company since 1925. Charles E. Brown, formerly manager of the power and light department of the Okonite Company, has been appointed assistant general manager of the company with headquarters in New York.

Bus Deliveries Continue in Steady Volume

In spite of a continued industrial inactivity in many lines, the purchase and delivery of buses and trolley buses by electric railway properties and their subsidiaries has continued at a steady level, according to advices received from manufacturers. General Motors Truck Company reports deliveries for May as the largest in the company's history, with good prospects that the record would be continued in July and August.

Among the larger deliveries reported by this manufacturer were 127 buses for city service, Type "250," to Public Service Co-ordinated Transport; ten Type U, 21-passenger city service buses to the Reading Transit Company; fourteen Type Z-225 buses to Toronto Transportation Commission; ten Type "250," 33-passenger observation parlor buses to the People's Rapid Transit Company, Philadelphia; four Type Z, 29-passenger city service buses to Washington Railway & Electric Company; one Type Z-38, city service bus to Worcester Consolidated Street Railway; and two Type "250," 33-passenger observation buses to Fort Dodge, Des Moines & Southern Transportation Company. The popularity of the Type U, 21-passenger city type bus is attested by the fact that three were delivered to Pittsburgh Motor Coach Company; two to Sioux Transit Company, Sioux Falls, S. D.; five to Georgia Power Company; two to Virginia Public Service Company, for service in Hampton; two to Central Illinois Transportation Company, Springfield, Ill.; and three to British Columbia Electric Railway.

Mack-International Motor Truck Corporation reports deliveries of four 29-passenger city type models to Durham (N. C.) Public Service Company; three of the same type to Fonda, Johnstown & Gloversville Railroad; one to Holyoke Street Railway; two to Public Service Co-ordinated Transport, and one Model BK intercity type bus to Tacoma Bus Company.

White deliveries include eight Model 65A buses to Virginia Electric & Power Company, for service in Norfolk; nine Model 54 buses to West Penn Electric Company; four Model 54A buses to Boston, Worcester & New York Street Railway, of Framingham, Mass.; seven Model 65A buses to Northern Texas Traction Company, of Fort Worth, and three Model 54 buses to Los Angeles Railway.

Among A.C.F. deliveries were five 40-passenger metropolitan type buses to Boston Elevated Railway; three 23-passenger street car type buses to Illinois Power & Light Company; one 40-passenger metropolitan bus to San Diego Electric Railway, and one 23-passenger electric drive street car type bus to Citizens' Transit Company, Oil City, Pa.

Twin Coach Corporation reports deliveries to Boston Elevated Railway of five urban type buses; seven to Schenectady Rapid Transit Company; two 24-passenger buses to El Paso Electric Company; eight 21-passenger buses for city service to Oakland, for Key System Transit Company, and six trolley buses to the Department of Street Railways, Detroit.

One-Man Double-Deck Buses for Baltimore

Baltimore Motor Coach Company, a subsidiary of the United Railways & Electric Company of that city, is to place twelve double-deck electric-drive buses in service. The units, with seating capacity for 68 passengers, will be operated in the Charles Street service, where a grade of 9 per cent must be negotiated. The twelve gas-electric buses are to replace fourteen mechanical-drive buses at present in service.

Before securing the new buses the company made an investigation of the practicability of operating a double-deck gas-electric bus with one man. After tests with a sample equipment and analysis of operating conditions in Baltimore and other cities, it was concluded that such operation was practicable.

Pacific Electric Completes Repair Layout at Long Beach

Representing an investment of $270,000, complete new quarters for the housing, repair and supplying of power to its Long Beach division have been completed by the Pacific Electric Railway. The new facilities replace structures more centrally located, which, due to the phenomenal growth in population of Long Beach, had become too valuable for the purposes used. The new layout is designed to meet not only present but future needs.

The principal structure in the group is a carhouse, which is 77x222 ft. It is substantially constructed with steel frame, corrugated transite siding and roof, steel sash and concrete floor. There are 6,621 lineal feet of trackage and 29,420 sq.ft. of oil macadam paving to serve the various structures. Facilities within the carhouse consist of locker rooms and toilets, shop, store and line department offices and the repair shop. Four car pits are provided, as well as track capacity for the storage of fourteen cars.

In addition to the necessary repair and maintenance equipment, the bus garage, which is 65x77 ft. in size, provides store room, office, locker room and oil room. Storage capacity is also provided for 6,000 gallons of gasoline. The substation unit, which is of fireproof construction, has a capacity of 1,600 kw., supplied by two motor-generator sets, one of 600-kw. and the other of 1,000-kw. capacity. Other structures include a lineman's three-car garage, a four-car concrete wash rack of special design, and a sand house.

Ample fire protection for all units has been provided by placing fire hydrants at suitable locations throughout the buildings and yard. The entire layout was designed and constructed under the direction of the company's engineering department.

New Cars Received by Canadian Property

Three double-truck, double-end motor cars for interurban service on the Windsor, Essex & Lake Shore Railroad, a division of the Hydro-Electric Power Commission of Ontario, were delivered during July by the Ottawa Car Manufacturing Company. The cars, which will seat 50 passengers, are of all steel construction, with arch roofs. Length over all is 51 ft. 2 in., with length over the body posts of 37 ft. 10 in. Over-all width is given as 8 ft. 3 in. Four Westinghouse No. 548 motors are provided, with Westinghouse H.L. control. Weight of the completed unit is given as 63,000 lb. The order also includes a trail car of the same general dimensions.

Additional equipment specifications are listed elsewhere in this issue.

Electric Railway Material Prices—July 5, 1930

Metals—New York

Copper, electrolytic, delivered, cents per lb.	12.00
Lead, cents per lb.	5.25
Nickel, cents per lb., ingot	35.00
Zinc, cents per lb.	4.50
Tin, Straits, cents per lb.	30.25
Aluminum, 98 to 99 per cent, cents per lb.	23.30
Babbitt metal, warehouse, cents per lb.:	
Commercial grade	41.00
General service	31.00

Bituminous Coal

Smokeless mine run, f.o.b. vessel, Hampton Roads, gross tons	$3.90
Somerset mine run, f.o.b. mines, net ton	1.75
Pittsburgh mine run, Pittsburgh, net ton	1.40
Franklin, Ill., screenings, f.o.b. mines	1.60
Central, Ill., screenings, f.o.b. mines	1.25
Kansas screenings, Kansas City	1.85

Track Materials—Pittsburgh

Standard steel rails, gross ton	$43.00
Railroad spikes, drive ⅝ in. and larger, cents per lb.	2.80
Tie plates (flat type), cents per lb.	2.08
Angles bars, cents per lb.	2.75
Rail bolts and nuts, cents per lb.	3.90
Steel bars, cents per lb.	1.80
Ties, white oak, Chicago, 6 in. x 8 in. x 8 ft.	$1.40

Hardware—Pittsburgh

Wire nails, base per keg	$2.20
Sheet iron (24 gage), cents per lb.	2.55
Sheet iron, galvanized (24 gage), cents per lb.	3.20
Galvanized barbed wire, cents per lb.	2.85
Galvanized wire, ordinary, cents per lb.	2.80

Waste—New York

Waste, wool, cents per lb.	10.00 to 15.00
Waste, cotton (100 lb. bale), cents per lb.:	
White	9.00 to 12.00
Colored	6.00 to 10.00

Paints, Putty and Glass—New York

Linseed oil (5 bbl. lots), cents per lb.	14.2
White lead in oil (100 lb. keg), cents per lb.	13.75
Turpentine (bbl. lots), per gal.	0.54
Putty, 100 lb. tins, cents per lb.	5.725

Wire—New York

Copper wire, cents per lb.	13.75
Rubber-covered wire, No. 14, per 1,000 ft.	$5.05
Weatherproof wire base, cents per lb.	14.00

Paving Materials

Paving stone, granite, 5 in., f.o.b.:	
New York—Grade 1, per thousand	$150.00
Wood block paving 3½, 16 lb. treatment, N. Y., per sq.yd., f.o.b.	2.70
Paving brick 3½x8½x4, N. Y., per 1,000 in carload lots, f.o.b.	50.00
Paving brick 3x8½x4, N. Y., per 1,000 in carload lots, f.o.b.	45.00
Crushed stone, ¾-in., carload lots, N. Y., per cu.yd., delivered	3.40
Cement, Chicago, in carload lots, without bags, f.o.b.	1.95
Gravel, ¾-in., cu.yd., delivered New York	3.40
Sand, cu.yd., delivered New York	2.15

Old Metals—New York and Chicago

Heavy copper, cents per lb.	9.25
Light copper, cents per lb.	8.00
Heavy yellow brass, cents per lb.	5.50
Zinc, old scrap, cents per lb.	2.00
Lead, cents per lb. (heavy)	3.75
Steel car axles, Chicago, net ton	$15.25
Cast iron car wheels, Chicago, gross ton	13.75
Rails (short), Chicago, gross ton	14.00
Rails (relaying), Chicago, gross ton (65 lb. and heavier)	28.50
Machine turnings, Chicago, gross ton	6.50

Chicago Transit Settlement a Message to the Industry

CHICAGO'S display of good sense in passing the franchise ordinance providing for co-ordination of transit facilities was more than a victory for the companies involved. Important as it was to the city and the local railways, the adoption of the ordinance really was a victory for the entire industry in that it recognizes more effectively than do other modern grants, the right of the companies to live and the community of interest that exists between them and the municipality.

There is a far-reaching civic aspect to settlements of this kind, and Chicago took that aspect properly into consideration. The rapid transit lines, with a 50-year renewable franchise granted under the steam railroad law, were in a good position. On the other hand, the grant of 1907 under which the Surface Lines was operating was limited to a term of twenty years in accordance with state corporation law. For nearly this entire period it has been difficult to obtain money for development of the property to meet the city's growth. In the face of the expiring franchise and the uncertainties that necessarily are a part of negotiations for a new grant, however, the Surface Lines never let down. By this attitude the railway built up public good will which was an influential factor in the favorable outcome of the recent referendum.

In the new deal, recognition has been secured of the right of the companies to live. The principles have been established that they are entitled to rates that are self-sustaining, that subways shall be built with city money and by the assessment method, that the terminable permit is a sound device, that valuation is more than a matter of barter and trade and should be carried forward on a basis of fact, and that any excess earnings over an amount needed by the companies to carry on aggressively day by day shall go to the general improvement of the system at once. These are matters of great significance as reflecting changed points of view—points of view that augur well for Chicago in the future.

In addition, the new grant is significant in that it recognizes the fact that a comprehensive program of rapid transit development should be the backbone for the future, while it takes full account of the need for the intensive use of the street car, the bus and the trolley bus, in their respective fields. In the future the character of the traffic carried on the surface lines is likely to change greatly. As they lose in through riders, they will become increasingly important as feeders. Now only 20 to 30 per cent of the total of passengers carried in Chicago are transported on the rapid transit lines. Under unification these proportions may be expected to change, but only to the extent that scientific planning shall determine.

Already a start has been made on the program of improvements—a start that calls for the immediate expenditure of $12,000,000 even before formal acceptance of the grant has been filed on behalf of the new consolidated company. Articulation and rapid transit planning are going ahead. The more pretentious parts of the $200,000,000 program calling for rapid transit construction must necessarily proceed slowly toward realization, but co-ordination of existing facilities and the building of supplementary surface tracks and the installation of bus and trolley bus lines will go forward at once and as fast as is consistent with careful planning.

Politics Should Not Be Permitted to Seep Into Utility Regulation

DISQUIETING proposals have appeared of late indicating politics is likely to play a larger part in utility regulation in the future than it has in the immediate past. Not long ago the governor of New York spoke of the need for "a strong-arm man who will bring the [Public Service] commission back to its original role of defender of the public interest." During recent sessions of the legislatures of various states, a number of ill-considered and impracticable measures, aimed at the utilities, were introduced. The cry has been raised that it would be better for the state to own the utilities than for the utilities to own the state. While the electric railways were not, in most instances, the primary targets of the law makers, the industry cannot afford to stand aloof on the side lines and watch.

Utility regulation has evolved painstakingly. Many utility heads have accepted the idea reluctantly, but the majority have realized its advantages. They were for it in the beginning and they are for it now. Those who have done things in contravention of the regulatory law, however, have been sufficient in number to give political promise to the cry that regulation has broken down. By its very nature regulation, born as the result of popular hue and cry against the utilities, has always been susceptible to the charge of manipulation. The original idea was to take the utilities out of politics by means of regulation. In this a considerable measure of success was achieved. But of late it has been apparent that politics is playing an ever increasing part in regulation. Therein lies a serious menace to the future of the utilities.

High-minded men in the industry sense the growing menace. Supine acceptance of regulation by the utilities is one thing: unyielding opposition to the exercise of the right of the state to have a hand in the control of its own creatures, is something quite different. The question is not merely whether certain practices are legal, but whether under present economic and social conditions, they are in the public interest. The situation is

Digitized by Google

fraught with grave dangers. The utilities can meet it most successfully by keeping the public informed on fundamental principles of valuation, rate-making and similar subjects which are the chief concern of regulation. The idea of regulation is sound. The menace to regulation lies in its possible political perversion. Any serious threat at the commissions imperils the railways.

Merit Alone Should Control Substitution of Buses for Cars

THAT something should be done to improve surface transportation facilities in New York City has long been apparent. Recently attention has been focused anew on this important subject by the proposal of the New York Railways to substitute buses in place of cars on all of its lines. As the interests which now control this company have always been staunch advocates of the bus as a mass transportation vehicle, it is not surprising that they should suggest buses as the solution of the problem. Moreover, there has been considerable public and political agitation for the creation of an extensive system of bus routes in Manhattan. The establishment of such a bus system upon a competitive basis would almost certainly have a ruinous effect upon existing street railway lines. Substitution of buses for cars on the routes of the New York Railways might, however, forestall the establishment of an independent bus system.

That the proposed wholesale substitution is actually the best solution of the surface transportation problem seems doubtful. Conditions are not the same on all of the routes of this company, and the type of vehicle which is best suited for one is likely to be unsuitable for another. The particular needs of each route should be studied. Where the bus is a better vehicle than the street car to meet these needs, the substitution should be made. Where the street car is a better vehicle, it should be retained.

Exaggerated ideas of what can be accomplished by bus substitution are prevalent. While the bus is an excellent vehicle for certain purposes, those who expect to find in it a miraculous cure for all of New York's transportation troubles are doomed to disappointment. Many of the advantages which the bus possesses under favorable circumstances would be lost under the conditions existing in mid-town Manhattan.

For example, one of the ordinary advantages of the bus is its ability to draw up to the curb to receive and discharge passengers. In New York, however, the advantage actually gained through this flexibility is comparatively small. With almost universal parking, the curb is inaccessible. Even where there is no parking, buses seldom pull in closer than 5 or 6 ft. from the curb. No doubt it is easier for a prospective passenger to wait on the sidewalk and step out this short distance to board a bus than it is for him to wait unprotected in the center of the roadway for a street car. But there is no reason why he need wait without protection. The safety isles used in scores of other cities provide waiting places as safe as the sidewalks. They could be used equally well in New York.

Speed is often cited as an advantage of the bus, but this advantage could not be realized on New York's congested streets, where all vehicles have been forced to crawl because of the system of traffic control. At present the car speed on the New York Railways averages 6 m.p.h., while the average speed of the Fifth Avenue Coach Company's buses is a little more than 7 m.p.h. The latter, however, includes considerable operating outside the congested area. In Chicago, where modern traffic signals are used and all parking is prohibited in the business district, the average speed of street cars is 11.44 m.p.h., and even in the most congested section, the Loop, it is between 6 and 7 m.p.h. From this it would appear that speed depends on traffic conditions rather than on the type of vehicle.

A widespread belief prevails that general substitution of buses for cars would contribute to the relief of traffic congestion. In reality, the result would probably be to make congestion worse on heavily traveled routes, as more vehicles would be required to handle the same number of passengers and these vehicles would be weaving in and out across several lanes of traffic, instead of moving in a straight line in the center of the street.

On heavy traffic lines the bus possesses no advantage over the modern car from the standpoint of operating cost. Because of the age and worn-out condition of its equipment, the present operating cost of the New York Railways is extremely high, being in excess of 53 cents per car-mile, while revenue is 66 cents per car-mile. Buses certainly could be operated for considerably less than 53 cents per mile. In fact, the costs of the Fifth Avenue Coach Company are now about 45 cents per mile. If buses were substituted in place of cars, however, a considerable increase in the number of vehicle-miles would be required to accommodate the heavy traffic, and the receipts per bus-mile would be materially less than present car-mile receipts. On the other hand, experience in other cities shows that modern street cars can be operated for less than 40 cents per mile, and their use in New York would permit a reduction from the number of car-miles now operated with a corresponding gain in car-mile receipts.

In view of these facts it appears that complete substitution of buses for cars on all the lines of the New York Railways would be a mistake. While improvement in surface transportation facilities is urgently needed, it would be well to proceed with sufficient deliberation to assure the selection on each route of the type of vehicle which is best suited to meet its particular transportation needs.

City Transit Problems Are Becoming Better Understood

TRAFFIC engineers, city planners and operating officials of public transit facilities have long recognized that the street car, the bus and the taxicab have definite places in the general scheme of urban transportation. Transportation to be successful must be profitable. Uncontrolled and unregulated competition has always proved detrimental to profits. Not only do the operating companies suffer, but the service rendered to the public also suffers.

That these simple facts are becoming more widely understood is encouraging. Publications other than those of the technical press are discussing traffic and transportation problems more frequently. Editors are presenting to their readers the basic problems of city transit and are appealing for support in their solution.

In a recent issue of the *Saturday Evening Post* the leading editorial discussed the subject of co-ordinated transportation and particularly the evils resulting from cut-rate or low-rate taxicabs. It was pointed out that

Digitized by Google

in the great majority of places the street car easily carries the bulk of the load, and that no substitute can take its place because of the inherent lack of street room. "Buses, taxicabs and private automobiles are all important and desirable," continued the editorial, "but they are less essential than the street car or subway, where there is one, and city transit cannot reach its proper goal until this fact is taken more fully into consideration by city planners and traffic experts."

Appealing for regulated co-ordination the editorial continued: "Just as the street railway deserves a living wage, so does the taxicab. Just as one is a proper subject for strict regulation by a utilities commisison, so is the other. It is difficult to see how conditions can be anything but chaotic unless the number of taxicabs are regulated and unless reasonable fares, both maximum and minimum, are provided by public utility."

Views such as these, based on sound reasoning, presented in an unbiased manner to the millions of readers of the *Saturday Evening Post* undoubtedly will have a far-reaching effect.

Few Pension Plans on a Sound Basis

PENSION plans for veteran electric railway employees appear to be approaching a critical period in their development. In one recent instance, it was necessary to revise pension rates downward because the expense threatened to become too heavy for the company to carry. On another subway system, additions to the pension roll have been temporarily suspended for a similar reason. Confidential replies received to an inquiry recently made by the JOURNAL indicate that a considerable number of electric railway managers are apprehensive concerning the future status of their pension plans. Evidently it is time for the industry to pause and consider the situation carefully.

Apparently the difficulty arises because a majority of the present pension plans were not originally established on a sound actuarial basis. The payment of benefits is now found to be exceeding the early estimates. In part, this is due to the increase which has occurred with the passage of time in the number of eligible employees. In part, it is due to the present high wages upon which the pensions are calculated, which were not foreseen when the plans were first established. There is a cumulative effect which must be viewed at long range to be fully appreciated, and few railways appear to have realized at the beginning what the ultimate results would be.

With the exception of a small number of railways which have established reserve funds, it is the practice to make current pension payments out of current earnings. In this the electric railways are following the practice imposed upon the steam railroads by the Interstate Commerce Commission. It is inevitable, however, that with obligations increasing steadily, difficulties will be encountered in making pension payments by this method. No company should agree to make a future obligation without at the same time making some provision for funds from which to pay it.

Despite the difficulties which are being encountered, the railway executives replying to the JOURNAL's inquiry were unanimous in expressing the belief that the railways should provide pensions for veteran employees. This is not a matter of charity, but of sound business practice. To be successful, however, pension plans must be based upon something more than good intentions and guesswork.

Increasing Speed Through Detailed Analysis

SPEED is one of the most vital factors in modern surface car transportation. Passengers are interested in comfort, convenience and attractive appearance of cars, but they are even more interested in speed. If one of the original electric cars of 40 years ago could, by some magic, be made to travel at 40 miles an hour, it would undoubtedly be able to take away business from the more comfortable and attractive electric car of today, operated at present speeds. Only in so far as its speed enables it to hold its place in traffic, can the electric railway car hold its place in the transportation scheme.

All this is well understood by electric railway men. Merely to say that speed is essential, however, accomplishes little. The vital question is how to increase present speeds. So many difficulties lie in the way of achieving this objective that operating officials frequently become discouraged. Perhaps one reason for this is that the problem is usually looked at in its entirety. Viewed in that way, the difficulties appear exceedingly formidable. But if the problem is broken down into component parts and each part considered by itself, the obstacles no longer seem insurmountable.

The first step in this direction might well be to make a detailed analysis to determine accurately the actual speed on short sections of each route. Preferably, the limits of these sections should not correspond with old established time points, but should be points arbitrarily selected at approximately equal distances along the line. Such an analysis will show a wide variation between the speed on some sections and the speed on others, and it is quite likely that loss of time will be disclosed at unexpected places. By attacking these problems one by one, a number of small improvements can be made which, in the aggregate, will produce a substantial reduction in the over-all running time.

Many of the contributory causes of slow operating speeds are within the control of the railway. Frequently it will be found that the acceleration and braking rates are too low. Perhaps the cars have not sufficient power to negotiate the grades. It may be that the entrance and exit arrangements prevent quick loading and unloading of passengers. Sometimes it is wrongly supposed that safety demands slow speeds. Or it may be that time is lost because of long established operating customs that could easily be changed. Looking at the problem as a whole, it is often difficult to discern the true reason for slow operation. Looking at it in detail, the reasons soon become evident.

The method of detailed analysis is valuable also in studying conditions outside the immediate control of the railway. A widespread tendency exists to blame traffic congestion for most of the delays which occur in street car operation. Certainly there is considerable justification for this attitude. But the municipal authorities are probably doing the best they know how to speed up traffic movement. Specific suggestions are of infinitely more value than a general indictment of existing conditions. If a particularly bad situation is pointed out to them and a means of improving the railway service suggested, the municipal authorities will usually be entirely willing to co-operate in effective improvement.

No magic solution of the problem is likely ever to be found. But the first step in effecting improvement is exact knowledge of what the trouble is, and where it occurs. Only by detailed analysis can these questions be answered.

Chicago to Have

Immense Transportation

RATIFICATION, on July 1, by a vote of 325,837 to 56,690—nearly six to one—of the new Chicago transportation ordinance marked the completion of the efforts of the city authorities, public bodies and the companies involved, to arrive at a plan to give the city of Chicago and the entire metropolitan area a unified local transportation system. The campaign has been prolonged many years and has gone through vicissitudes of various sorts, but out of it has been evolved a plan which should give Chicago a type of local transportation second to none in the world.

The ordinance, which was passed by the City Council on May 19 by the affirmative vote of 47 of the 50 aldermen, calls for a comprehensive unified local transportation system for Chicago and the metropolitan area. It is based on principles which long have been agreed to by leaders of thought on the subject. Elevated lines, subways, surface cars and buses are included in the plan. In addition to the consolidation of systems, a city-wide program for extensions, additions and improvements to the transit system is mapped out in the ordinance. The new company which is now being formed, to be known as the Chicago Local Transportation Company, will be required to expend at least $200,000,000 during the first ten years of the grant, in the construction of extensions and additions which are specifically described in the ordinance. Of this sum, $65,000,000 must be expended during the first three years of the grant. Thus the project provides not only for a system adequate for the immediate needs of the city but capable of expansion to meet future demands. Further extensions, additions and improvements may be required by order of the Transit Commission upon the authorization or direction of the City Council. Many more extensions and additions may be required during the first ten-year period as well as thereafter.

Twice before ordinances for unification of the transit facilities in Chicago have been prepared and adopted by the City Council. But both were defeated at the polls. In addition, numerous plans have been worked out in more or less detail which have been discarded before being brought to a vote. It is needless to recapitulate here the various projects that in the past have been suggested for solution of the transportation problem. They have been discussed in detail in this paper from time to time.

The ordinance, in its final form, represents the united efforts of the City Council's committee on local transpor-

Digitized by Google

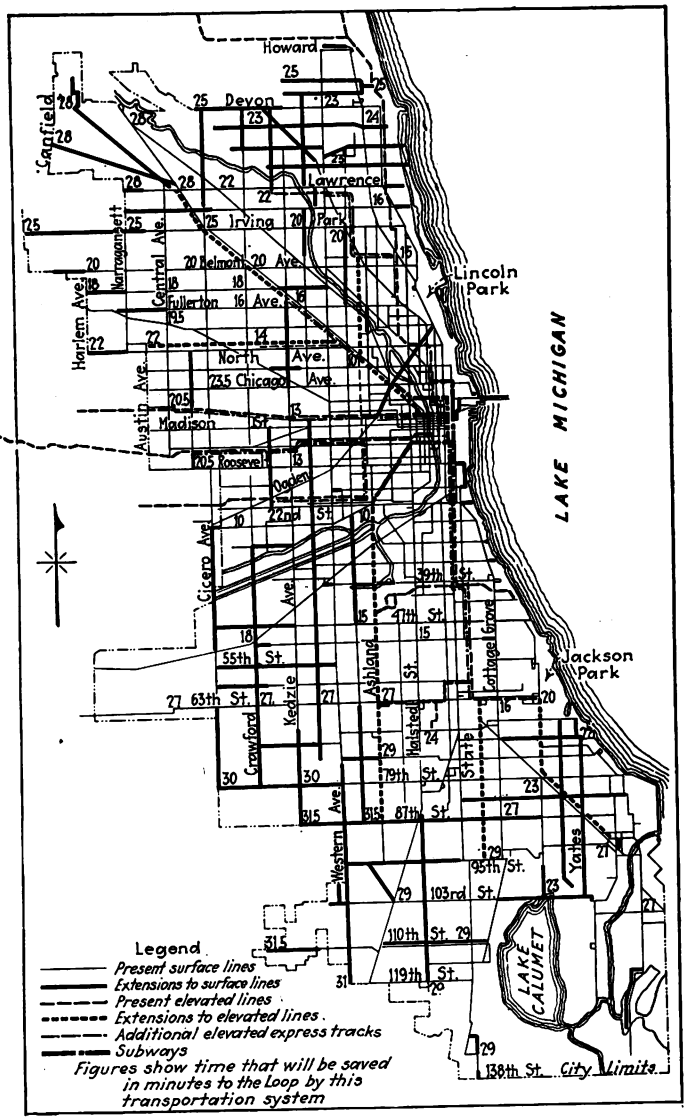
tation, of which Joseph B. McDonough, alderman of the Thirteenth Ward, is chairman, and its sub-committee, aided by the Citizens' Traction Settlement Committee and various civic organizations. The work on this draft of an ordinance dates back to June, 1928, and its provisions are based on legislation obtained at the last session of the Illinois General Assembly. This legislation was necessary to remove certain bars which stood in the way of the consolidation. One of these was that the elevated lines were organized under the steam railroad law, while the surface lines were organized under the street railway law. Another was the removal of the definite twenty-year term from the franchise, which was the maximum permitted in the state.

Home Rule a Feature

Provision is made in the ordinance for a comprehensive unified local transportation system, operated under a terminable permit by one corporate management, and subject to control of a local home rule commission of three members to be appointed by the Mayor. In addition to the

Ratification by voters of ordinance for unified transit assures construction in ten years costing $200,000,000. This includes rapid transit, surface cars and buses. In addition the city will construct subways costing $100,000,000. Details of the ordinance are given

Development



This map of the Chicago transportation system indicates how the $300,000,000 will be spent within the next ten years

The extensions include 300 miles of surface lines and 110 miles of single track for the rapid transit system. This will amount to an increase of 30 per cent in the surface lines system and 56 per cent in the rapid transit system. Subways are included for the central business district, but they will be constructed by the city at its expense. The plans also include the purchase of 1,000 rapid transit cars and 1,000 surface cars or buses.

expenditure of $200,000,000 by the company within the ten-year period, the city is to build a subway system in which it will invest the sum of $100,000,000 and for which the company will provide equipment and operate cars as a part of the rapid transit system, the cost of the subways to be met by use of the city transit trust fund and such special assessments as can be levied upon the property especially benefited.

The initial rates of fare provided in the ordinance are to be unchanged from those at present existing on the rapid transit and surface lines. There is, however, a provision that transfers will be issued between the two systems. Free transfers will be given from the rapid transit lines to the surface lines, and transfers will be given from the surface lines to the rapid transit lines on payment of 3 cents. Universal transfers on all of the surface lines and on all the elevated lines are to be maintained, providing for a continuous ride in one general direction over the entire system.

Under the new ordinance the company is to pay, as compensation for the use of public property, 3 per cent of its gross receipts, plus any excess in any fiscal year over a just and reasonable return as fixed from time to time by the local transit commission. The gross receipts of the existing traction companies for the year 1929 were $83,985,242, of which 3 per cent would amount to $2,519,557. This is slightly less than 55 per cent of the net receipts for the year, which is the amount that would be paid under the present arrangement with the surface lines, plus the small amount received from the elevated lines. This 3 per cent, however, will increase in amount with the growth of population and traffic and with any increase in the rate of fare, while the net receipts may be substantially reduced by increased operating expenses, such as the employee pension fund.

The present traction fund of $61,250,620 is to be turned over to the city transit fund or utilized in such other manner as the city may provide for the construction of the initial subways. Following this construction the city may, if it wishes, apply the fund to future subways or subway extensions and to certain relatively minor purposes specified in the ordinance. The primary purpose

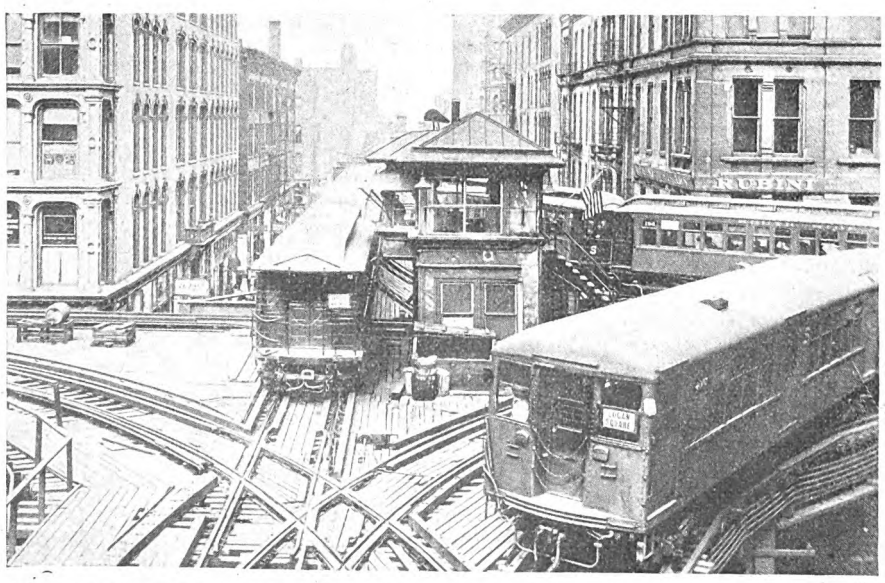
Digitized by Google

One of the latest cars of the Chicago Surface Lines, recently put in service

of this fund, however, is the amortization of the capital value of the company and the corresponding reduction in the purchase price at which the city or its permittee may take over the property, and also the corresponding reduction of the investment upon which the just and reasonable return to the company is based under the law as now declared by the state and federal courts.

The city is to have the right to purchase the traction properties at any time upon payment of the company's then unamortized capital value, and may designate a permittee which shall also have the right of purchase, subject to the provision that the permittee shall pay an additional percentage of the capital value if the purchase is made during the first twenty years. The ordinance also contains specific provisions for amortization applicable to special conditions such as the removal of the elevated loop, the sale of real estate or other property, the application of insurance money now used to replace the property insured, and the application of the renewal fund for amortization when property is retired or abandoned and not replaced.

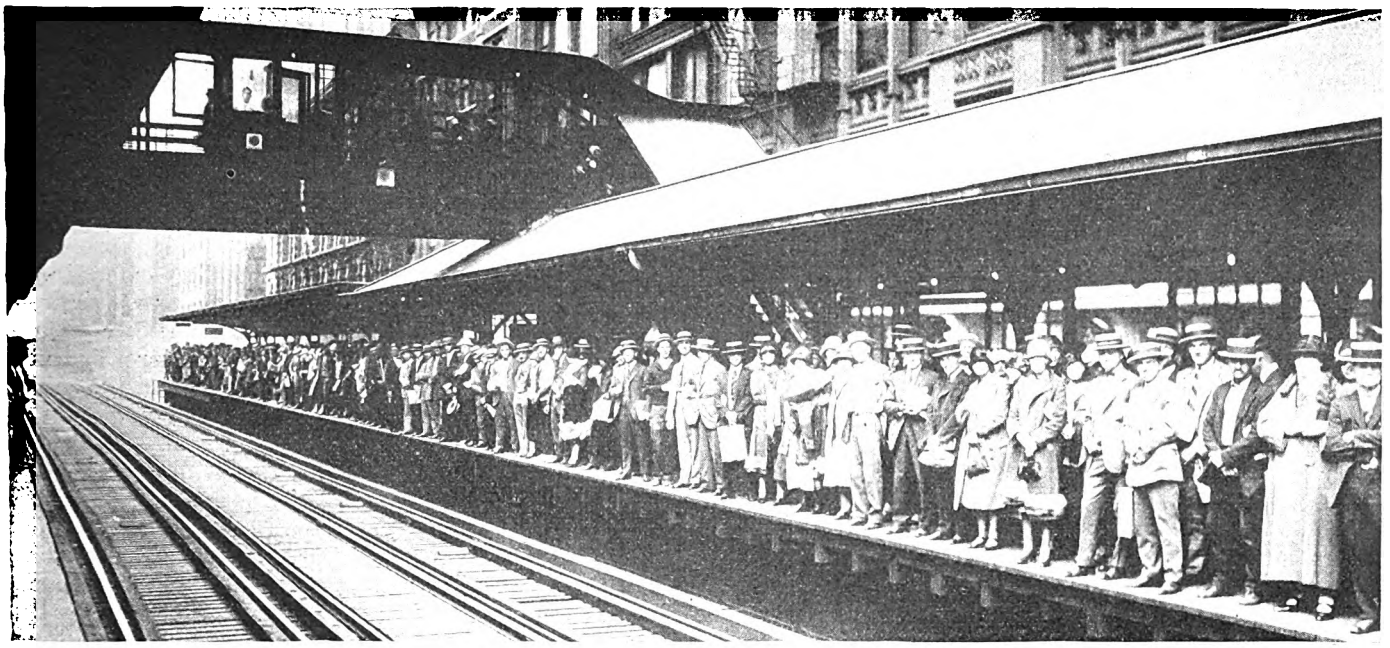
Before the new company can accept the ordinance it must acquire all the properties and rights of the existing street and elevated railroads. The total or aggregate value of these properties is agreed to be, as of Aug. 31, 1929, the sum of $260,442,063, with appropriate adjustment of this value by actual capital additions and deductions to the date of actual acquisition. The company is given the right to purchase these properties subject to certain existing mortgages or liens of the rapid transit company. The reason for this is that there is no effective method by which the Chicago Rapid Transit Company can remove these mortgages or liens except at an unjustifiable cost to the company. They will, therefore, be allowed to run until maturity, when they will be replaced by other securities of the new company subject to the provisions of the ordinance.



This intersection at Lake and Wells Streets, the northwest corner of the Loop, is said to be the busiest railroad crossing in the world. In the maximum hour, 224 trains of 1,244 cars pass through it

The valuation of $260,442,063 was arrived at by adding to the purchase price or capital value of the properties of the surface lines under the provisions of the ordinance of 1907, the present value of the rapid transit system as appraised at the request of the City Council's committee on local transportation. This appraisal was confined to the physical properties; nothing was included for franchise rights or other intangibles. Leading authorities agree that this valuation is fair and is fully in

Digitized by Google



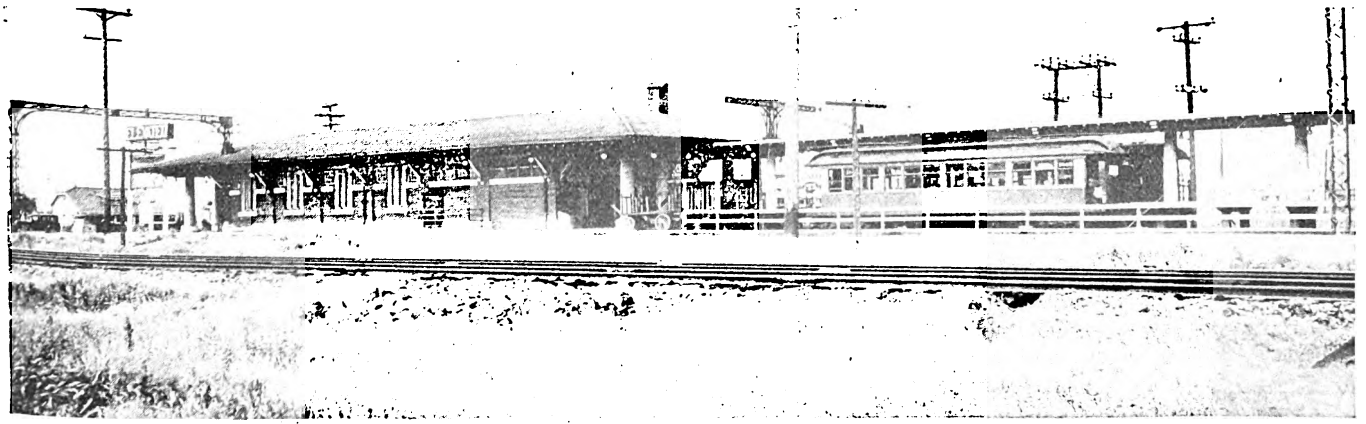
A daily scene in the rush hour. One of the platforms of the Adams and Wabash Station of the Elevated. Here both tracks run northward

accord with the earlier legislation. To this initial capital value is to be added in the future only the actual expenditures in money for additions to plant and property, as approved from time to time by the transit commission, together with such amounts as the company may supply with the approval of the commission for working capital. In the event of purchase by the city or its permittee, the working capital as well as the properties constituting the system will be required by the purchaser.

Necessity for rapid transit improvements is recognized in the ordinance, and a certain amount of central subway construction is specifically provided. There is to be a four-track north-and-south subway on State Street from a junction with the present elevated lines at Chicago Avenue to a junction with the present elevated lines near Sixteenth Street. This will immediately relieve the elevated loop and enable it to be utilized for rapid transit facilities primarily serving the west side. An additional subway primarily serving the west side, which includes northwest and southwest, is to be constructed by the city within the ten-year initial construction period. For transfer from one subway to another and between the elevated structures and subways conveniently and without either transfer slips or additional fare, six pedestrian tunnels or passageways are to be constructed. These subways are imperatively needed to accommodate the traveling public which desires to pass to or through the central business district. In addition, elevated lines will be provided, such as the mid-city line, so that those who wish to travel between outlying points can do so quickly and conveniently without passing through the central business district.

Special assessments against benefited properties are recognized in the new ordinance. It provides that the city shall proceed to construct or acquire such subways out of new funds raised by such special assessments as the city may deem necessary and proper, or out of the city transit trust fund, or both. The ordinance states specifically that there is no obligation on the city to raise funds for financing subways by general taxation.

Among the rapid transit extensions listed in Exhibit B, the principal ones are a mid-town trunk line extending along or near Ashland Avenue from 87th Street to the Douglas Park branch; an extension on Milwaukee Avenue to Lawrence Avenue; an extension of the Humboldt Park branch from the present terminus along West North Avenue to Austin Avenue; an extension along Milwaukee Avenue to connect with the



Rapid transit service already has been extended well into the suburbs. This is the Dempster Street terminal of the Niles Center branch

Digitized by Google

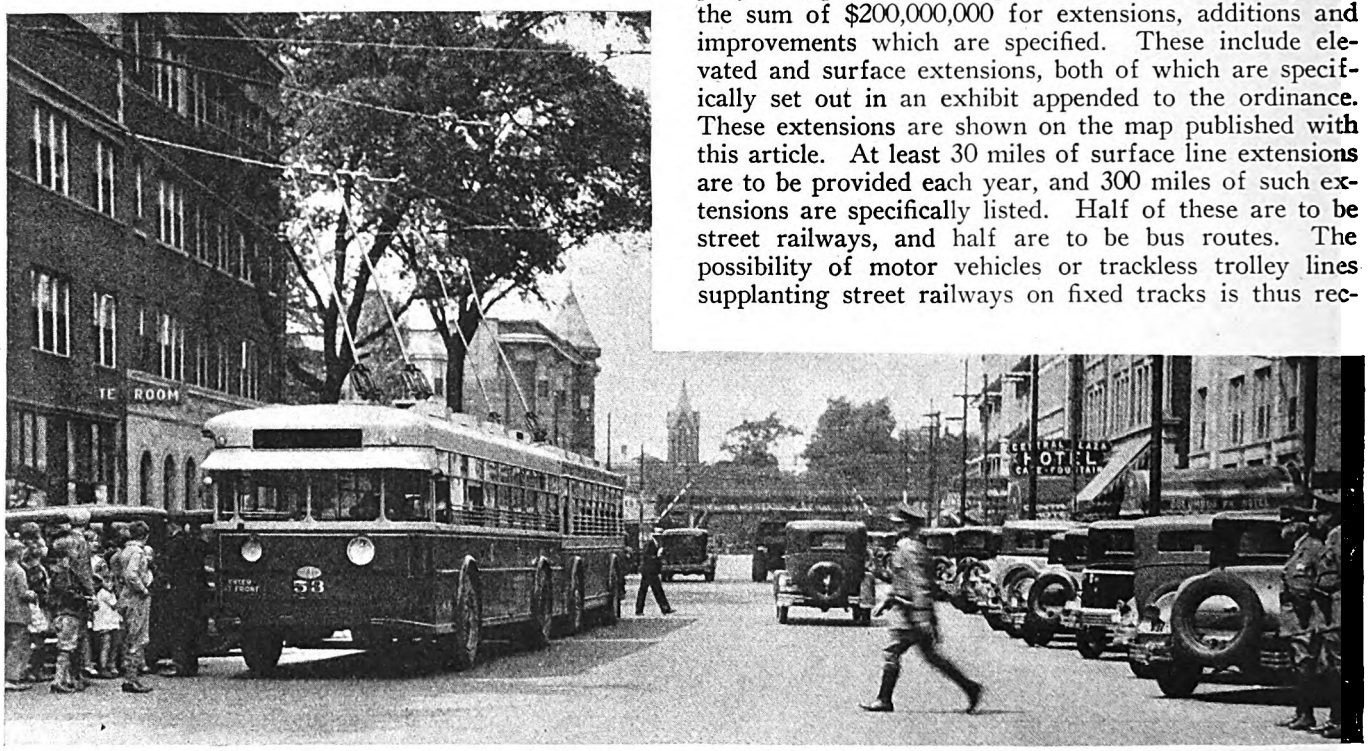
new subway; an extension from a connection with the Jackson Park branch in East 63rd Street, along the Illinois Central and the New York Central Lines to a point near the intersection of East 92nd Street and Baltimore Avenue; an extension along South Park Avenue from a connection with the Jackson Park branch in East 63rd Street, along South Park Avenue to 95th Street. The other elevated extensions are principally additional tracks on existing lines and the necessary inclines and structures to connect with city-owned subway structures.

Of the two subways, Route No. 1 will connect with the rapid transit system at a point between West Division Street and West Chicago Avenue, extending along a curve to the east, intersecting West Chicago Avenue near North Franklin Street, thence along West Chicago Avenue to North State Street, thence south along North State Street under the Chicago River to a point near East Sixteenth Street, where it will connect with the elevated structure.

Route No. 2 will connect with the elevated structure near Milwaukee Avenue, extending southeasterly along a curve to a point near West Grand Avenue and Milwaukee Avenue, thence in West Grand Avenue and under the Chicago River to a point near North Dearborn Street, thence south in North Dearborn Street under the Chicago River to a point near West Harrison Street, thence westerly along West Harrison Street under the south branch of the Chicago River to a point near Blue Island Avenue, where it will again connect with the elevated structure. This route may be changed at the option of the city by substituting West Ohio Street for West Grand Avenue, Clark Street for Dearborn Street and Polk Street for Harrison Street. Connecting subways will be provided to connect the two routes.

Not less than 1,000 additional steel or other metal cars of modern design are to be purchased for use on the rapid transit system, and not less than 1,000 additional cars or motor vehicles of modern design are to be provided for surface operation. The present rapid transit system not only will be greatly extended, but the existing plant will be improved. This will include the straightening out of the curves, the reconstruction and extension of structures, the building of new stations and platforms, the installation of escalators where needed and the elevation of the tracks of the Ravenswood branch so as to eliminate grade crossings.

General supervision of service, including extensions, additions and improvements to the new system, is vested by the statutes of Illinois in the Illinois Commerce Commission. That control will pass to the Chicago Transit Commission when such a body is created by the city. In accordance with the enabling act authorizing a terminable permit, the new ordinance requires that the company shall provide and expend, within the first ten years, the sum of $200,000,000 for extensions, additions and improvements which are specified. These include elevated and surface extensions, both of which are specifically set out in an exhibit appended to the ordinance. These extensions are shown on the map published with this article. At least 30 miles of surface line extensions are to be provided each year, and 300 miles of such extensions are specifically listed. Half of these are to be street railways, and half are to be bus routes. The possibility of motor vehicles or trackless trolley lines supplanting street railways on fixed tracks is thus recognized. Under the new ordinance the rapid transit lines in subways and on elevated structures on private right-of-way, free from the congestion of public streets, will form the essential framework of the adequate system of local transportation. The construction of the surface extensions is to proceed concurrently with the construction of the city-owned subways.



Trolley buses, the latest addition to the Chicago Surface Lines fleet, now serve 40 miles of bus lines

Removal of the elevated loop structure is not required, but the ordinance contemplates and provides for its removal in the future, whenever, by the substitution of additional subways or other facilities or the development of the transit system as a whole, the Transit Commission shall, after a hearing, find that the elevated loop structure, or any portion thereof, is no longer required by public convenience and necessity.

Provision is made for the continuance of interurban service to the center of Chicago over the rapid transit lines. The new ordinance authorizes the company to permit the use of its tracks and facilities in the subways by any company now having the right to operate over the tracks of the existing companies under operating agree-

Digitized by Google

ment. Any future agreement must be approved by the Transit Commission and must not interfere with the passenger service of the new company. Better utilization for local transportation purposes of the existing rights-of-way of steam or electric railways in Chicago and the metropolitan area have long been advocated. A section of the new ordinance expressly authorizes the new company to make operating leases or agreements for this purpose with the approval of the Transit Commission.

Detailed Provisions of the Ordinance

The ordinance as passed contains a great deal of detail and covers all of the subjects which experience has proved necessary. As published by the City Council, it comprises a 43-page folio. While it is impossible here to go into all of the details of the ordinance, the following summarization discusses the more important provisions:

Grant of Authority—The new company is granted authority to establish, construct, reconstruct, maintain and operate a comprehensive, unified local transportation system to consist of the surface lines and rapid transit systems, together with the equipment of subways, motor vehicle lines and additions and extensions thereto. The grant is to continue in force until terminated, as provided in the ordinance.

Termination of Grant—The city reserves the right to purchase the properties of the company upon six months' notice, upon the payment of a sum equal to the capital value of the transit system as fixed by the ordinance. The city also reserves the right to require the company to transfer its property to a designated permittee of the city on the same terms, except for the addition of 10 per cent if the transfer is required within the first ten years, this percentage to decrease one-tenth each year during the subsequent ten-year period. The city at any time may compel the company to comply with the terms of the ordinance through injunction, mandamus, or other appropriate proceedings in any court of competent jurisdiction.

Extensions and Improvements—In the first ten years, designated as the "initial construction period," the company is to acquire funds from the sale of securities and construct the extensions designated in Exhibit B of the ordinance. The total cost of these improvements during this period is estimated at not less than $200,000,000. During the first three years succeeding the effective date of the ordinance the company is to provide not less than $65,000,000 of this total amount for extensions and improvements. If the company fails to build the extensions, interest or dividends will not be paid either on any securities or stocks which are junior to the 3 per cent compensation paid for the use of public property, or on common stock, which, in the initial financial set-up of the bankers, represents $77,000,000 of the capital value, and this income would be applied to the building of any extensions, thus making good the default of the company. The company assumes the obligation of rendering local transportation service within the territory in all subsequent periods which the local transit commission, after hearings, shall find to be required by public convenience and necessity. It shall construct or acquire such additional extensions and additions authorized by the city and ordered by the local transit commission, after hearing.

Subways—The city agrees to construct the subways, shown in Exhibit C of the ordinance, during the initial ten-year period, the construction to be financed by special assessments levied only on properties directly benefited and from the city transit trust fund. Subsequent to the ten-year period additional subways will be built by the city in the same way. The company is obligated to equip and maintain the subways and use them as a part of the rapid transit system.

Rates of Fare—Rates of fare on the surface and elevated lines will remain the same as at present until changed by the local transit commission. Free transfers will be granted from the elevated lines to the surface lines, but a charge of 3 cents will be made for transfers from the surface lines to the elevated lines. Universal transfer privileges are provided for a continuous ride using the rapid transit lines, the surface lines or a combination, if the appropriate fare has been paid. The company is required to designate convenient and appropriate transfer points between rapid transit and surface lines, and additional transfer points may be required by the local transit commission. Employees of the company, city policemen, firemen and health department employees, when in full uniform, may ride free, and special provisions are made for letter carriers.

Paving and Clearing Away Snow—The company is required to pave the right-of-way in all paved streets occupied by its tracks, except where the city designates such an area as a parkway. All pavement on rights-of-way shall be maintained by the company. The company at its own cost must keep clear of snow the portion of the streets occupied by its tracks and provide a traffic lane on each side of its tracks, in so far as practicable. The city maintains the right to have snow, street sweepings, garbage or other street refuse transported at night on the surface lines if it so desires.

Maintenance of Property—The company is required to maintain the system in first-class operating condition. A fund representing 7 per cent of the gross receipts is to be set aside for renewal, depreciation and obsolescence. The company also is required to create a fund of 2½ per cent of its gross receipts as a damage reserve fund. The local transit commission may enter orders from time to time increasing or decreasing the per cent appropriated so that funds may be adequate to meet the needs.

Compensation to the City—The company will pay into the city transit trust fund 3 per cent of its annual gross receipts as compensation for the use of public property. For the administration of this fund the Mayor will appoint a Chicago, state or national bank or trust company, with a capital stock and surplus of at least $2,000,000, as trustee. The present city traction fund will be transferred to this new city transit trust fund within 30 days after the ordinance becomes effective.

Use of City Transit Trust Fund—Money from the fund may be used for the following purposes:

1. To pay the salaries of the Chicago Transit Commission.
2. Compensation of the trustee.
3. The sums authorized by the City Council to meet the cost of the construction of subways provided in Section 9.
4. The sums authorized by the City Council "to pay expenses of the city in connection with the protection of the rights of the city or the enforcement of the company's duties and obligations under this ordinance."
5. Sums required for the cost of renewal or replacement of any destroyed portions of the subway.
6. The cost of the city's share of relocating company's tracks, as ordered by the transit commission.
7. The cost of any additional subways, and the sums required to complete the final purchase of the property of the company.

Employee Pensions—The company must establish and maintain a pension system upon such terms as the company and its employees may agree, subject to the approval of the local transit commission. Reasonable life and health insurance for employees also must be provided out of the operating expenses of the system.

Value of Properties—The value of the properties of the surface lines and rapid transit company as of Aug. 31, 1929, is agreed to be $260,442,063.82, "to which may be added such amount as the Illinois Commerce Commission may approve to meet the working capital requirements of the company." It is agreed that this sum will be augmented by additions to capital value and from it will be subtracted deductions in capital value, made between Aug. 31, 1929, and the effective date of the ordinance, and the total thus obtained shall be the initial capital value. Subsequent additions to the initial capital value must be approved by the local transit commission, and this initial capital value, plus all additions and less all deductions or reductions of capital value, shall constitute the true capital value of the company's property, which will be taken as the actual net investment of the company in determining the basis for fixing rates of fare and return to the company. Additions to the capital account are confined to actual expenditures for new additions.

Return to the Company—It is agreed that the company is entitled to, and shall receive, a just and reasonable return, to be fixed from time to time by order of the local transit commission. If the corporate income of the company in any fiscal year is in excess of the return so fixed, the excess will be paid into the city transit trust fund as additional compensation to the city.

Approval of the Ordinance—The ordinance will not be in full force unless:

1. It be approved at the referendum vote on July 1, 1930.
2. The Illinois Commerce Commission authorizes the purchase of the properties and the issuance of securities as provided in the ordinance.
3. The company accepts within 120 days after the referendum.

There are four exhibits which are part of the ordinance. Exhibit A lists the properties of the surface and rapid transit lines now owned which are to be acquired by the new company. Exhibit B lists the extensions and additions provided for the initial ten-year period. These are shown in the map published with this article. Exhibit C provides the routes of the proposed subway structures. Exhibit D lists the bonds of the Chicago Rapid Transit Company which will continue as liens until maturity.

C.E.R.A. Analyzes Condition of the Industry

IN VIEW of the serious decline in riding and revenue accompanying the present business depression, the Central Electric Railway Association, which convened at Cedar Point, Ohio, on July 17 and 18, devoted a major part of its program to a discussion and analysis of the situation. It was the general opinion of the body that although the depression had caused great losses to all transportation companies and an immediate upturn could not be expected, the economy measures instituted and service adjustments made to offset these declines would yield increasing and continuing benefits to the railways with a return to normalcy. The trolley bus, taxation and modern braking were other subjects presented.

The meetings were conducted under the chairmanship of the association president, L. G. Tighe. In his opening address Mr. Tighe commented on the present condition of the industry and summarized the replies to a letter sent to several member companies to gain a cross-section of the industry's status. With the exception of two, all the companies reported serious falling off in passenger and freight revenue and unfavorable industrial conditions in their territories. The replies revealed, however, the many steps being taken to hold up the net. Increasing speed, improving equipment, rearranging routes, eliminating stops, abandoning unprofitable lines, adjusting fare schedules, affecting all economies possible, merchandising rides, giving pick-up and delivery freight service and making the service generally more attractive are some of the activities Mr. Tighe reported.

"Look beyond the present" was the counsel of G. C. Hecker, general secretary American Electric Railway Association, in his address on the general situation of the industry and the San Francisco convention high spots. In spite of all the adverse figures, he related, optimism prevailed at the Coast meeting. This was prompted by the general feeling that an upturn would be witnessed in the fall, and by the progressive moves being made to develop new cars, secure adequate fares and meet the competition of the private automobile. Mr. Hecker told of the Presidents' Conference plan, announced at the convention, the purpose of the organization and its plan of attacking the problem. He stated that progress necessarily would be slow and added that companies should not defer car purchases.

Another encouraging factor, the speaker pointed out, is the rapid approach of the private automobile to its saturation point. Leaders of the automotive industry expect a stabilization in the manufacture of their product very soon, a condition which will have a vital influence on the electric railway riding habit. In the meantime, Mr. Hecker added, the railways should give the most in speed, comfort and convenience to approach automotive service.

The speaker commented on the wide variation in maintenance costs, the opportunities for interchange of ideas and the adoption of new practices, the problems facing the small cities and the development of freight business.

The convention was addressed next by W. J. Clardy, Westinghouse Electric & Manufacturing Company, who spoke on the trolley bus. "A new form of successful transportation without rails," he stated, "has been introduced by the modern trolley bus. This vehicle is permitting the economic expansion of the field of street railway business and is a much-needed tool for increasing transportation revenues. It offers a means of providing service in smaller cities or extending into new territory in larger cities, with a reasonable investment and low operating cost. The outstanding factor in favor of the trolley bus is that its application has resulted in increased gross receipts. It appeals to both the public and operating men."

The subject was discussed also by C. A. Burleson, General Electric Company; L. M. Zapp, Eastern Michigan Railways; G. C. Hecker, A.E.R.A.; R. N. Graham, Penn-Ohio System, and Ross Schram, Twin Coach Corporation.

"Transportation and the Finest Motive in the World," was the subject of an address at the second session by Allan Rogers, supervisor public relations New York Central Lines. Mr. Rogers commented on the essentiality of the industry and stated that the public really is interested in transportation. Enthusiasm, according to the speaker, is the greatest need of both the steam railroads and electric railways to forge ahead. "Have faith in your industry and confidence in yourself," was the counsel added. Mr. Rogers urged the development of new business and spoke at some length on "taxation without due compensation."

Following Mr. Rogers' address a paper was presented by G. L. Cotter, engineer Westinghouse Traction Brake Company, on "Modern Braking of Electric Railway Cars." "Traffic density during the past few years," Mr. Cotter stated, "has seriously affected average schedule speeds of street railway cars. Inability to start and stop as quickly as other vehicles has caused a slowing down to permit safe operation. This can be remedied, however, by improving the car brakes. The more nearly the street car approaches the stopping ability of the automobile, the better it is prepared to hold its place in the traffic stream. By modernizing the brake equipment the stopping distance can be decreased 40 to 50 per cent.

"Since there are thousands of old cars in service, a great improvement in average braking performance on any railway can be obtained by modernizing the equipment. This involves, first, the reduction of time of application and release from the three to five second rate to the recent standard of one second or less, and second, bringing the braking force nearer the point of wheel sliding than has been the practice."

The convention was concluded with an interesting symposium on "What's Ahead for the Industry." Those who participated were: Charles H. Jones, Chicago, South Shore & South Bend Railroad; R. R. Smith, Northern Indiana Railways, Inc.; H. A. Nicholl, Union Traction Company of Indiana; L. M. Brown, Interstate Public Service Company; R. N. Graham, Penn-Ohio System; Claude L. Van Auken, *Electric Traction*; Clifford A. Faust, ELECTRIC RAILWAY JOURNAL; L. M. Zapp, Eastern Michigan Railways; T. A. Ferneding, Dayton-Xenia Railway; W. S. Rodger, Eastern Michigan Railways; G. C. Hecker, A.E.R.A.; W. H. Beattys, Westinghouse Electric & Manufacturing Company; James H. Drew, Ohio Brass Company, and R. H. Palmer, Westinghouse Electric & Manufacturing Company.

Maintenance train used on the overhead system of the New Haven's main line

Maintaining the DISTRIBUTION SYSTEM *of an Electrified Railroad*

By B. F. BARDO

Superintendent of Electric Transmission, New York, New Haven & Hartford Railroad

Reliability is considered of the greatest importance on the New Haven Railroad's electrified division. Particular precautions are taken to eliminate defects in the power distribution system before they may cause interruptions to train service

RELIABILITY that is required in railroad service is of such a high degree that everything must be done to put the distribution plant of an electrified system in the best shape possible and to keep it so. Electric motive power is helpless without a supply of energy.

The electrification of the New Haven Railroad, while not the largest in this country from the standpoint of route-miles, is perhaps the most comprehensive one in the United States at the present time. In round numbers, the company owns 583 miles of electrified track, distributed as shown in Table I. The location of lines and the dates of electrification are given in one of the accompanying diagrams.

The contact and feeder wires have a voltage of 22,000 between them, with 11,000 volts from each to the rail return. As a rule, both the feeder and contact wires are supported from the same structures, which are of steel and spaced a nominal distance of 300 ft. apart. On all except the New Canaan and Danbury branches the feeder system is in duplicate, two No. 0000 wires being on each side of the right-of-way.

Power for signals is carried on duplicate single-phase, two-wire No. 00 circuits. Most of these operate at 11,000 volts, although those west of New Rochelle and on the New Canaan branch carry 2,300 volts. Duplicate single-phase one-wire No. 00 circuits at 11,000 volts carry power for circuit breaker control between Harlem River, Woodlawn and New Haven. Between South Norwalk and New Rochelle there are also two three-phase, three-wire 11,000-volt No. 0000 circuits, and between New Rochelle and Oak Point similar circuits, but of No. 00 wire. Throughout the electrified territory low-voltage multiple conductor signal cables are suspended by steel messengers from the main supporting

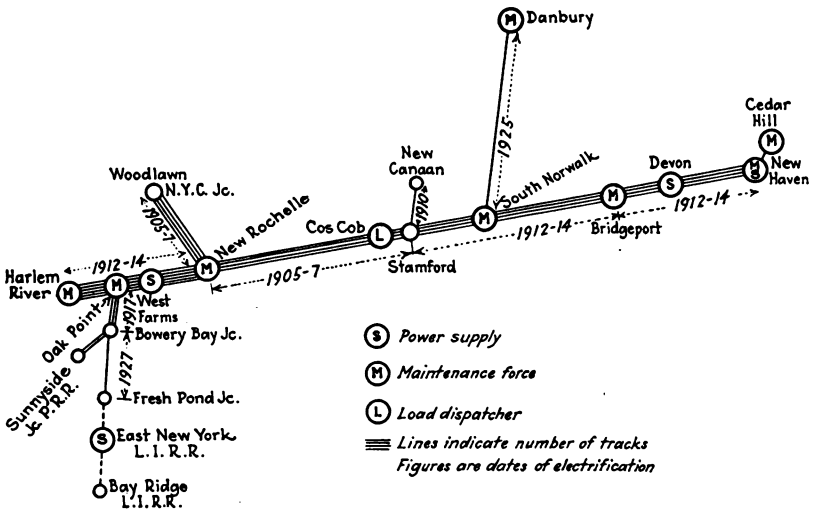
One signal feeder, single phase, two wire	12
One signal power cable, two and four wire	12
Two control feeders, single phase, one wire	75

structures. The different types of circuits and mileages are shown in Table II.

Contact and feeder systems are sectionalized at 26 points, most of which are interlocking signal stations. More than 700 oil circuit breakers are involved, all remotely controlled and practically all automatic. There are about the same number of disconnecting switches. All of the oil breakers and about half of the disconnecting switches are under the control of the load dispatchers.



Schematic diagram of the New Haven's electrified system, showing locations of power supply, maintenance forces and load dispatchers

Power Generated and Also Purchased

The principal source of power is the company's steam station at Cos Cob, Conn. Supplementary supplies are obtained from the United Electric Light & Power Company through a joint substation at West Farms, N. Y., and the Connecticut Light & Power Company at Devon, Conn. Emergency connections of limited capacity are maintained to the Connecticut Company at New Haven and the Long Island Railroad at East New York.

The normal daily traffic includes 264 passenger trains on both main and branch lines, and an average of about 37 freight trains. In addition there are the usual work trains and light engine movements. All yards, both freight and passenger, west of Stamford are operated entirely by electric switchers. East of Stamford both steam and electric switching is employed.

Operation, maintenance and construction of the entire distribution system are handled by an organization which is shown in detail in the accompanying chart. Besides the general officers, two general foremen are in charge of all maintenance and construction in the territory east and west of Stamford respectively. The chief load dispatcher and his assistants are located at Cos Cob.

Each fall a close-up inspection of the entire catenary and contact system is made. Each spring a similar inspection is made at interlocking plants and also where the service is known to be sereve. Trains are used from the tops of which the inspection is made. The various items requiring attention are recorded and later are used to form a work list for each individual electric section.

The indicated maintenance items are done in order of their importance with a view of preventing a plant failure. If maintenance items of a similar nature occur in any quantity they are programmed and the material prepared in advance. Sometimes special facilities must be employed to be sure to get the work done before difficulties arise. It is far simpler to schedule, say, a 30-minute maintenance job in the middle of relatively dense service than to run the risk of a plant failure at an unknown time with repairs which may take hours. As a result there are but few preventable failures.

Each summer a survey is made of the entire electric zone to determine the height of the contact wire above the rail under each overhead highway bridge. All locations lower than 16 ft. are inspected to ascertain what must be done to increase the clearance to that value. The distance from contact wire to rail tends to decrease due to several causes, the more important of which are: (1) Slack catenary messengers or trolley or overlong hangers; (2) raising the rail more or less unconsciously during track tamping; (3) replacing rail and tie plates with new material of greater over-all height.

The results of the clearance survey are kept for reference when a question is raised as to the possibility of moving an over-dimension car. A published permissible height for cars may be 15 ft. 7 in., based on a nominal limiting clearance between contact wire and rail of 16 ft. Over-dimension cars may be routed from one track to another, or even handled under dead wire if that appears better than reloading.

Besides general annual inspections there are intermediate schedule inspections of special parts.

During the five-year period 1925-1929 the time of our maintenance trains was distributed as shown in Table III. Ordinarily these trains are manned by one foreman and three linemen. We have tried to make the train equipment as complete as possible: The trains have been designed for speed in doing the work, because that actually makes the time more productive. They operate both day and night and are electrically lighted, the equipment including floodlights and one portable 6-volt storage battery lamp. The elevating platform of the tower car is operated by a compressed air motor. Compressed air is also used for operating wrenches and for drilling. Each train is equipped with a forge, drill press, rod shear, automatic die heads for threading rods up to ½ in., and other small tools. Oxyacetylene cutting and weld-

Table III—Distribution of Time of Maintenance Trains on New Haven Electrified System, in Hours

	1925	1926	1927	1928	1929

Digitized by Google

ing equipment is carried. We also are experimenting with a compressed air operated pay-out and pick-up reel holding about 5,000 ft. of two-conductor, rubber-insulated cable, by means of which our train can keep in touch by telephone with the load dispatcher.

In the yards and on the branch lines the basis of maintenance effort is the periodic inspection. In the four major yards the personnel consists of an emergency foreman with a lineman and a helper on the day trick, supplemented by an electric switch operator on each of the other two tricks. The Danbury branch has a crew similar to that used in yards on the day trick. At the Oak Point and Cedar Hill yards and on the Danbury branch a gas rail-and-tower car combination, as shown in one of the illustrations is used. This equipment covers the ground readily and provides a well-equipped point from which to work.

Substation or anchor bridge maintenance includes all inspection and repair work on breakers, disconnecting switches, transformers, control cables, switchboards and other equipment at sectionalizing points. In the inspections every attempt is made to ferret out faulty conditions before failures occur. Oil circuit breakers are inspected internally after closing once on a short circuit, or after opening six times under short circuit conditions. Exceptions are the circuit breakers on stub-end circuits, which are inspected after each operation under short circuit conditions. An individual card for each piece of major substation equipment carries a brief record of the inspection and maintenance of that piece.

Insulating oil in large transformers is sampled every six months. If the average of three samples from the bottom of any tank fails to exceed the minimum breakdown limit, two to four barrels are drawn off from the bottom, a like amount of new oil added, and another test made. Every two years the oil is filtered by a portable centrifuge. Circuit-breaker oil is changed every two years unless more frequent replacement is necessary on account of operating developments. The bus supporting and other pin and suspension insulators at all anchor bridges are tested annually by a standard device, and defective ones scheduled for replacement. Operation of all relays is checked twice yearly.

Safety Methods Are Stressed

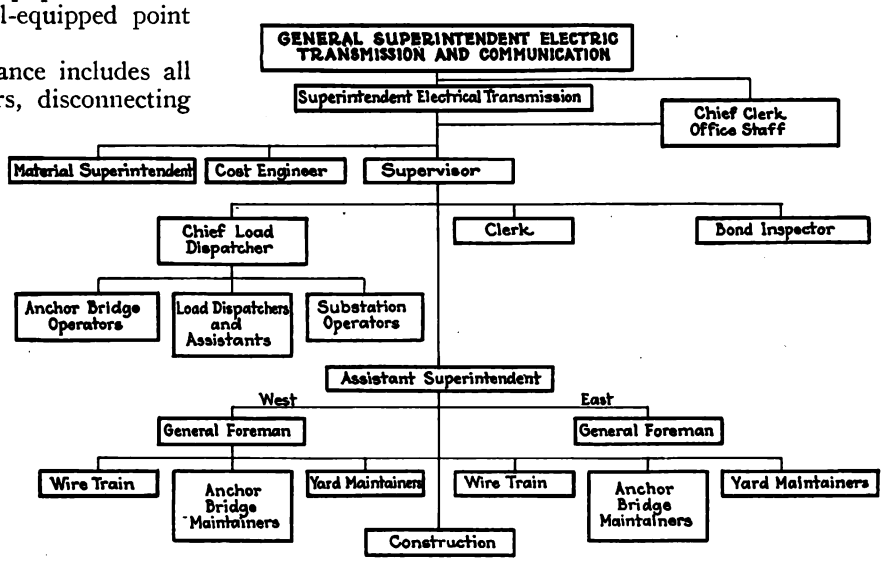
Safety of employees is given considerable attention. No work is done on wires of the traction distribution system until they are de-energized and grounded, usually at two or more points. Each employee must pass an examination on the more important of the safety rules. In addition safety officers must qualify on certain fundamental rules of the operating department.

Practices known to be safe are developed in detail and the forces are instructed in their use. Cards are used for reporting practices or conditions which are considered unsafe. These are referred for correction to the department involved, and are made the subject of comment at the regular monthly safety committee meeting, of which the general superintendent of electric transmission and communication is chairman and most of the supervising officials are members. In addition, all accidents are analyzed.

Besides these meetings, other monthly meetings, lasting about one hour, are held by field forces. At these meetings safety rules, accident analyses and first-aid work are handled. Since 1928 a course in first aid has been available. A number of the department employees hold Red Cross certificates.

Method of System Operation Standardized

Operation of the distribution system, which handles about 200,000,000 kw.-hr. per year, differs from that of a power company principally in that the system is broken up into very much smaller parts. The chief load dispatcher at Cos Cob is assisted by four load dispatchers and two assistant load dispatchers covering the 24-hour



The organization of the electric transmission department of the New Haven Railroad

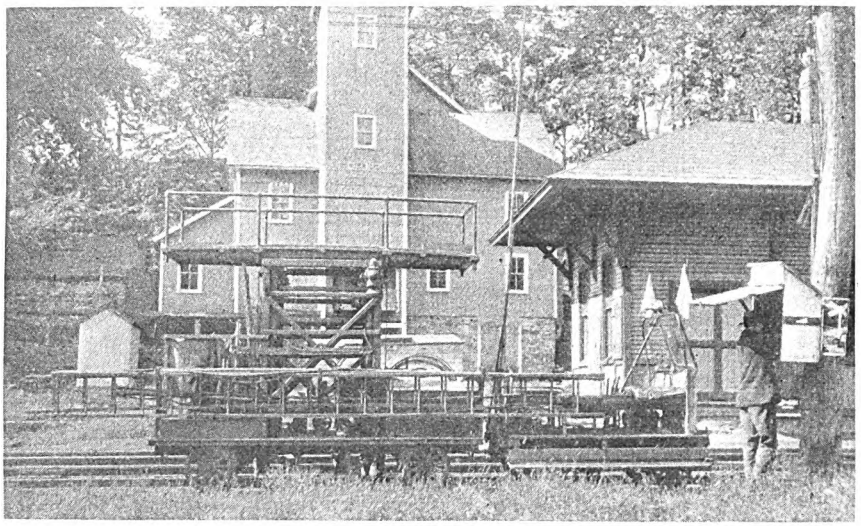
period. The two principal duties of the load dispatchers are: (1) Isolation of faults, and (2) procuring track, feeder or other circuits for maintenance and construction forces in co-operation with operating department officials.

In the isolation of faults the load dispatchers are assisted principally by reports from signal station operators, who control all sectionalizing breakers. A fault or ground is cleared by the automatic opening of circuit breakers at adjacent signal stations. The operators report immediately by selector type telephone to the load dispatcher, who proceeds to energize those circuits which do not appear to be directly involved. In general, it is the practice to close main line and yard traction circuit breakers directly on the fault, but this is usually done immediately and only once. Faulty traction circuits are left de-energized if reports to the load dispatcher disclose clearly the nature of the trouble. Faulty feeder circuits usually are left open until after an inspection to locate the difficutly. Fautly traction circuits on the single-track New Canaan and Danbury branches normally are tested once. If they do not show clear they are left de-energized until a member of a train crew reports. The load dispatcher instructs the crews to drop the pantographs, after which the circuit is tested again. If the branch then shows clear, the inference is that there was difficulty with the locomotive and the crew is informed accordingly. If no trains are on such single-track branches additional tests may be made at the option of the load dispatcher, but an inspection is always ordered as soon as possible.

Maintenance and construction forces inform the load

Digitized by Google

dispatcher as to the extent of the circuits or equipment they require, and for how long. When traction circuits are involved the load dispatcher consults the train dispatcher. After mutual agreement has been reached the load dispatcher has the necessary circuits de-energized and so informs the foreman or assistant foreman of the gang involved. The foreman enters the time and the description of the circuit or circuits in his log book and has them grounded for protection. He gives each man who is to work on or near them a copy of the log or clearance slip. When the work is finished the log slips are taken back, the protective grounds removed, and the circuit or circuits turned back to the load dispatcher.



In the yards and on the branch lines gas rail tower cars are used

When employees of other departments or outside contractors have much work to do for which circuits of one kind or another must be de-energized and grounded, an employee familiar with the system is assigned to prescribe safe working space and to procure and ground such circuits as may be necessary.

Besides their principal duties load dispatchers have several others. All remote controlled circuit breakers are daily put through a complete cycle of operation, usually during the early part of the second trick. If any circuit breakers misbehave, repairmen are then available to fix them. On days of special traffic, such as football days or those preceding holidays, this test is omitted. Once every 24 hours the load dispatcher requests each signal station operator to inspect his switchboard and report all open circuit breakers. This check catches any breakers which are open or closed incorrectly.

Interference with radio reception is a source of little difficulty with us, although any arcing contacts usually will affect nearby reception. Fuses, disconnecting switches, poorly fitted catenary hardware and devices for feeding the draw span of bridges cause practically all of the difficulty. A small radio head set in the load dispatcher's tower is used to indicate trouble. A portable test receiver is used by the bond inspector to locate difficulties not readily apparent. A complete record is kept of every radio reception complaint investigated.

Firemen who are fighting fires contiguous to, or on, the right-of-way must be protected. The fire departments of all communities served by the electrified section have been informed on whom to call if the fire requires de-energizing of wires. In the event of a call of this kind it may be necessary to de-energize all wires by the scene of the fire for a short period. Responsible officers of the operating or distribution departments are hurried to the scene of the fire to take steps for restoring normal service.

To assist in clearing up after wrecks or other emergencies, a car of wood poles and a framed wood bent is kept available at New Rochelle. At Bridgeport and New Rochelle two circuit breakers are held completely assembled ready for immediate use. There is also a section of control switchboard with the usual equipment ready for wiring, and operating circuit breakers. A spare 2,000-kva. balancing transformer is kept on a special car at New Rochelle, with equipment for installing it quickly. Spare small transformers and other equipment are available at both New Rochelle and Bridgeport.

The total number of grounds and preventable defects for the latest five-year period available is given in Table IV. This table sets forth grounds as differentiated from faults. For instance, an insulator, particularly of the wood strain type, may flash over a number of times before definitely failing. There is only one fault but a number of grounds. Every fault is investigated so that it may be properly classified as between preventable and otherwise, and that so far as possible steps may be taken to prevent a recurrence.

Table IV—Total Number of Grounds and Preventable Defects on New Haven Electrified System, 1925–1929

Commercial Frequency for Single-Phase Road

EXPERIMENTS are being made in Germany with single-phase current of commercial frequency for railway service. Two locomotives have been built and are being tried on an industrial railroad, according to *Elektrotechnische Zeitschrift*. The locomotives are capable of starting a train of 1,400 tons 60 times an hour in either direction, with control no more difficult to operate than that of a direct-current locomotive.

The power is developed from single-phase compensated motors in conjunction with three-phase motors. On the first control step the single-phase motor is connected in cascade with a three-phase motor of the same number of poles. For reversing, advantage is taken of the characteristic of the induction motor whereby it turns in the direction of the rotating field when fed through the stator and opposed when fed through the rotor.

For starting, the converter is started first to supply direct-current for excitation of an intermediate rotor. When this attains synchronism the locomotive is ready to start. The control is actuated with direct current converted on the locomotive

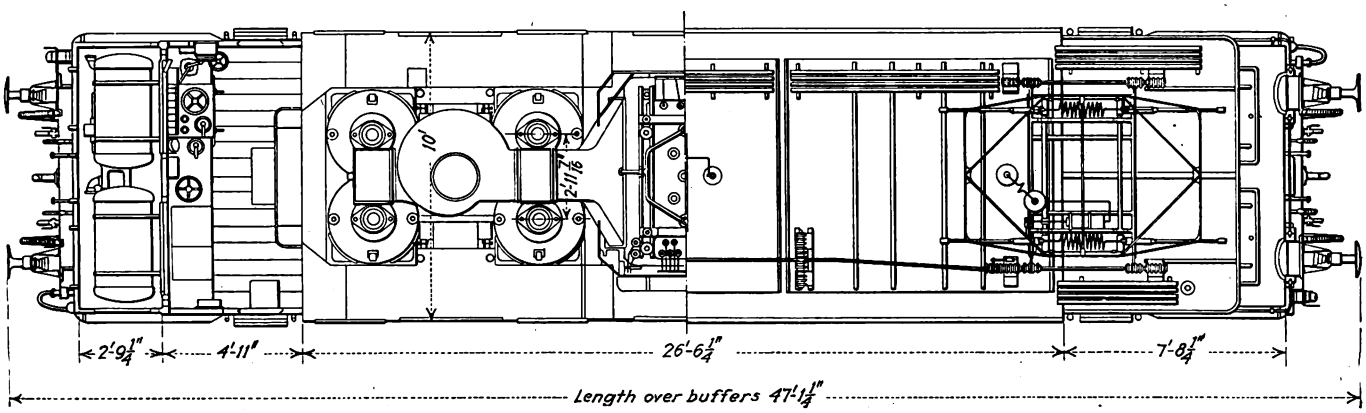
One of the new Austrian Federal Railways locomotives with vertical twin motors



The twin motors drive individual axles. As they are within the cab they are readily accessible

Vertical Motors Feature Austrian Locomotives

Built for high-speed passenger service, twin motors drive individual axles through bevel gears

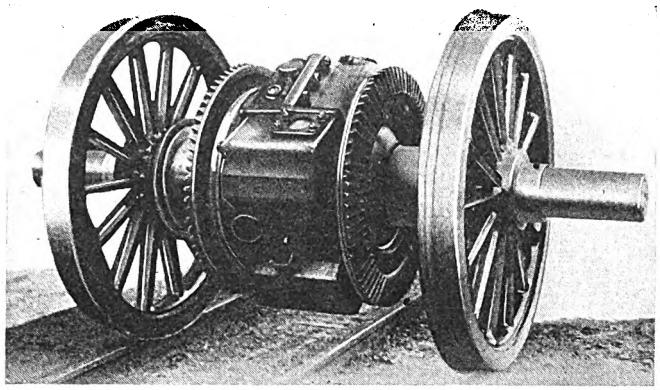
LOCOMOTIVE drive of a type differing radically from that in use in America has been found successful on the lines of the Austrian Federal Railways. The principal feature is the use of vertical motors connected to the driving axles through bevel gears. The drive is somewhat similar to that brought out a short time previously by the Midi Railway of France.

At first, the Austrian Federal Railways bought four locomotives of the vertical type. These had four driving axles, with a motor mounted above each. The satisfactory performance prompted the railway to adopt a similar design for use in high-speed passenger service on the Innsbruck-Salzburg division of the main line. This section has grades up to 2.5 per cent and curves with a minimum radius of 225 meters (75 ft.), over which trains of 360 tons are hauled at speeds of about 70 km. (42 miles) per hour. Since it was desired to run the trains through without change of motive power and to attain the highest schedule possible, it was deemed advisable to increase the rating.

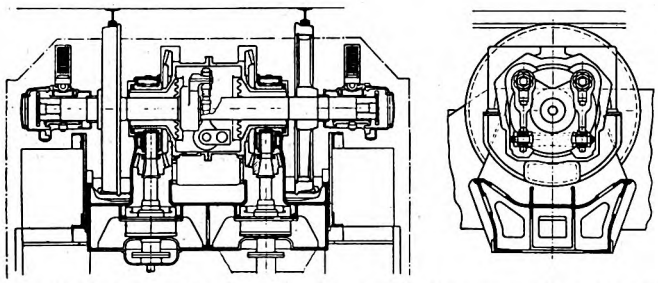
Both types of locomotives have the same general arrangement of parts. The new type, of which 29 are now in service, differs from the earlier design principally in having twin motors geared to each axle. Each axle carries a quill which is flexibly mounted through links. At each end is a bevel gear, held in a fixed position with respect to the motor and the locomotive frame. The driving mechanism is completely housed in a drum-shaped casing.

The flexible links between quill and axle are carried inside the drum. Two guiding rods are linked on one side to two arms on a short shaft carried in bearings within the drum, the other ends of the rods being connected to two crankpins mounted on arms projecting

Digitized by Google



Assembly of a driving axle showing the inclosed flexible links and the twin bevel gears



Detail of the flexible drive. The double-link connection permits of considerable motion between wheels and body of the locomotive

from the driving axle. Ball joints at either end of the rods provide full flexibility in every direction between the driving wheels and the spring-supported unit of body, motors and quills.

The bevel gears are of the helical type, and are said to be extremely smooth and quiet in action. There is a twin-step bearing on each motor shaft to absorb the vertical thrust.

Location of the motors within the cab makes the commutators and brushes accessible even when the locomotive is in motion. The high center of gravity gives good riding qualities at high speeds. The available lateral play of the drivers permits the use of a leading truck at either end of the locomotive, with one idle axle and one driving axle. With the low unsprung weight and small-diameter wheels, the wheelbase was made short, and easy guiding over the sharp curves on the mountain division was made possible.

The principal reason for the change from the single motor to the twin motor design was the need for an increased output. The twin motors weigh only slightly more than a single motor. Due to the smaller armature diameter, the rotating masses are smaller and the inertia effect is reduced, making acceleration and retardation easier. The gyratory effect in each group is compensated by having the motors equally spaced about the center line.

The motors are connected permanently in series. It has been suggested that the same locomotive design can be adopted for freight service with the motors connected for half speed, although this has not been done as yet.

Following are the specifications of the locomotives:

Specifications of High-Speed Locomotives of Austrian Federal Railway

Electric system	Series 1570 Single-phase, 15,000 volts, 16⅔ cycles	Series 1670
Number of units	4	29
Diameter of drivers, in.	53½	53½
Wheelbase, ft.-in.	36–2	36–2
Length between buffers, ft.-in.	46–0	47–2
Number of motors	4	8
Motor voltage	385	385
Gear ratio	1:3.82	1:3.82
Continuous transformer output, kva.	1,550	2,840
Continuous locomotive output, kw.	1,270	2,200
One-hour locomotive output, kw.	1,650	2,440
Speed at continuous rating, m.p.h.	41	45
Speed at one-hour rating, m.p.h.	35	41
Maximum safe speed, m.p.h.	53	67
Tractive effort at starting, lb.	37,500	42,000
Weight, mechanical equipment, tons.	57.2	56.7
Weight, electrical equipment, tons	44.0	49.0
Weight total, tons	101.2	105.7

British Subway Tries Roller Bearings

ROLLER bearings on electric cars have just been put into service by the Metropolitan Railway, of London. This is the first use of bearings of this type on electric trains in the United Kingdom. If they prove satisfactory, as seems likely, they are to become standard equipment on this subway.

The roller-bearing axle boxes and motors of these trains are the result of intensive research, and constitute a radical departure from conventional design. They give promise of substantial economies, together with greater mechanical efficiency, smoother running and quicker acceleration. Attention to lubrication is said to be necessary only about once a year. The reduction in train resistance will, it is hoped, lower the demand for electrical energy on starting, give increased speed without involving the risk of hot bearings, and also permit the introduction of heavier trains.

It is not without interest that the company is returning to the compartment type of coach, which it now regards as affording the speediest method of discharging and loading passengers.

Bonus Plan Works Well

on New York & Queens County Railway

Receipts have been increased, accidents have been reduced and employment has been stabilized since employees have shared in earnings

BONUSES for certain classes of employees, based upon earnings, have contributed measurably toward the successful operation of the New York & Queens County Railway during the past seven years. When Gen. Lincoln C. Andrews assumed control of the property, in 1923, the receipts of the company were the lowest per car-mile of any of the street railways in the New York metropolitan area, averaging just over 29 cents. Setting a quota of 31 cents per car-mile, the management agreed that for every cent per mile which the property should earn above this figure, certain of the employees should have their base rate of pay increased 1 cent per hour. Those participating include all platform men and supervisors, all employees of the shops and mechanical department excepting the superintendents, all employees of the line department, and all substation employees. Trackmen are not included because the track force is a seasonal one and few of the men employed in this capacity remain with the company for more than a few months at a time.

To be eligible, an employee of the transportation department must work at least 150 hours each month. In order to stimulate interest in safety and to reduce accident expenditures, it has been further provided that trainmen involved in accidents for which they are at fault shall lose their bonus for the month. Shop employees responsible for poor maintenance resulting in pull-ins, etc., may also be penalized in this way at the discretion of the management.

From the very inception of the plan receipts began to exceed the figure of 31 cents per car-mile, making the bonus plan operative at once, and this continued with only one break until August, 1924. During the latter part of 1924 and the first half of 1925 receipts fell below the quota figure and no bonus was paid. When the company sought, and obtained, an increase in fare from 5 cents to 6 cents, effective in July, 1924, the basis of the bonus was raised to 37 cents per car-mile. Receipts have run above this figure continuously for the last 52 months, reaching a maximum of 46.75 cents per mile, as shown in the accompanying table.

When the Interborough Rapid Transit subway was extended to Flushing in 1928, it was thought that the receipts of the New York & Queens County Railway would suffer a severe decline, but the rapid development of the community has prevented this. Certain unprofitable lines were abandoned and service on others was reduced, with the result that neither receipts per car-mile nor the gross receipts of the company have suffered to any extent.

Under the original plan, the money earned in the form of a bonus was made available and was included in each payroll, being based upon the earnings of the previous month. Effective Jan. 1, 1929, however, the plan was altered so as to permit men to leave the bonus on deposit in a savings bank to be paid in a lump sum, plus 4½ per cent interest, at the end of the year. It was also provided that those choosing to do so could have the bonus paid monthly as had previously been the practice.

Monthly Bonus Payments, in Cents per Car-Mile, by New York & Queens County Railway

	1923	1924	1925	1926	1927	1928	1929	1930
January	.....	0.013	.....	.....	0.0450	0.0425	0.0375	0.0425

March	.....	.....	.....	0.007	.0370	.0475	.0525	.0375
April	.....	.016	.....	.011	.0500	.0500	.0625	.0500
May	.....	.025	.....	.026	.0690	.0625	.0675	.0675
June	.....	.046	0.012	.054	.0740	.0975	.0525	.0575
July	.....	.036	.006	.047	.0310	.0800	.0325	
August	0.014	.008	.008	.023	.0375	.0650	.0225	
September	.015	.....	.034	.030	.0450	.0525	.0500	
October	.018	.007	.050	.050	.0800	.0850	.0500	
November	.008	.....	.027	.029	.0575	.0475	.0475	
December	.006	.....	.....	.047	.0400	.0375	.0500	

Two weeks before Christmas, 1929, a general distribution was made of the bonuses which had accumulated during the year. The total amount distributed in this manner was approximately $9,000. Through the monthly payrolls an amount even greater had been distributed, the total bonus payments for the year aggregating $21,531. The amount of the individual bonuses varied, the highest three awarded being respectively $184, $177 and $174.

Every day the receipts per car-mile of the previous day are posted in the trainmen's quarters at the carhouse. The cumulative earnings of the month are also published, so that the men can determine very closely, from day to day, just what the month's bonus is going to be. The entire force takes a lively interest in this and follows the company's fortunes closely.

Edward A. Roberts, general manager of the property, is convinced that the men are making a real effort to increase the company's business, and that their efforts along this line are largely responsible for the success that has been attained. He is also convinced that the accident clause in the agreement with the men has had a salutary effect. In order to clear themselves of responsibility, the trainmen are provided with "my own fault" cards, upon which they secure, if possible, the signatures of drivers or others with whom they become involved in accidents. This practice has proved effective in reducing damage settlements, the expense of which, during the past year, totaled less than 1 per cent of the gross receipts. Since the bonus plan was inaugurated there have been no labor troubles of any description, and the management believes that the plan has had the effect of stabilizing employment, particularly among the older trainmen and shop employees.

Employee PENSION PLANS

Survey covering 27 electric railways shows unanimous agreement concerning desirability of pensions. In almost all instances entire cost is carried by company, and difficulties are anticipated as number of eligibles increases.

PENSIONS for veteran employees and methods of financing such an arrangement have been receiving more and more attention from electric railway executives during recent years. On some properties pension plans have been in effect for more than twenty years, and on a considerable number they have been in effect for ten or fifteen years. Recently has come the discovery that the payment of benefits is exceeding the early estimates, and the annual appropriations for pension purposes are assuming considerable proportions. It appears likely that this problem will become more serious as time goes on. For the purpose of determining the facts of the situation, and to secure the opinions of executives of companies where pension plans are in effect, ELECTRIC RAILWAY JOURNAL has made a survey covering more than a score of such properties in the United States and Canada.

Considerable similarity in the experience of the various companies was disclosed by the survey. Without exception the executives expressed the opinion that a pension plan of some kind is desirable. At present very few of the railways have established any reserve to meet pension requirements. The almost universal practice is to make payments from current earnings. As the number of employees eligible for pensions has increased, this policy has created a serious problem. A majority of the executives believe that the present plan is not satisfactory, but opinions vary concerning steps which should be taken to improve the situation.

Discussing the desirability of pensions, J. N. Shannahan, president Omaha & Council Bluffs Street Railway, states: "In general, I consider a pension plan for old employees a necessary arrangement, and if there were none in effect I am sure we would have to take steps toward the adoption of one." A similar opinion is expressed by K. B. Thornton, general manager Montreal Tramways, who says: "I believe that it is only fair and right that the company should grant a pension to employees after a period of 25 years of faithful service, and I think that the company should devise some means whereby it can be provided."

A pension plan is very desirable both for the company and for the employees, according to T. Julian McGill, vice-president Twin City Rapid Transit Company. On this subject he says: "It is quite impossible to discharge men who have become too old or too disabled to perform a satisfactory day's work after they have worked for a company for many years. Without pensions, such situations require donations or special jobs, making somewhat of a beggar of the employee and naturally decreasing the efficiency of the company. We consider an old-age pension essential both from a business and a humane standpoint."

Speaking for the Washington Railway & Electric Company, H. C. Kimball, assistant to the comptroller, says: "We consider a pension plan to be a practical and satisfactory arrangement and we would favor the establishment of the same if we did not already have one in effect." Similar sentiments are voiced by F. L. Butler, vice-president Georgia Power Company; Fred D. Gordon, vice-president and general manager Cumberland County Power & Light Company; C. C. Vargas, vice-president Key System Transit Company; Elton S. Wilde, president Union Street Railway, New Bedford, Mass., M. H. Parkinson, auditor Municipal Service Company, Altoona, Pa., and Hugh J. Sheeran, president New York Railways Corporation.

AGE AND SERVICE REQUIREMENTS

In general the pension plans in effect in the electric railway industry stipulate an age limit for retirement of from 60 to 70 years, with a requirement of from 20 to 25 years of continuous service. Continuous employment, however, appears to be variously interpreted. On some properties a lapse of employment of six months to a year is provided; with other companies a longer period is allowed, provided the man's service record is satisfactory. The majority of plans provide for disability retirement at an earlier age, or with a lesser period of service. Certain properties also give wide discretionary powers to a "pension committee," so that execptions may be made in meritorious cases. The Boston Elevated even provides for the extension of pension benefits to the widow for a period of one month or longer at the discretion of the committee. In a number of instances eligibility depends upon membership in the employees' benefit association.

Employees of the Interborough Rapid Transit Company, New York, who shall have attained the age of 70 years, provided they have been in the service not less than 25 years, are eligible to a pension. The plan also provides for pensions to employees with 25 years of service, regardless of age, who have become permanently disabled. The plan of the Omaha & Council Bluffs Street Railway, Omaha, Neb., provides arbitrarily for the retirement on pension of any employee 70 years of age who has been continuously employed for 20 years or more, but an employee with 20 years of service and 65 years of age may, at his option be retired. A disability clause also provides for the retirement of any employee with a service record of 20 years, provided disability is incurred while in the discharge of his duties.

The Washington Railway & Electric Company, Washington, D. C., divides its eligibles into five classes: (a) Employees 70 years of age, with 15 years of service; (b) employees over 55, with 15 years of service, who have become physically disqualified; (c) employees with

Digitized by Google

ANALYZED

15 years of service who have become physically disqualified by reason of injuries received in the discharge of their duties; (d) employees under 55, with 15 years of service, who have become disqualified may be granted limited pensions, within the discretion of the pension board; (e) employees with less than 15 years of continuous service who have become disqualified by reason of injuries received while in the discharge of their duties, for which they are neither wholly nor partially to blame, may be granted pensions for a limited period.

The Boston Elevated Railway is another property which classifies its pension eligibles into various grades, namely, all employees of an age of 65 years or more, with 20 years of service; employees aged from 60 to 64 with 25 years of service, and employees less than 60 years of age with 30 years or more of service. At the discretion of the pension committee and with the approval of the board of trustees, any employee with a 15-year service record who has become totally disabled as the result of accidental injury arising out of and in the course of employment by the company, may be granted a pension. It is further provided that employees with 20 years of service, regardless of age, may be retired if disabled as the result of sickness or injury.

Any employee of the Twin City Rapid Transit Company who has reached the age of 70 years, with 20 years of continuous service and who is a member of the employees' mutual benefit association, and whose salary has been $250 per month or less, is pensioned. Continuation in the service of employees past the age of 70 is subject to the approval of the medical director, department head and the president of the company. An employee who has reached the age of 60 years, whose salary and service render him eligible to a pension, may be pensioned at the option of the pension board. If incapacitated after 15 years of service, an employee is also eligible.

Key System Transit Company, Oakland, Cal., draws a line between employees who "may" and who "shall" be retired. All officers and employees who have attained the age of 70 years shall be retired; such of them as have a continuous service record of 20 years or more are entitled to pensions. Certain classes, including conductors and motormen, may be retired at 65 with pensions, if they have been 20 years or more in the service. Employees between 60 and 70, who have been 20 years or more in the service and who have become incapacitated and who cannot be transferred to other work which they are able to perform, may be retired and pensioned. The same rule applies to employees under 60, with service records of 25 or more years.

Effective Jan. 10, 1930, the Montreal Tramways Mutual Benefit Association, by a large majority of its membership, approved a resolution reducing the retirement age from 65 years to 60 years, at the same time raising the daily pension from $1.50 to $2. One of the most liberal of the plans is that of the Bangor Hydro-Electric Company, which provides for voluntary retirement with pension at age 65, and compulsory retirement with pension at age 70, in each case only 12 years of continuous service being required.

Ready to retire after a quarter century of faithful service. What provision has his company made for his future?

Eligibles under the retirement pension plan of the Georgia Power Company, are classified under four groups. Those who have been in the service more than 30 years and who are 60 or more years of age, are automatically retired with pension, unless they express a desire to continue in the service and are deemed capable of performing their duties. The other groups grade down to 15 years of service, regardless of age, where the employee has become permanently disabled in the course of his employment.

The plan of the Cumberland County Power & Light Company, Portland, Me., makes provision for the enforced retirement of men employees at the age of 65 and of women employees at the age of 60, unless for special reasons they desire to be continued in active service. This plan also provides that men may be retired at age 60 and women at age 55.

One large Southern property has no age retirement and does not pension employees on the basis of age alone, its present arrangement including only employees with 15-year service records who have become disabled. This same property, however, is now considering a general pension plan for taking care of aged employees.

Pensions are available to employees of a railway in the Mid-West after they have been continuously in the service of the company for 15 years. Retirement is optional at 60 years of age and compulsory at 70. Em-

Digitized by Google

ployees who have become totally and permanently incapacitated for further duty with the company, provided they have been in the service for 15 or more years continuously are entitled to a pension for a maximum period of 14½ years.

Many companies make provision for the eligibles to be continued in the service where they are physically able to perform their duties and choose to do so, rather than to retire. In some cases it is arranged to assign superannuated employees eligible to pensions to lighter tasks. Obviously, any arrangement which defers the day of retirement works to the advantage of the pension fund. Not only is the payment reduced but also the life expectancy over which pensions would have to be paid is shortened. The Montreal Tramways latest report shows 66 employees still on the payroll, each of whom had a service record of 35 years or longer. A considerable number of these have passed the retirement age of 60 years, but evidently prefer work at substantial wages to retirement on $2 per day.

It is provided in practically all of the plans now in effect that the pensioned employee may, at his option, engage in other work so long as it is not of a character detrimental to the company's interests.

Pension Rates Based on Previous Wages for Various Periods

General practice appears to favor basing the amount of the pension upon the average annual wages earned during the ten-year period prior to retirement, multiplied by the number of years of service. The amount is usually further fixed by maximum and minimum stipulations. An exception to this rule is the Montreal Tramways plan which provides a flat pension of $2 per day.

The pension plan of the Twin City Rapid Transit Company provides that any employee whose continuous service began prior to July 1, 1924, is entitled to a pension amounting to 2 per cent of his average monthly salary during the last ten years of service, multiplied by the number of years of continuous service, but in no event more than $50 per month, provided his salary or wage has been $175 per month or less. An employee receiving an average wage of from $175 to $250 per month may receive a pension not to exceed $60 per month. Employees beginning their continuous service subsequent to July 1, 1924, may receive 1.5 per cent of their average monthly wage the last ten years, but such monthly pension may not exceed the following: $40, if the average ten-year salary is $150 per month or less; $50, if the average ten-year salary is $151 to $175 per month; $60, if the average ten-year salary is $176 to $250 per month.

The Omaha & Council Bluffs Street Railway has a plan which provides for conductors and motormen a pension of $1 per month for each year of continuous service, with no pension exceeding $30 per month. Other employees eligible to pension are retired on an allowance based upon 1.25 per cent of the annual wages received at the time of retirement, multiplied by the number of years of continuous service; but no pension shall equal more than 35 per cent of such employee's salary or wages received at the time of retirement, and in no event shall it exceed $500 per annum; neither shall any pension be less than $20 per month. The plan of the Interborough Rapid Transit Company, New York, provides for pension allowances upon the following basis: For each year of service 1 per cent of the average monthly wages based on the rate of pay for the ten years next preceding retirement, provided that in no case shall the aggregate pension allowance be less than $20 per month.

Pensions of the Bangor Hydro-Electric Company are computed upon the basis of 1.5 per cent of the average monthly pay received during the last ten years before retirement, multiplied by the number of years of service. The minimum pension is $15 per month.

The Boston Elevated Railway has had a pension plan in effect since 1920. In the intervening years several changes have been made in the provisions of the plan, but the present arrangement provides that the amount of the pension shall equal 1 per cent of the average yearly earnings for the ten years prior to retirement, times the number of years continuously employed, but such pensions shall not be more than $2,000 per year nor less than $375 per year.

Pension allowances authorized by the Washington Railway & Electric Company are fixed upon the following basis: If the service has been continuous for 15 and less than 20 years, 20 per cent per annum, in equal monthly installments, of the average annual wages for the ten years next previous to retirement; if the service has been continuous for 20 and less than 25 years, 25 per cent of the average annual wages for the ten years next previous to retirement; if the service in the company's employ shall have been continuous for 25 years, 30 per cent per annum of the average annual wages for the ten years next previous to retirement; if the continuous service exceeds 25 years, then for each year in excess thereof there shall be allowed an additional 2 per cent of the average annual wages for the ten years next previous to retirement. It is provided, however, that the pension allowance to any employee shall be not less than $20 per month nor more than $50 per month. There is further provided a funeral allowance of $100 to be paid upon the death of any employee on the pension roll.

Wide discretionary powers are vested in the pension board of the Key System Transit Company, Oakland, Cal., by a clause which provides that "for exceptionally long and unbroken service, with first-class record, or for other good and sufficient reasons apparent to the board of directors, upon recommendation of the board of pensions, the board of directors may, at its discretion, place any officer or employee on the pension list and fix a pension or pensions at such an amount as may in the judgment of the board of directors be equitable and appropriate." The regular pension allowances of this company, however, are authorized upon the following basis: For each year of service, an allowance of 1.5 per cent of the first $50 of the highest average monthly pay of the officer or employee during any consecutive ten years of service, and in addition, 1 per cent of any excess of such highest average monthly pay over $50; provided, however, that in no case shall the allowance made be less than $20 nor more than $75 per month.

The plan of the Georgia Power Company contains a clause providing that "all annuities shall be based on the gross earnings of employees during the 12 months next preceding their retirement."

The amount of each pension is based upon a combination of age and years of service, under four classifications. Those 60 years old, with 30 years or more of service receive a yearly sum equivalent to 30 per cent of the gross earnings, as set forth above. Those with service records of 25 years and not more than 30 years, receive 27.5 per cent, while those with service records of between 20 and 25 years, and who have reached the age of 60, receive 25 per cent of the last twelve months earn-

Digitized by Google

ings. Total disability, following 15 years of service, regardless of age, entitles the employee to a pension based upon 25 per cent of his last year's wages.

Retirement annuities of the Cumberland County Power & Light Company range from 1.5 per cent to 2 per cent of the average annual salary of the employee for the period of continuous service, times the number of years of service, but not exceeding 50 per cent of the final annual salary nor shall the amount exceed $6,000 per year.

Payments Made From Current Earnings

Few of the properties reporting have set up an adequate reserve to meet future or accrued liabilities. The usual method followed is to make payments from current earnings. A notable exception is the Montreal Tramways, whose plan, based upon well-considered principles, has permitted the accumulation of a reserve of more than $540,000. Following an analysis of its plan in 1923 the Twin City Rapid Transit Company began to deposit to the credit of its pension fund $10,000 per month. At the present time payments are aggregating about $50,000 per year, and the company's reserve as of July 1, 1930, has reached $608,159.32. Another large company inaugurated its pension plan in 1910 by setting aside 0.25 per cent of its gross receipts to meet contingencies. A reserve of approximately $50,000 has been accumulated during the intervening years, but at the present time pension disbursements are taking practically all of the regular allotment and no additions are being made to the reserve. One of the most recent plans, that of the Cumberland County Power & Light Company, makes provision for setting aside 1 per cent of the annual payroll from which to meet future retirement pensions.

"Under the terms of our agreement with our employees' mutual benefit association," writes a Mid-West executive, "the company sets aside 1 per cent of its operating revenues to cover relief work and pensions. The balance available after current payments on these accounts is turned over to a trustee to be credited to the pension fund, but in no event is the amount so created to be less than 0.5 per cent of the company's operating revenues in any one year. The employees themselves make no contribution to the pension fund."

With a few notable exceptions none of the plans examined provide for contributions from employees, although several properties maintain benefit associations or even life insurance plans in which employees participate through regular deductions from their wages. Members of the Montreal Tramways association are charged an admission fee of $1, and pay monthly dues of $3. This sum, however, covers much more than the pension, as the association pays its members sick and disability benefits, as well as permanent disability benefits, provides medical and pharmaceutical attention and pays the premium to an outside company on group insurance to the amount of $1,000 on each member.

The Washington Railway Relief Association, maintained and supported by employees of the Washington Railway & Electric Company, provides, among other things, for sick benefits, life insurance and a pension of $30 per month to each member who receives a pension from the company. There is, however, no connection between this pension and that of the company, so the plan cannot be strictly classified as a contributory one.

While few of the properties providing pensions appear to have sought actuarial advice when the plans were inaugurated, a number have since done so and others are contemplating early action in this direction. When the Montreal plan was first organized a competent actuary analyzed it and decided that the association could be successfully conducted along the lines proposed.

One large operating company states: "We have had actuarial computations which show that in the course of years the monthly payment will be extremely high." Another company writes, "When these two plans (pension and group insurance) were put into operation it was forecast that the maximum liability would be reached in five to six years, but this was not the case. In 1929 a detailed study was made of the future liability, and it was estimated that the costs would be 40 per cent greater in ten years than at the present time." One property which has gone into the matter very thoroughly was told by actuaries that $2,250,000 should be invested to guarantee payment of future pensions. Another estimates its pension liability at $500,000.

The Montreal Tramways, which has always supported its employees' mutual association most generously, appropriated for this purpose $158,721.26 in 1929, an increase of $16,260.85 over the 1928 allowance. Union Street Railway reports that 0.68 per cent of the total payroll was required to meet pension payments between 1925 and 1929. It is estimated that 1930 payments will require 1.13 per cent of the company's gross revenues. Another property is at the present time paying out in pensions between $5,000 and $6,000 per month. The Interborough Rapid Transit Company provides for its pensions out of a company donation of "not to exceed $50,000 per year." The Twin City Rapid Transit Company sets aside $10,000 each month for this purpose. The present annual cost of the Omaha & Council Bluffs Street Railway pension plan is estimated at $24,000.

Obligations Become Larger than Original Estimates

From the tenor of the replies received in the Journal survey it is quite apparent that a number of the companies which have adopted pension plans are experiencing difficulty in meeting their growing obligations, while others anticipate difficulty in the future. One company has already announced that, while present pensioners will be taken care of so long as it is possible to do so, no further pensions will be granted until the company's financial position is improved. Another property, in the hands of a receiver, anticipates difficulties at an early date.

The Washington Railway & Electric Company writes: "The number of pensioned employees and the amount of their payroll is at present in excess of the original figures planned by our management, and as time goes on it will undoubtedly be necessary to make some changes in our present system in order to provide for the gradually increasing number of pensioners." A company which, in addition to supporting a pension plan, also carries group insurance for its employees writes: "Our payments for 1929 were much in excess of the maximum estimate when these forms of gratuity were adopted." This company rewrote its entire plan quite recently. Existing pensions will be carried on as heretofore, but the pensions of employees who retire in the future will be considerably reduced below the former figure. Even so, the mounting costs of this form of relief are causing the management serious concern. The Boston Elevated Railway has been obliged to reduce its pension allowance 1 per cent, effective Sept. 1, 1929.

"On account of the average age of our employees I

Digitized by Google

expect that the pension obligations will become very heavy as time goes on," writes C. C. Vargas, Key System Transit Company, while another manager states that although no present difficulty is anticipated he is concerned as to the future and proposes to have an actuarial analysis made. The Georgia Power Company views the future with some uncertainty, in the belief that the present setup holds the possibility of difficulties later on.

"Ours is a joint utility, doing both an electric railway and an electric power business," writes one executive, whose company is setting aside 1 per cent of its operating revenues to meet pension and relief payments. "In the electric utility, which is the fastest growing service, the quantity of labor required per dollar of operating revenue is materially less than in the railway department. The faster growth of the electric business is, therefore, continuously operating in our favor. With the railway utility alone we are quite sure that our present reserve provisions would prove inadequate. The net result has probably been to gradually strengthen the position of the reserve, and while we are not certain of the present adequacy of our reserve fund, we feel that its position is steadily being improved. Certainly, we are in no serious or immediate danger."

With few exceptions the present plans are not definitely contractual. Protective clauses usually provide that the amount and terms of the pensions may be changed or discontinued at the discretion of the management. A typical protective clause provides as follows: "Whenever it shall be found that the basis of pension payments herein provided shall, in the judgment of the president of the company, create demands in excess of the company's revenues available for pension payments, a new basis ratably reducing existing and future pension payments shall be established." Another plan stipulates that "the foregoing provisions for pensioning aged and injured employees are and are to be accepted as purely voluntary and gratuitous, and as imposing no contractual or other obligations upon the part of said companies to continue the same, either as a whole or in any individual case or cases, or to deny to said company the right to withdraw from the same, or to discontinue the said pension, or any individual pension thereunder, if at any time, in their own judgment and discretion, it shall be expedient or desirable to do so, in which event all or any pensions allowed thereunder shall forthwith cease."

The pension plan of the Interborough Rapid Transit Company contains the following clause: "Whenever it shall be found that the pension allowances shall create demands in excess of the annual appropriation ($50,000), and as often as such conditions shall arise, a new basis ratably reducing the pension allowance shall be established to bring the expenditures within the limit of the fund, and the decision of the board of directors in establishing such a basis shall be absolutely conclusive." The Boston Elevated Railway reserves the right to reduce all pensions pro rata so that the entire expenditures for pensions during any year shall not exceed 2 per cent of the salaries and payroll for that year. The Omaha & Council Bluffs Railway plan contains a section which states: "The establishment of this pension system by the company is purely voluntary and gratuitous . . . and the company hereby reserves the right to alter or abolish the pension system and all allowances under it. . . ."

The plan of the Georgia Power Company expressly states that "the company reserves the right to discontinue any and all annuities or any part thereof at any time." The company further reserves the right to withdraw or discontinue all annuities theretofore granted and then being paid, and to alter or amend the plan as necessity may dictate.

Anticipating possible future pension legislation the Cumberland County Power & Light Company stipulates that "in case any benefit, annuity or pension shall be payable by the company under the laws now in force, or hereafter enacted, in any state or county, . . . the excess only, if any, of the amount prescribed in this plan above the amount of such benefit, annuity or pension prescribed by law, shall be the benefit or annuity payable under this plan." The company's board of directors is further authorized under the plan to "annul, alter, add to, or amend, any and all provisions contained in this resolution."

"The establishment of this pension system," reads a clause in the plan of the Bangor Hydro-Electric Company, "is intended only to declare the present policy of this company and to give authority and instructions to the officers of the company to carry out this policy, and neither the establishment of the system nor the granting of the pension, nor any action now or hereafter taken by the pension board or officers of this company shall be held or construed to create a contract." It is further provided that "the company hereby expressly reserves the right . . . to terminate the pension system or any pension or pensions previously allowed, or to modify the pension system in any respect either generally or in its application to any specific case."

Contributory Support Desirable

Few of the pension plans now in effect require any contributory support from the employees themselves, although a number of executives replying to the Journal's inquiry expressed themselves in favor of some such arrangement. For example, one executive writes: "From our experience, I do not believe a company itself should attempt to carry a pension plan; it should be taken out with one of the established life insurance companies. A pension plan, in effect, is for the purpose of creating an estate for an employee in his old age from which he may derive an income. If his savings plus a similar contribution on the part of the company could be held over a term of years until he comes to the retirement age and then distributed to him with interest over the remainder of his life, it would have the same effect as a pension plan and might have some better features. I feel that our men would appreciate a pension plan more if they were to contribute to a portion of it."

"I believe that the employees should contribute to this future annuity," writes a general manager whose company has a successful plan in operation, "and that the employer should charge against each year's operations the present value of his future pension liability accruing on account of employment during any year. I further believe that the employers' and the employees' contributions should be deposited with some outside trustee."

"I am strongly convinced that the employee should pay something toward his pension," writes an executive whose company has supported a pension plan for the past sixteen years. "In the first place," he continues, "one is not so apt to appreciate something for nothing as he would something to which he had personally contributed. In the second place, it is an increasingly heavy drain on any company to carry its pension costs unaided, especially where there is a very small labor turnover. More and more men are growing old in the service and will ultimately be candidates for pensions."

Group participating in track foremen's training classes conducted by the Cleveland Railway

SELLING AN IDEA
to the Foreman

"IF YOU were asked who is the key man constituting the bridge between capital and labor, between executives and wage earners, what would be your reply? Mine would be the foreman. The influence, the importance of the foreman is but poorly understood by many employers. Correcting this defect would mean much for the furtherance of better relations between employers and employed and of national stability. American foremen, collectively, have more to do with molding sentiments among the rank and file of the people and families of this country than politicians, editorial writers, preachers, teachers, or labor union leaders, or any other class. Training schools for foremen should constitute an outstanding feature of American industrial and economic life."

—B. C. FORBES, EDITOR *Forbes' Magazine quoted from the Cleveland News*

By HOWARD H. GEORGE
Superintendent of Way Cleveland Railway
Cleveland, Ohio

In the belief that standardization of track construction and maintenance methods can best be brought about by uniformity of instruction, the Cleveland Railway has conducted a foremen's training course which has produced excellent results.

ON THIS very important subject the writer is in full accord with Mr. Forbes. Many track operations today require more than ordinary skill and training for which the run of common labor is not fitted. Because of the conditions which exist in the field from which our labor must be recruited, it is doubly important that the work be in the charge of a competent foreman and that each foreman be thoroughly instructed as to what is expected of him.

In order to put this theory into practice, there was organized, during the past winter, in the Way Department of the Cleveland Railway, a track foremen's training class. The membership in this class comprised all division foremen and general foremen, together with a selected group of foremen and sub-foremen, whom we had reason to believe would develop, in such a school, into suitable foreman material. Classes were held one evening each week during the first three months of the year, and attendance was compulsory for the division foremen and general foremen, but optional with the others.

A regular series of talks was mapped out in advance covering all the more important phases of track construction and maintenance operations. These talks were mimeographed and, at the close of each class, a copy

Code of Ethics for Foremen

CLEVELAND RAILWAY—WAY DEPARTMENT

[1]

The foreman should regard his profession as a field of social service offering an opportunity to help working people obtain maximum satisfaction from life.

[2]

The foreman should endeavor to earn, and guard carefully, a reputation for good moral character, good citizenship and common honesty, and to support and promote the uplifting influences of the community.

[3]

The foreman should recognize that every man above, beside, or below has an inherent desire to do good work and to be a useful and respected citizen. He should not assume that any man wants to do anything less than his best until he has considered every other possible motive.

[4]

The foreman should keep an open mind on all subjects, striving to maintain a broad and balanced outlook, and being always willing to recognize merit in another's ideas.

[5]

The foreman should deal fairly with the management, the men and other foremen, assuming responsibility for his own mistakes and refraining from shifting blame to others.

[6]

The foreman should strive to understand the principles of business which make for success or failure of industry. He should pass at least some of the fundamentals of business principles along to his men, so they can see their own relation to the general scheme.

[7]

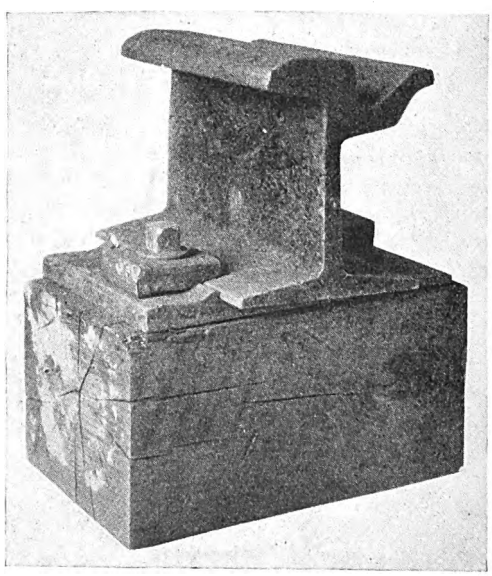
The foreman should keep informed as to the latest developments in equipment and processes. He should recommend, or put into effect, such methods as will produce improved quality, lower costs for the product, and better working conditions.

was given to each member present. Each lecture was informal but covered the same field as the printed copy which the men afterwards received, so that they had it available for reading and study during the ensuing week. The talks were illustrated with blackboard sketches, models and large scale blue prints.

The first half hour of each evening was devoted to a written examination covering the subject of the preceding week. The next three-quarters of an hour were devoted to the subject for the evening. There followed fifteen minutes for reading to the class the correct answers to the questions covered by the quiz of the evening, and the last fifteen minutes were devoted to general questions and answers.

Perhaps some of you will say "Maybe George can do it, but if all his track foremen can read and write, he is more fortunately situated than I am." My answer is that our situation in this respect is actually no different from that which probably exists on any other property of our size. Out of the total registration of 45 in the class which we conducted, ten were of general supervisory grade and were not required to take the written examination. The men, however, were required to attend class and assist in the conduct of the examinations, as will be explained more fully later. Of the remaining 35 who took the examinations, nineteen were unable to read or write although, in every case, they had been track foremen or sub-foremen for many years. Most of the men who could not read or write were Italians. Where the men were unable to read for themselves, they arranged to have some one read the various lectures to them during the week. Usually this was done by one of the older children in their own family who had the advantage of at least a grammar school and frequently a high school education.

In the written quizzes, we assigned one of our supervisory force or some one from our engineering department to sit with each man who was unable to write. These helpers read and explained the questions and put down the student's answers in as nearly their own language as possible. Each question was given a rating, based upon a total mark of 100. In no case did spelling, grammar, punctuation or penmanship play any part in the grading of the answers. We were entirely satisfied if the answer convinced us that the man knew what the correct answer was in each case.



Model of grooved girder rail and tie assembly, with screw spikes and clips, used in demonstration before foremen's training group

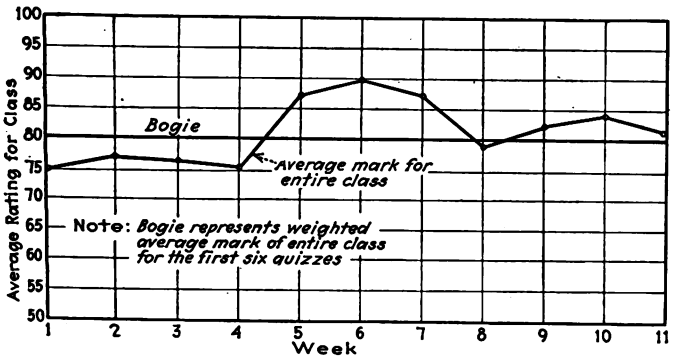
At the opening of the course, each member was furnished a copy of the small printed booklet prepared by Howard J. Montgomery, Chicago, entitled "If I Were a Foreman." This booklet, while necessarily containing some reflections which do not apply to the track foreman, certainly does contain many observations which fit his case admirably, and if the track foreman will study them and apply as many as possible to his own case, he cannot help but increase his value to his employer and raise himself in the estimation of those directly under his control as well. In addition, we furnished each man in the class with a copy of the Code of Ethics for Foremen, which was prepared by a committee of the National Association of Foremen.

Digitized by Google

The subjects scheduled for discussion at the various classes were as follows:

Purpose of Course and General Duties of Track Foreman.
Subgrade, Drainage and Ballast.
Ties.
Rails and Rail Joints.
Miscellaneous Rail Fastenings.
Track-laying and Surfacing.
Pavement and Its Foundation.
Welding and Grinding Rails and Joints.
Track Tools and Equipment.
Track and Pavement Maintenance Practices.
Safety First Talk on Accident Prevention.
Review and Track Construction Moving Pictures.

When the classes were announced, we were flooded with requests to be allowed to attend, and could easily have formed three classes had membership been thrown open to all applicants. In order to ascertain how much of the interest was real and how much was forced, we extended to any one in the class the privilege of dropping out after the fourth session, but only one man took advantage of the opportunity. The men were willing and



Progress made by Cleveland track foremen's class, as indicated by average rating of all quiz papers submitted. The heavy horizontal line represents the bogie, determined by calculating the weighted average rating of the class for the first six quizzes

anxious to learn and displayed a disposition to work hard and acquire what knowledge we were trying to teach them.

There was, at first, a feeling among a number of the men that they were being examined for the purpose of determining whether or not they were to be retained in the service or discharged, and there was, as a consequence, some uneasiness on this score. We were soon able, however, to reassure every man on this score by making it clear that we had but two objects in view in organizing the class. The first was to help the men increase their own knowledge of the business, and to enable us to become more familiar with their individual qualifications. The second was that, through the course, the Cleveland Railway would benefit by reason of better supervision of its track work, with a resulting higher standard of construction and consequent longer life of its track structure.

What we are trying to do is to give every foreman the same kind of instruction, to the end that our work may be more uniformly done. We are striving to impress upon the mind of each man the important relation between the care which is given the various details of construction and the life of the structure. The only practical way this can be accomplished is by getting the men together in a class.

Just how much we will be able to accomplish, as compared with the goal towards which we are striving, remains to be seen. Judging, however, from the interest which every man in our last winter's classes displayed, and from the intelligent questions which were asked in open class, there is no doubt regarding the outcome, and we will undoubtedly make this class an annual affair. It is even possible that the course will be split into two classes, one for the more advanced men, the other for the more backward. Suffice it to say that the results obtained thus far have fully justified our expectations.

Effective Sales Promotion Work by Trainmen at Norfolk

By F. C. Womack

Manager of Transportation Norfolk Division
Virginia Electric & Power Company

SALES promotion of street car and bus transportation is the only solution for the gradual yearly falling off in gross revenue that is now so threatening a menace to the very life of the industry. Definitely committed to this policy, the Norfolk division of the Virginia Electric & Power Company is preparing to launch an intensive campaign of transportation sales promotion in Norfolk which is in line with like campaigns to be inaugurated in the other divisions of the Virginia Electric & Power Company in Richmond, Portsmouth and Petersburg.

With the steadily increasing popularity of the automobile, there has been a corresponding decrease year by year in the gross revenue to transportation companies throughout the country for street car and bus transportation. This decline, which during the past five years has varied between one and five per cent annually, presents a grave emergency which transportation companies must meet and overcome if they are to continue to furnish reasonably good service.

During this same period, realizing that the emergency must be met, transportation companies have concentrated their efforts toward reducing the cost of operation and at the same time increasing efficiency. In this they have, as a rule, been remarkably successful. Under the principle of mass purchasing and other modern methods, the companies have been able during this period to greatly increase efficiency, replace old with modern equipment, speed up schedules and, at the same time, pay a higher wage to the operator—all at a decreased yearly cost of operation.

This decrease in the cost of operation, to some extent, has acted as a sort of financial buffer to take up the shock of the gradual falling off in gross revenue. The situation has now reached the place, however, where the cost of operation has been cut to the bone, and still there is no letting up in that gradual falling off in gross revenue. The one solution which will solve the problem is the "selling" of bus and street car transportation to the public.

The main cog in the operation of this sales promotion machinery is the operator of the street car or bus. Through our experience in accident prevention contests, we have found that the men who operate our street cars and buses are always ready and willing to stand four-square behind whatever move for the betterment of the company in which the officials show a real interest. Convinced that the officials were vitally interested in the reduction of accidents, the Norfolk division during March reduced the number of accidents to less than 50 per cent

Digitized by Google

of the number for the same month a year ago. Last year the total number of accidents in the Norfolk division was 273. This year it has been reduced to 127. One of the main factors in this reduction was the fact that the men at the controls of the street cars and buses, realizing that the heads of the company were vitally interested in reducing accidents, became imbued with the same interest.

A similar result can be achieved when the operators realize that the heads of the company are vitally interested in increasing the number of customers. Once we can get the operators to look upon every pedestrian and every person they see in a private automobile as a potential customer to be treated as such, much will have been accomplished toward selling street car and bus transportation to the public.

But this is only the first step in sales promotion. Following close behind this there must be a concentrated effort toward educating the public away from the single cash fare. In every instance possible an effort will be made to sell the customer tokens or a weekly pass. One of the characteristics of the American people is that they are inclined to use what they have. Sell a man six cigars and he will smoke twice as much as he would if he bought these cigars one at a time. Sell him a block of theater tickets good any time during a period of six months and he will use them up in the first six weeks. The same is true of street car and bus transportation. Half a dozen tokens sold at one time mean that the customer will ride just about twice as often as he would upon a cash fare basis.

As a final link in the sales promotion activities of the Virginia Electric & Power Company, a group of highly intelligent salesmen will be employed to carry the message of street car and bus transportation direct to the potential customer. To those people living along the suburban lines who have been accustomed to depend upon their own automobiles in most instances and who use the street cars and buses infrequently, the railway will appeal upon the basis of economy, showing them in actual dollars and cents that we can carry them to and from their places of business at a saving. At the same time we are committed to a program of speeding up these suburban lines and maintaining thereon regular schedules of operation that can be depended on. We expect the going to be hard in these sections at first but in the end, we feel certain we will be able to greatly increase business along these suburban lines.

It is an entirely different story with the car owner living in those districts where frequent and steady schedules are maintained and it is upon this type of potential customer that the transportation salesmen will concentrate their activities. In every city there are literally thousands of car owners—merchants, professional men, clerks, salesmen, men in practically every walk of life—whose daily activities are confined to a single office building or store in the business district. For month after month and year after year these men have been using their private automobiles as a means of transportation to and from work all unmindful of the fact that the power company maintains bus and street car service in their district that offers transportation that is not only cheaper but faster than their own cars. It is this type of citizen who must be sold upon bus and street car transportation if the steady decline in gross revenue from this source is to be checked.

Selling of this transportation is to be no hit or miss proposition. There will be no dealing in generalities when our salesmen approach these prospects. Each man's individual case will be surveyed and studied for weeks in advance before the salesman calls upon him. As a result, the transportation salesman will have concrete facts to work upon when he goes in to sing the praises of street car or bus transportation.

These data are to be obtained first through a study of the automobile license numbers in the different parking stations in the business district and along those streets where parking throughout the day is permitted. Through a follow up system the names of these different car owners will be secured and then for several days the movement of each car will be studied. Distance between the parking station and the place where the owner is employed will be computed, driving hazards will be determined, the cost of parking will be determined and a check of the actual weekly mileage in driving between home and work will be computed.

Once these data have been compiled—and they will be comparatively easily secured—the transportation salesman will call upon the prospect armed with information which will prove conclusively that the bus and the street car offer him quicker, safer and cheaper transportation day after day, week after week, and year after year between home and work. We believe that this campaign will prove effective. We believe, also, that it is the only manner by which this steady decline in gross revenue from bus and street car transportation can be stopped.

London "Tube" Extensions to Cost $65,000,000

CONTRACTS amounting to approximately $65,000,000 are about to be placed by the London Underground group of railways for extensions and reconstructions on the Piccadilly line. Two extensions are to be started, one to the north from Finsbury Park to Cockfosters, at a cost of $25,000,000, the other west from Hammersmith to Northfields, at a cost of $17,500,000. The balance of the $65,000,000 is to be spent on reconstructing existing stations.

The whole of this work will be carried on simultaneously, and will give employment, when in full swing, to more than 20,000 men. It is hoped to complete both extensions and reconstructions in from 2½ to three years.

This concentrated effort, the largest ever embarked upon by the Underground group in so short a space as three years, has been rendered necessary by the phenomenal growth of London traffic in post-war years.

Work on the Cockfosters extension is expected to commence on Sept. 1 and to occupy two years to complete, but as soon as the line has been carried as far as Arnos Grove, roughly one-half the total distance of 7½ miles of track, it will be opened to the public.

The construction work will involve tunnelling from Finsbury Park nearly to Arnos Grove. There the line will come out into the open, and will be carried across Arnos Park by a viaduct, to disappear into a tunnel on the north side, where the land rises considerably, coming into the open again at Chase side. Thus in the 7½ miles there will be 4 miles of tunnel.

The western extension to Northfields will follow the line of the District Railway. It will be above ground all the way.

Leicester Square is to be made into a subsurface station. It will be a second Piccadilly Circus, but on a

Digitized by Google

smaller scale, with one set of escalators connecting direct with the platforms. Four entrances will be provided to the booking halls from the pavement level, one at the Hippodrome Corner, another at Wyndham's Theater Corner, and two just north of the present station on either side of Charing Cross Road.

In the reconstruction of Dover Street station the existing entrance will be abolished. Two new entrances provided, one on the south side of Piccadilly, close to the Ritz Hotel and the entrance to Green Park, and the other on the north side near Devonshire House. These will lead by escalators to the platforms.

Similarly, at Hyde Park Corner, entrances are to be made to the station from both sides of the thoroughfare, so that it will be possible to walk by a subway under the road between St. George's Hospital and the Park.

At Knightsbridge the alterations contemplate the construction of new entrances at the top of Sloane Street to the east and at the corner of Hans Crescent to the west.

Another improvement is the provision of interchange facilities between the British Museum Station, on the Central London Railway, and Holborn Station, on the Piccadilly line.

International Tramway and Bus Association Holds Biennial Meeting at Warsaw

EUROPEAN transportation men found much of interest at the 22nd convention of the Union Internationale de Tramways, de Chemins de Fer d'Intérêt Local et de Transports Publics Automobiles (International Tramway and Bus Association) which was held at Warsaw, Poland, from June 29 to July 2.

The convention opened informally with a reception at the Polish National Club on Sunday evening, while the official opening was held the next morning in the salon of the Warsaw City Hall. The meetings were presided over by F. de Lancker, managing director of the Brussels Tramways, who is president of the association. Addresses were made by Alphonse de Kühn, minister of communications in Poland; Mr. Szpotanski, vice-president of the Municipal Council of Warsaw, and Mr. Budkiewicz, president of the Polish Union of Means of Transport. In these addresses, the history of Poland since the war was outlined, with particular reference to the plans for modernizing the country's transportation systems.

Technical sessions were held on Monday, Tuesday and Wednesday, both morning and afternoon. A number of papers on a wide range of topics were presented. A paper was read by E. Jayot, director general of extensions, Perfecture of the Department of the Seine, on the comparison of subways and surface lines. Dr. Wilhelm Pforr, general manager of the Berlin Transportation Company, presented a paper on braking tests, following up the work that was done by the committee reporting to the Rome convention two years ago.

At the Monday afternoon session was presented a report prepared by M. H. Coens, chief of substations and distribution of the Brussels Tramways and A. Allard, chief engineer of the Suburban Railways of Brussels, on the subjects of energy distribution for tramways and comparison between systems of conversion from high-tension alternating current to low-tension direct current. Another report presented was prepared by Gaetano d'Alo, traffic engineer of Milan, Italy, on the track structure. A paper was read by P. Lo Balbo, research director of the Piedmont, Italy, tramways, on storage battery vehicles for rail service in Europe.

Two sessions were held on Tuesday, at which numerous reports were given. Dr. Philip Kremer, manager of the Frankfort a.M. Tramways, prepared a report on improvements in rolling stock for railways and road transport with respect to the comfort of passengers, facilities for service and improvement of operation. This report was a comprehensive review of recent European practice in car and bus design. H. Arnold, general manager, and F. Eichelhardt, chief engineer, both of the Vestischen Railway, Herten, Germany, reported on the use of internal combustion motors burning light oils for rail service. R. Podoski, professor of engineering at the Warsaw Polytechnic School, presented a paper on studies of electrolytic corrosion.

A report on the comparison of systems of co-ordinated transport including tramways, rapid transit lines and buses, was prepared by M. Nestrypke. A paper was read by M. Lange on automatic block signals for single track. Another paper was by L. Sekutowicz, Paris, on the use of light-weight metals in overhead line construction.

Wednesday's session opened with a discussion of the report by H. Werner, vice-director of the Vienna, Austria, tramways, on the development of electric equipment of rolling stock. This report was principally a tabulation of answers to a questionnaire relative to the design features of recent types of propulsion motors, especially those with high-speed armatures developed for the new types of drive. The last paper was that of L. Bacqueyrisse, general manager in charge of operation and technical service of the Société des Transports en Commun de la Region Parisienne, which operates all the transports in Paris, on methods of facilitating the use of the service by passengers on buses, tramways and rapid transit.

At the concluding session President de Lancker summed up the discussion which was held on the various papers and reports. It was decided to continue the preparation of information on the same subjects, to be presented at the next convention, which will be held at the Hague in 1932. Much interest was shown in regeneration of electric energy, and it is planned to make a special report on this subject. A special meeting probably will be held in Paris next October to witness tests of three cars fitted with regenerative equipment.

Following the meeting trips in Poland were taken by three groups of delegates. One of these was to the cities of Krakow and Katowice in Southern Poland, where many of the manufacturing plants are located. The three groups joined at Poznan on July 5 to assist in the formal opening of the International Exhibition of Transport and Touring being held in that city this summer.

This 85-ton locomotive has been built for service on 1,500 volts and 600 volts, both trolley and third rail

Double-Voltage Operation Features Midland Utilities Locomotive

Service can be given on 1,500 or 600-volt lines on its several subsidiary railways by changes of circuits and minor adjustments

By T. F. Perkinson
Transportation Engineering Department
General Electric Company

TWO 85-ton direct current electric locomotives with novel features have been obtained by the Midland Utilities Company of Indiana for service on its various associated lines. During certain portions of the year they will be assigned to the 1,500-volt Chicago, South Shore & South Bend Railroad. At other times, when traffic demands require, they will be assigned to 600-volt associated properties, such as the Aurora, Elgin & Chicago Railroad, and the Chicago, North Shore & Milwaukee Railroad. These locomotives, constructed by the General Electric Company, are arranged for easy change-over of control circuits, auxiliary apparatus, etc., so that operation under a 1,500-volt or a 600-volt d.c. contact line or with a 600-volt third rail can be successfully undertaken.

Mechanically the locomotives are of the non-articulated double-truck type. The center plate of each truck is floating, supported by two transverse semi-elliptic springs suspended from the truck transom by centering hanger links. The transom casting is bolted to steel side frames which carry the pedestal jaws. The side equalizers are unusual, each being formed by two irregularly shaped forged steel plate bars. Two heavy coiled springs rest in cast pockets supported by the two plates forming the equalizer bar and carry the weight of the side frames with their superimposed loads. The wheels are 42-in., A.R.A. standard, with 3½-in. steel tires. The truck brake work is of the spreader type and is actuated by two cylinders, one mounted on each side of the truck frame. The Miner friction draft gear is used and couplers are of the standard A.R.A. type with 6x8-in. shank.

The cab superstructure is of the modified steeple type. The main cab has two operating compartments and an apparatus compartment with passageways on each side. All necessary control apparatus is in duplicate. Each operating cab has 4 kw. of electric heaters.

The center compartment contains the contactors, reverser, resistors, switches, control motor-generator set, etc., necessary for control of the traction motors. Access is obtained through a door from one of the operating compartments. The lower portion of the sides are covered with wire screening, giving a clear view of the apparatus and eliminating the danger of accidental contact with it. The top section of the compartment, containing the accelerating grids, has four transverse ventilators welded to the cab roof, giving natural circulation of air. Each auxiliary end cab houses an air compressor and a propulsion motor-blower set so located that a short

Digitized by Google

direct path from the fan outlet into the longitudinal air duct is secured.

Four GE-704 d.c. series motors for 750 volts drive the wheels through single reduction gearing. These motors are of the box-frame, nose-suspended, forced-ventilated, commutating-pole type insulated for 1,500 volts. Air from the ventilating duct is led to each motor through an all-metal duct arranged to permit swiveling of the trucks. The air is taken in to the motor through an opening in the frame located above the commutator and passes out through protected openings at the pinion end.

The motor armature bearings and axle suspension bearings are of the waste-packed constant oil-level type.

The gears and pinions are of high-carbon steel, heat treated, and forged from solid steel blanks. The gears are of the non-resonant type,ringing being practically eliminated by the use of lubricant retaining rings inside the gear ring on either side of the web.

The control equipment is of the non-automatic electro-pneumatic type, arranged for multiple-unit operation. There are two motor combinations available for each direction of motion on either 600 or 1,500 volts. The first or low-speed combination has eight resistance steps, one full-field running step and one reduced field running step. The second or high-speed combination has seven resistance steps, one full field running step and one reduced field running step. The two groups of two motors each are connected in series on 1,500 volts, and in parallel on 750 or on 600 volts. The first combination connects two groups of motors in series, and the second connects them in parallel.

Principal Data of Double-Voltage Locomotives

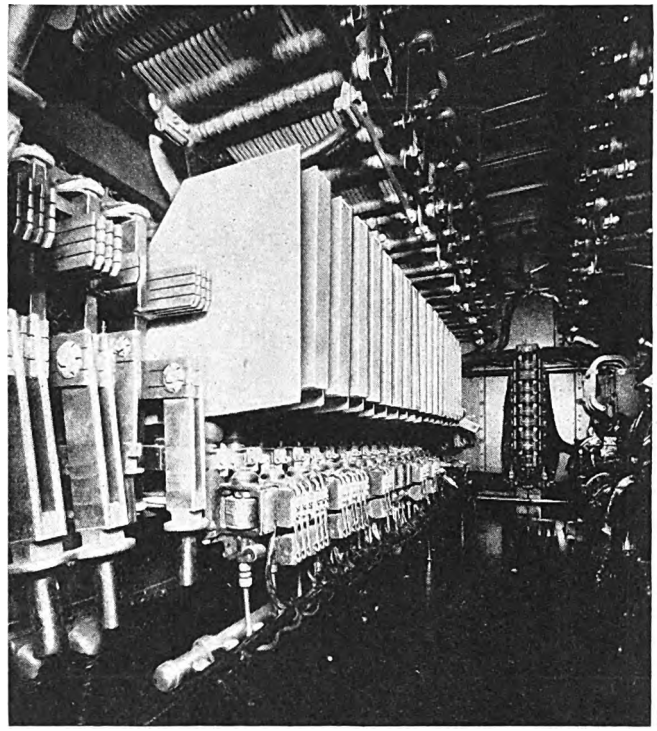
Class of service	Freight and switching
Trolley voltage	1,500 or 600
Driving wheels, number	8
Driving wheels, diameter, in	42
Total weight, lb	170,000
Weight on driver, lb	170,000
Weight per axle, lb	42,500
Weight electrical equipment, lb	57,600
Weight air brake, lb	5,400
Weight mechanical equipment, lb	107,000
Length over knuckles	39 ft. 1½ in.
Width over arm rests	11 ft. 1½ in.
Height, trolleys locked down	14 ft. 0 in.
Total wheel base	27 ft. 0 in.
Rigid wheel base	8 ft. 8 in.
Type of control	PCL, multiple unit
Motors, number and type	Four GE-704-A-1
Gear ratio	71/18
*Continuous tractive effort, lb	16,800
*Continuous speed m.p.h.	26.7
*Continuous current rating, amp.	650
*Continuous output, hp	1,196
*One hour tractive effort, lb	22,600
*One hour speed, m.p.h.	24.3
*One hour current rating, amp.	800
*One hour output, hp	1,465
Starting tractive effort at 25% adhesion, lb	42,500

*Rating given on 1,500 volts at trolley, and motor fields shunted.

Manual knife-blade switches in the main circuits perform the following operations: Selection of trolley, pantograph, or third-rail shoes; connection of the main and auxiliary circuits to the bus line couplers; connection of the traction motor circuits to the source of energy; isolation of individual pairs of traction motors in the event of damage.

Master controllers are of the recently developed cam-operated type. In this the operating lever causes a camshaft to revolve, opening or closing individual contactors in a manner similar to that found in the conventional type of pneumatic cam-operated main-motor controllers used for multiple-unit car service. The reserver handle is mechanically interlocked with the main handle.

Protection for the electrical equipment is afforded by an inclosed expulsion type fuse in the main circuit ahead of the main switch and auxiliary fuse. Individual motors are protected by a series overload relay.



Control equipment and resistors are compactly mounted in a compartment in the center of the locomotive cab

When the locomotives are assigned to territories with different operating voltages, change-over of the main circuits from 1,500 to 600 volt operation, or vice versa, is facilitated by terminal boards to which the motor and grid connections are brought.

There are two traction motor-blower sets, each consisting of a 1,500-volt d.c. motor driving a multivane blower. Each set furnishes air to the pair of motors located in the truck beneath it. The blower motor field coils, armature, brushes, and brush-holders are interchangeable with those of the compressor motors.

The two compressors are of the CP-130, 1,500-volt type, and are designed to deliver 50 cu.ft. of free air per minute each when pumping against a reservoir pressure of 90 lb. per square inch. The compressors are of the single-acting, single-stage type with horizontal cylinders. When the locomotives are asigned to 600-volt territory the compressor motors, blower motors, and the motor of the control motor-generator set will be provided with armatures, field coils and brush rigging differing in electrical characteristics from, but physically interchangeable with, these parts furnished for 1,500-volt operation. Control and lighting energy is furnished by a 2 kw. 1,500/32-volt motor-generator set, which floats across and charges a 200 amp.-hr. "Exide" battery.

Bus line coupler sockets, plugs and jumpers permit emergency operation of two locomotives by means of power furnished solely from either.

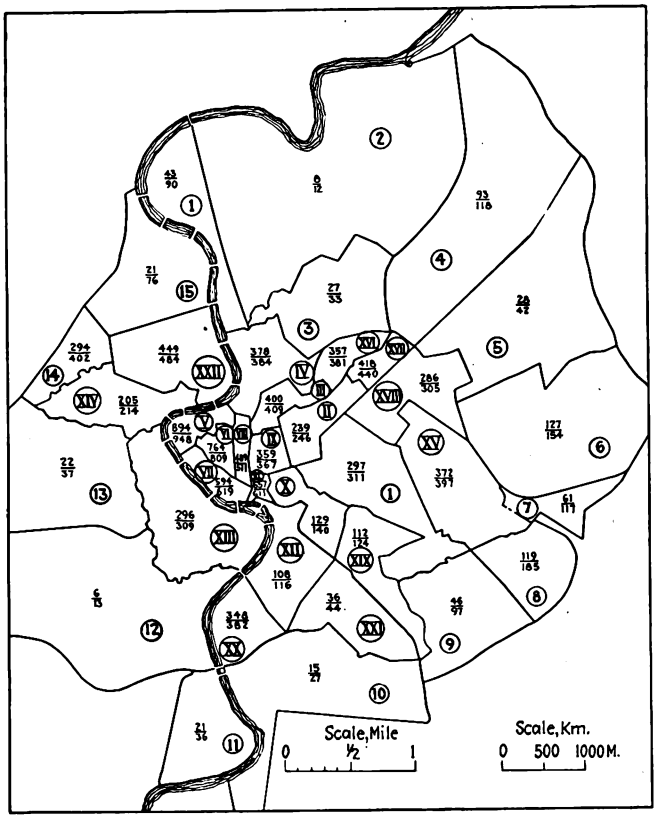
The air brake equipment is of the straight and automatic type manufactured by the Westinghouse Air Brake Company. Each truck has two 10x12-in. brake cylinders mounted on the truck frames and working the brakes for each adjacent pair of wheels. Two air tanks suspended beneath the platform and between the trucks have a total capacity of 43,000 cu.in.

Digitized by Google

Rome to Have

MODERN

Construction of rapid transit line will provide direct routes connecting the principal points in the center of the city with six outlying terminals. It will round out a unified transportation system in which surface cars serve the major portion of the city with buses in the congested central area



Rome population density by districts, 1921 and 1927

The population density is given in inhabitants per hectare, a hectare being equal to 2.47 acres. The upper figure is the density in 1921, the lower is the density in 1927. Roman numbers in circles designate rioni (wards) in the central city and Arabic numerals in circles designate quartieri (districts) in the outer territory now also included in the city of Rome

RAPID transit for the city of Rome, Italy, has been brought much nearer by the preparation of detailed plans for a subway system which are now being studied by the Superior Council of Public Works. The project calls for three lines with a total of 15¼ miles of route. It is estimated that construction work can be completed in 12 years. Additional lines totaling 19½ miles, proposed for later construction, to round out the system, could be completed in 25 years.

Of the three routes included in the first group, as shown on the map, A, the one proposed for immediate construction, is from Piazza Verbano to the Ostia railroad station, with a branch from Porta Pia to Sant' Agnese. The second is that portion of route C between Piazza Re di Roma to Stazione Termini, followed by the remainder of the line C, from Stazione Termini to Viale delle Milizie. Finally, route B would be built from Viale delle Belle Arti to the Ostia station.

These plans are the result of proposals which date back to 1924. In Italy, a city railway entirely within a municipality is under the jurisdiction of the local government, except in the city of Rome, in which all rights are reserved to the national government. In August, 1926, the Minister of Public Works appointed the technical committee to plan a rapid transit system, which has just rendered the report under consideration.

In making the survey, two purposes were kept in view. First was the relief of traffic congestion in the center of the city. This area has winding streets cramped between buildings whose historic and artistic character prohibits removal or modification to provide wider roadways. With the increasing use of automobiles, traffic jams have become so bad that vehicle movement is almost impossible. The second purpose was to permit a redistribution of the population so that more people can reside in the outer districts. The need for this will be seen from the population maps, which give the number of inhabitants per hectare for the wards (rione) of the older central city and the corresponding districts (quartiere) of the outer section.

It will be seen that the three rapid transit lines proposed will skirt the heart of the city, joining Stazione Termini, Piazza Colonna and Piazza Venezia, with six branches extending toward the most important outlying districts. In order to promote flexibility of routing, track connections will be made at two points, Piazza Venezia and Stazione Termini.

Selecting the Type of Tunnel

Shallow subways built by the cut-and-cover method were rejected, in part on account of the cost. It was also considered inadvisable to disturb sections of the ground which might contain material of archaeological importance. Accordingly, the plans have been prepared for the tunneling method such as is used in railroad construction. Toward the outer ends of the line, however, the plans call for shallow subways using the cut-and-cover method. In the lowest section of the city, in the vicinity of the Tiber River, it was decided to use the shield method of tunneling, the tubes being lined with sectional cast-iron rings.

It was deemed inadvisable to adopt special sections for the tube tunnels which differ from those used successfully in Paris and New York. The section shown in one of the illustrations was adopted where possible, and the portion built by the tunneling method is shown in another illustration.

Many test borings along the proposed route indicated that in general there is a superficial layer of soil varying from 7 to 46 ft. In the higher portions of the city there is a stratum of volcanic earth, below which are blue

Digitized by Google

SUBWAY

By

Engineer Ugo Vallecchi

Director of Traffic and of the Technical Office for the Subway System, Rome, Italy

marls and clays. In the lower sections are blue and yellow marls and mixtures of clay and sand. Along the Tiber are large sandy pockets which it is feared may be difficult to handle during the tunneling

While in general the streets are followed, it has been found possible to hold to a minimum radius of 75 m. (246 ft.), limited in general to track at the ends of stations. This radius has made it possible to adopt a car width considerably greater than that used in the Paris subway, without increasing the dimensions of the masonry tunnel or the cast-iron tubes at curves of minimum radius.

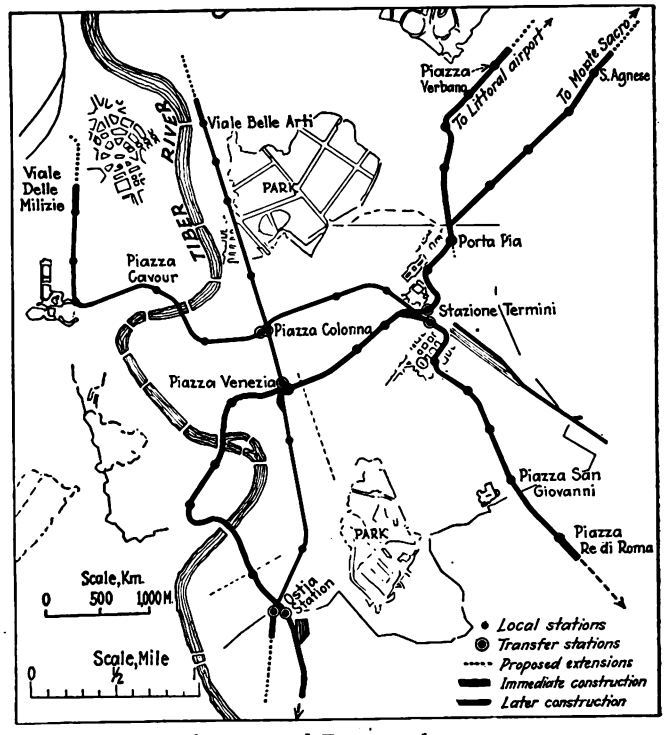
In this connection a study of the maximum permissible speed was made. With stations about 500 m. (1,650 ft.) apart, it was found that a maximum speed necessary to give good schedules was 60 km.p.h. (37.3 m.p.h). It was decided to use a super-elevation of 17 cm. on curves as the maximum. This permits a speed of 37.7 km.p.h. on a 75-m. radius, 45.4 km.p.h. on a 100-m. radius and 59 km.p.h. on a 150-m. radius. The lines also have been laid out so that a straight section of at least 80 m. is left between tangents to circular curves, permitting parabolic easements, with intermediate horizontal straight track capable of containing the four axles of a car between curves.

The maximum gradient is 3.8 per cent at one point on line A and 3.7 per cent at one point on line C.

A study of the use of approach grades at the entrances and exits to stations, calculated for a straight section of track 500 m. long, showed a 22 per cent economy in energy consumption, a 13 per cent reduction in motive power and a saving in time of 4 per cent. These advantages were found to be offset by the increased difficulty of subway construction, the greater exposure to infiltration of water and the impossibility of running express trains and local trains on the same track. The topography also made it impossible to put more than two consecutive stations at the same level. A compromise profile adopted obtains a portion of the advantages of the approach grades.

Considering Location of Stations

It was desired to keep the distance between stations as great as possible, in order to save construction costs, obtain maximum schedule speeds and simplify construction. A study of various systems showed that in Paris the distance between stations varies from 600 m. to 425 m.; in London it is about ½ mile; in Madrid it is close to 500 m.; in Hamburg, 750 m.; in Berlin it varies from 500 to 1,200 m. The distances adopted for Rome average about 550 m. (0.34 mile).



Map of proposed Rome subway system

The main line *A* is 8.603 km. long, with the branch between Porta Pia and Santa Agnese 2.262 km.; line *B* is 5.410 km. long, and line *C* is 7.944 km. long. In addition, connecting tracks of 0.236 km. are planned, making the total length 24.455 km.

In determining the length of a station, the possibility of operating long trains was set off against the financial necessity of investing as little money as possible for future demands. The normal length of stations finally adopted is 80 m. (264 ft.). This is based on the assumption that the cars will have an over-all length between buffers of 15.2 m. (50 ft.). Five-car trains would be 76 m. (250 ft.) long, and would have ample clearance, while six-car trains, with an over-all length of 90.5 (300 ft.) could also be used with the front and rear doors of the trains closed.

Cars with the dimensions proposed will have a normal capacity of about 150 passengers. A six-car train, then, will have a total capacity of about 900 persons. With a maximum frequency of 90 seconds, there will be a capacity of 36,000 passengers per hour, or for an operating period of 20 hr. per day, an ultimate capacity of 780,000 passengers in each direction.

Independent Station Platforms Adopted

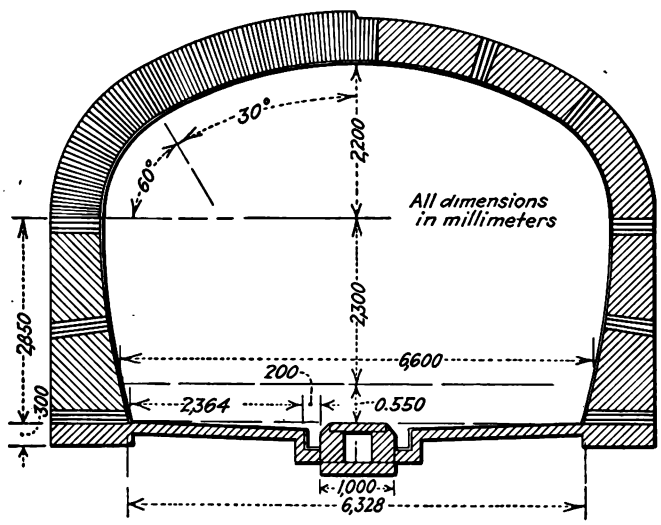
A study of the system of separate platforms on the outside of the track as compared with island platforms was made. In Paris, Madrid, Barcelona and Tokio, outside platforms are used exclusively. In Berlin and Hamburg island platforms are used. In London the ordinary lines have outside platforms, while in the tubes central platforms are standard. Island platforms reduce the total width of the station and simplify the stairways, but lead to interference between incoming and outgoing passengers and, in general, limit the volume of traffic that can be handled expeditiously. It is believed that shorter

Digitized by Google

stops can be made with outside platforms, and passenger travel is confined to one direction. In Paris, the stops average between ten and fifteen seconds, and even in the principal stations seldom exceed twenty seconds, whereas in Berlin the stops equal or exceed double these values. The use of central platforms also involves insertion of curves on each track at each end of the station.

Selection of Rolling Stock

Limiting dimensions of rolling stock are fixed by the subway section. The selection of an internal diameter of 7.3 m. (24 ft.) for the cast-iron tubes thus determines the dimensions of the car. As to clearances it was found that in the Paris subways a clearance between passing trains of 50 cm. was adopted to allow passengers to walk along the tunnel in the event of accident. The adoption of cars with intercommunicating doors, as in the London and German subways, however, makes these clearances



Typical section of Rome subway

entirely unnecessary. Hence it was decided to adopt the dimensions for rolling stock in effect on the principal routes of the Italian State Railways. The minimum clearances between cars on adjacent tracks are 300 mm. (10.8 in.) and 150 mm. (5.4 in.) in a horizontal direction between cars and stationary obstructions. Dimensions of the cars adopted are shown in the illustration. The reduction in width at the ends provides clearance on the curves with 75 m. radius.

Adoption of wheels of 900-mm. (35½-in.) diameter allows the future adoption of motors somewhat more powerful than those previously planned, and gives a height of car platforms of 1.06 m. (41¾ in.) with a clearance of 103 mm. (4 in.) between the wheel and the bottom of the car floor. With station platforms 1 m. (39.4 in.) above the rail level there is a difference of 6 cm. (2 5/16 in.) between the platform and the floor of the empty car. All cars, both motor and trailer, have been designed alike. The couplers will be indentical so that it will necessitate only the addition of electrical equipment to convert the trailers to motor cars, if later developments require.

The principal dimensions of the cars are given in the accompanying table.

The general appearance of the cars is indicated in the plan. There will be three doors on each side, 1.5 m. (4 ft. 11 in.) wide. These doors will be of the double sliding type, automatically operated.

Longitudinal arrangement of the seats was adopted to give easier circulation of passengers in the car and to allow better lighting. Since it is proposed, at least experimentally, to provide for two classes of passengers, the trailers can be divided into two parts, permitting one to be finished and upholstered for first-class service.

The seating capacity of the cars is normally 32. There are places for 121 standing passengers in the motor cars. The trailers will have 36 seats and 119 standing passengers. A normal train of five cars will then have capacity for 771 passengers, of whom 168 are seated. The weight will be 184 kg. (405 lb.) per place offered.

Ventilation will be provided by opening the upper section of the windows, or by means of automatic suction fans. This was considered preferable to the use of a monitor deck, being less expensive, more substantial, and better in appearance. The normal train will consist of three motor cars and two trailers, alternating. Until the necessity for greater capacity arises, three-car trains, consisting of two motor cars with a trailer between, will be used. Automatic couplers will make mechanical, air and electric connections between cars.

Substantial Track Construction Proposed

The track will be constructed with Italian State Railway standard rail type FF.SS, weighing 50.6 kg. per lin. m. (102 lb. per yd.), laid on oak crossties, 26 being used in each section of 18 m. This corresponds to a spacing of 27¼ in. Every fifth crosstie will be extended to support the third rail. The same type of track has been adopted not only for the main lines, but also in the stations. In the carhouses and yards, as well as on side tracks rail weighing 36 kg. per m. (73 lb. per yd.) will be used, with 24 crossties for every 18-m. section. On curves of 300-m. radius or less, inside guard rails will be used. The ballast will be made up of gravel and will have a depth of 55 cm.

750-Volt Third-Rail System Used

It is proposed to use the 750-volt direct current system. Although the 3,000-volt d.c. system will be used for future railroad electrification in Italy, it was felt that the clearances with low voltage would be less and that the saving in cost in the distribution system would not have offset the higher cost of the equipment and its maintenance. It was pointed out that with few exceptions all other rapid transit lines in the world use between 800 and 600 volts. One Barcelona rapid transit line uses 1,700 volts for the third rail and the other 1,400 volts with overhead trolley. The Nord-Sud line in Paris has a three-wire system at 1,200 volts, but only 600 volts between each third rail and the return wire. In Berlin and Hamburg 800 volts are used with the third rail. All the other rapid transit systems, including those in America, Paris, Madrid, and Tokio, employ 600 volts. Of these the one in Madrid is the only one using an overhead contact line.

All calculations of motor power were based on the use of a standard train of three motor cars and two

Principal Dimensions, Rome Subway Cars, as Proposed

	Meters	Feet and Inches
Length of body	14.5	47–7
Width of body	2.6	8–6¾
Height, rail to roof	3.3	10–10
Rigid wheelbase	10.0	32–9¾
Truck wheelbase	2.3	7–6½
Length over buffers	15.2	49–10¾
Weight of motor car, metric tons (2,204 lb.)		34
Weight of trailer car, metric tons		20

Digitized by Google

trailers weighing 178 metric tons. The braking rate is assumed at 0.85 meters per second (1.9 m.p.h.p.s.). It is planned to use automatic acceleration and, with an adhesion coefficient of 18 per cent, to reach a speed of 40 km. per hour (25 m.p.h.) in 14 seconds. This calls for an average acceleration up to full motor voltage of 0.8 meters per second per second (1.8 m.p.h.p.s.) and a maximum acceleration of 1.15 meters per second per second (2.6 m.p.h.p.s.). On this basis the type of motors adopted has a one-hour rating of 170 hp. at 750 volts and a continuous rating of 130 hp. at 750 volts. There will be four such motors per motor car, with pairs connected permanentaly in parallel. Electro-pneumatic control will be employed and remote electro-pneumatic devices will govern the action of the third-rail shoes and motor compressors. Each motor car will have a switchboard in the cab at each end. No control equipment is included on the trailers. Multiple-unit control will be used and the trains can be operated from any cab.

The car lighting will be from the 750-volt supply, with an emergency storage battery circuit. Quick-acting air brakes will be employed, with two brake shoes on each wheel.

Electric power will be supplied by a third rail of special steel located between tracks. Copper feeders will be connected to the third rail at each station, by remote control switches. The track will form the return circuit, with inductive bonds so as not to interfere with the signal circuits. The feeders were calculated on the basis of standard operation with three-car trains at intervals of two minutes 30 seconds, while by using the reserve equipment in the substations it will be possible to run either with trains of five cars at the same headway or with trains of three cars at 90 seconds headway.

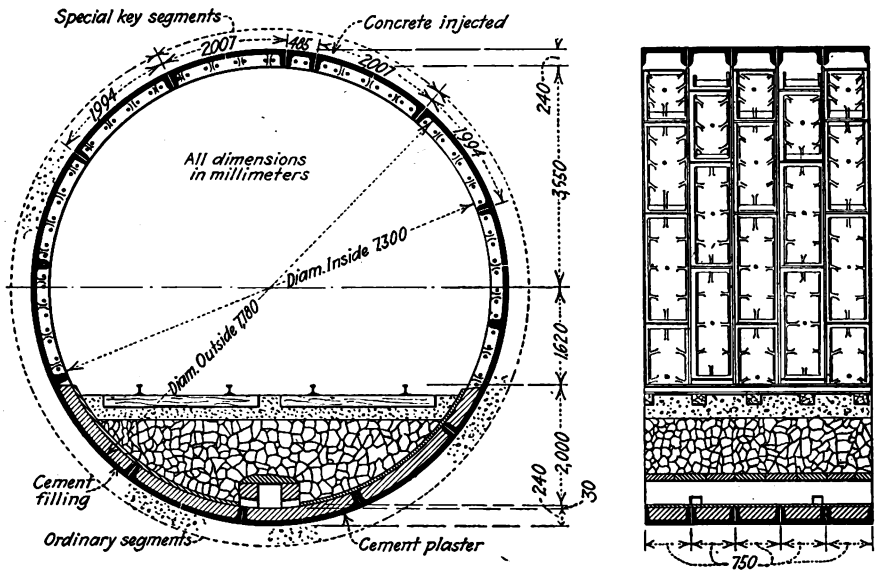
Power will be converted in five substations with a total installed capacity of 30,000 kw., of which 10,000 kw. normally will be held in reserve. An investigation is being conducted to determine the feasibility of using mercury vapor converters instead of rotary converters, and doing so in connection with the regeneration of energy on motor cars.

The substations will be fed from two three-phase lines at 8,200 volts and 45 cycles. For the first line to be placed in service there have also been provided two storage batteries of a total capacity of 1,000 amp.-hr. for discharge in ten minutes, and an average potential of 500 volts. In the event of an interruption in the supply, these batteries will enable any train which may be between stations to reach the nearest stop. These batteries are also connected to the emergency lighting circuits of the stations and of the line.

The block signal installation was designed to permit a frequency of 40 trains per hour, or a headway of 90 seconds. All signals will be of the color-light type. Caution signals will be installed only where the stop signal may not be visible at a sufficient distance for the motorman to stop his train when proceeding at maximum speed.

An automatic train stop will set the brakes and cut off current from the motors of any train that may pass the signal. At the entrance to each station, a safety signal will be located at such a distance from the end of the platform or switch point that a train whose brake has been set by the automatic stop will positively be stopped before running into a standing train in the station. Each station will also have departure signals at the leaving end of the platform. The automatic block signals will show normal clear indications, while the interlocking signals will show normal stop indications and must be cleared for the passage of each train. The signal system adopted is controlled by alternating current in the track circuits. The track circuits, control circuits, automatic stop devices and lamps will be fed by three-phase current of 220 volts. Communication between stations, switch cabins, substations and depots will be by means of a telephone system.

The subway will normally be unlighted. If the current fails an emergency lighting system fed by the storage batteries will be cut in automatically so that passengers may be able to make their exit. An independent system of emergency lighting fed from a separate storage battery will be installed in the stations.



Section of tunnel of concentric cast-iron rings used under the Tiber River and at other points

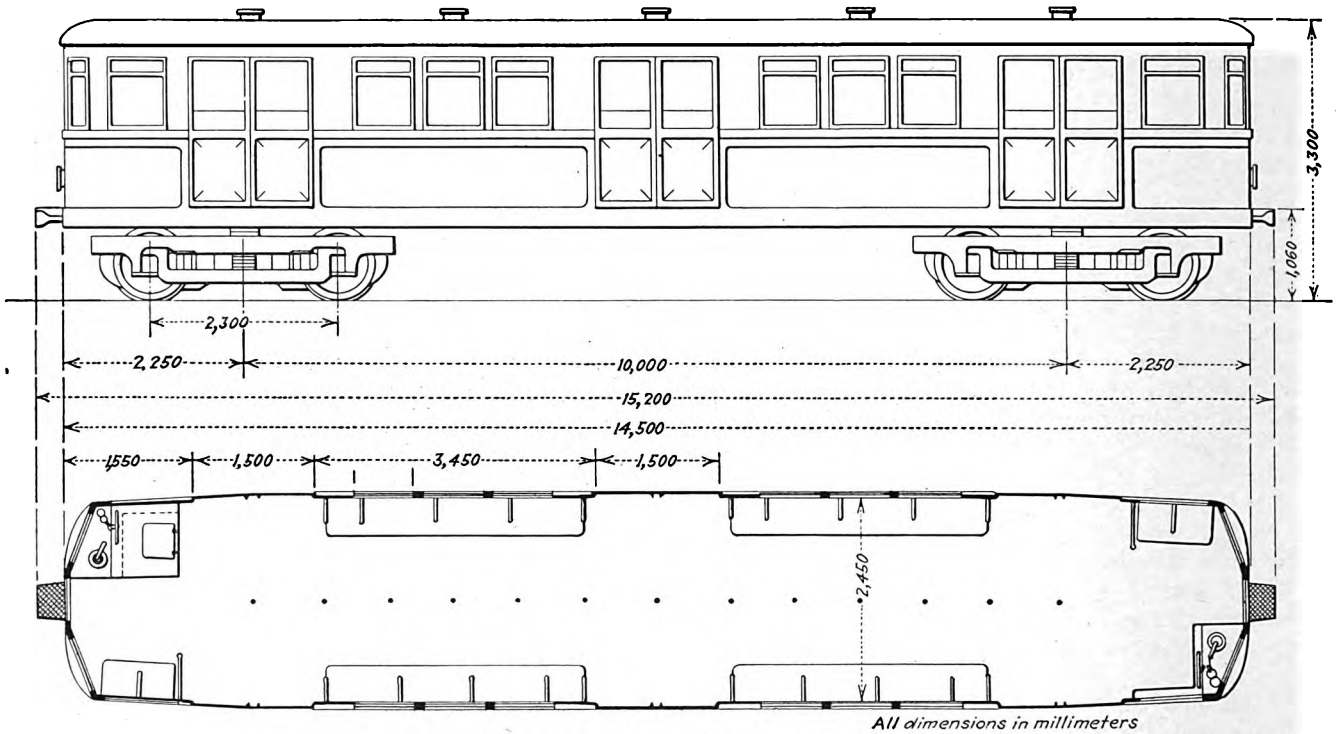
Along each track there will be a pair of exposed telephone wires. By bringing them into contact the automatic switches in the substation will be actuated. The same two wires can be used by the train crew to communicate with substations by means of a portable telephone set. Fire extinguishers will be placed in stations and along the line, their location being indicated by blue lamps fed from the signal circuit. Special switches in the stations will permit the crew to set the signals against movement, in the event of a blocked track.

Shops and Car Storage

Adjacent to the terminal on line A, adjoining the station of the Rome-Ostia line of the state railway, will be the carhouse and shops. Two large adjoining carhouses, 84 m. by 21 m. each, will contain twelve storage tracks, eleven of which are provided with pits for the inspection of the cars. Each track will accommodate a five-car train, making the total capacity 60 cars.

The main repair shop will be placed back of the storage house, being separated by transfer tracks. The shops will have a series of seven bays and will cover 4,400

Digitized by Google



Proposed car for the Rome Subway

Motor and trailer cars will be identical in general dimensions. Control equipment will be placed on motor cars only

sq.m. (47,000 sq.ft.). For six of the bays, intended for repairs on rolling stock, a transverse crane is provided. The remaining bay is reserved for servicing of the lines, tracks, electrical system, signals and miscellaneous work. In front of these bays is to be a two-story building, 2,320 sq.m. (25,000 sq.ft.) in area. On the ground floor will be rooms for the machinery, tools and miscellaneous equipment connected with car repairs. The second floor will contain the administration offices and space for lodgings for officials. The storehouse will be in the end of the shop and office buildings and in the adjacent yards.

There will be a yard with a total area of 4,900 sq.m. (50,000 sq.ft.) in which material necessary for operation will be received. This yard will be served by tracks of the city surface line and through a connecting spur by the state railway system. The storage yard will be served by a gantry crane permitting direct unloading from the cars. There will also be a small storage yard, equipped with pits, and shops for routine night inspections in the terminal stations and in the station at Piazza del Cinquecento on line A.

The proposed schedule calls for the operation of three-car trains on a headway of two minutes 30 seconds. During hours of light traffic the service will be on a five-minute headway. The first runs will start at 5:30 a.m. and the last run will end at 1 a.m. The program calls for the operation of trains with a total capacity of 11,000 passengers per hour in each direction during the rush period. This schedule contemplates the absorption of the business at present handled on the surface cars, so that the plan of co-ordinating the subway system with the present surface car system will be complete.

The construction program provides for the completion of route A within six years. In the two years following the section of route C between Stazione Termini and Piazza Re di Roma should be completed. This will establish rapid transit communication between the center of the city and Piazza San Giovanni, to which point will be transferred the terminal station of the railway to Castelli Romani. In the four years following the second section of route C and all of route B should be built.

The costs of construction and equipment, including damages and allowing for contingencies, are estimated as follows:

	Lire	Dollars
Route A (10.865 km.)	300,000,000	15,750,000
Route C (section between Stazione Termini and Piazza Re di Roma, 3.036 km.)	70,000,000	3,675,000
Route C (section between Viale delle Milizie and Stazione Termini, 4.908 km.)	170,000,000	8,925,000
Route B (5.410 km.)	155,000,000	8,137,500
Total	695,000,000	36,487,500

In order to assure a sufficient return on the capital stock, assistance on the part of the state will be necessary. It is proposed that the state should guarantee the interest on an issue of bonds for an amount corresponding to about two-thirds of the total cost of the work which is equivalent to 90 per cent of the cost of the sub-structure. At the expiration of the franchise, 50 years, or in the contingency of appropriation of the system, the state would naturally become the owner of the sub-structure. The state would also be entitled to participation in the net profits.

Calculations indicate that the remaining routes, including the first portion of route C, can be carried on without further assistance from the state.

Growth of Population in Rome, 1921-1927

	1921	1927
Rioni (wards of central city)	451,097	477,206
Quartieri (districts) of outer city	152,312	236,751
		5,026
Total	603,409	718,983
Suburban districts	28,205	57,064
Agricultural districts	34,426	54,628
Total exclusive of garrisons	666,100	830,675

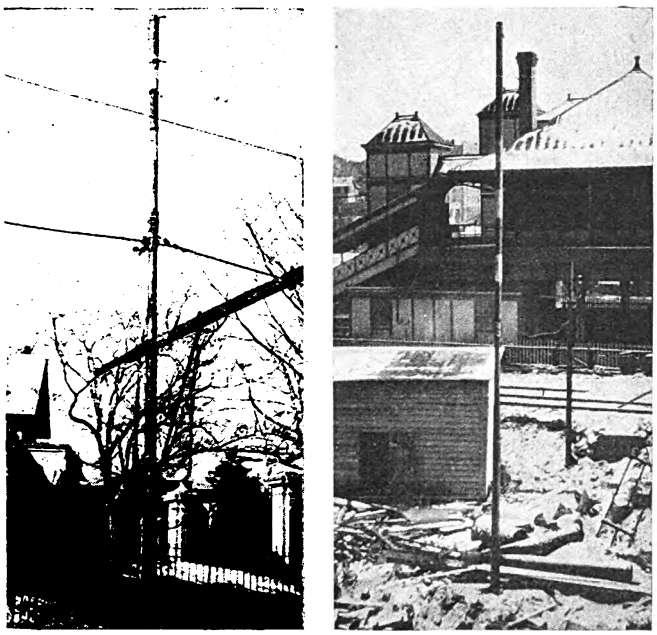
Long Poles Made by Splicing

DUE to the extension of the Bronx River Parkway under 232nd Street, the foundations of some of the span wire poles used by the Third Avenue Railway System, New York, were removed. Two novel methods of supporting the overhead construction were adopted. One was to support both wires by a horizontal arm attached to the pole on the side opposite the railroad cut. An extension approximately 12 ft. long was made to this pole by means of a malleable iron reinforcing clamp. From the top of the lengthened pole guy wires were attached to support the horizontal arm, as shown in an accompanying illustration. This arm projected back a short distance over the sidewalk and was guyed at that end as well as at the long end.



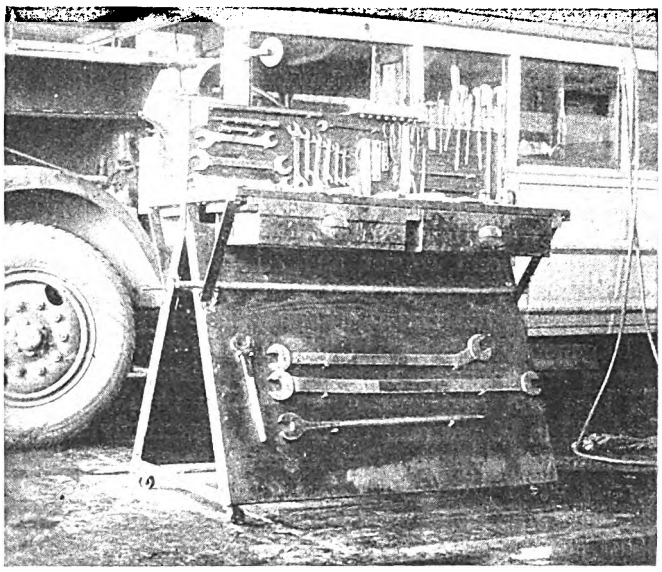
At left—Pole lengthened by splicing to support horizontal arm for attaching trolley wires on Webster Avenue. At right—Extra long pole made by splicing two ordinary poles together with reinforcing clamp

The other method used to support the trolley overhead was the erection of a 60-ft. pole, the foundation of which was in the new cut. To obtain a pole of this length the railway took two ordinary 30-ft. poles and placed one upside down on top of the other, joining them by a malleable iron reinforcing clamp.

Portable Rack for Special Bus Tools*

By Stewart Palmer
Foreman Berea Garage
Cleveland Railway

TO SPEED UP bus inspection a semi-portable tool stand is used at the Berea Road Garage of the Cleveland Railway to hold all special wrenches needed, as well as a supply of nuts, bolts, lamp bulbs and other small items necessary for this kind of work. The stand is placed between two pits where it is readily accessible for the mechanics working in each inspection pit. This material would normally be kept in the stockroom but because



Rack for special bus tools and equipment speeds up the work in garages of the Cleveland Railway

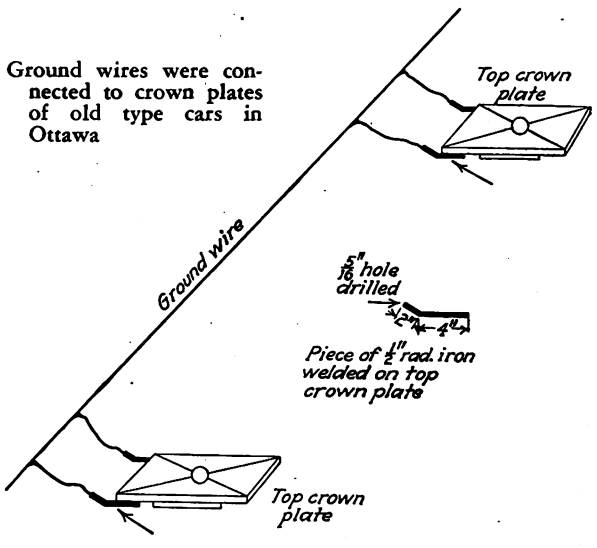
the same work is performed in these two pits continually, it is more economical to place special tools and equipment on the floor. At the close of the inspection period, the rack is moved into the stockroom.

Cars Grounded on Crown Plate*

By J. Munford
Electrical Foreman
Ottawa Electric Railway, Ottawa, Canada

DIFFICULTY has been experienced in Ottawa to keep ground wire connections tight on old type cars, cars frequently being pushed in dead on account of this failure. To overcome this, four pieces of ½-in. round iron 6 in. long were cut and bent at 45 deg. at a distance

Ground wires were connected to crown plates of old type cars in Ottawa



of 2 in. from one end. A $\frac{5}{16}$-in. hole was drilled in the short end and tinned. This iron ground connection was then welded on the long end to the top crown plate, with the tinned holes upward to retain the solder while the taps from the main ground wire were being soldered in place. Since this installation none of these ground connections has given any trouble.

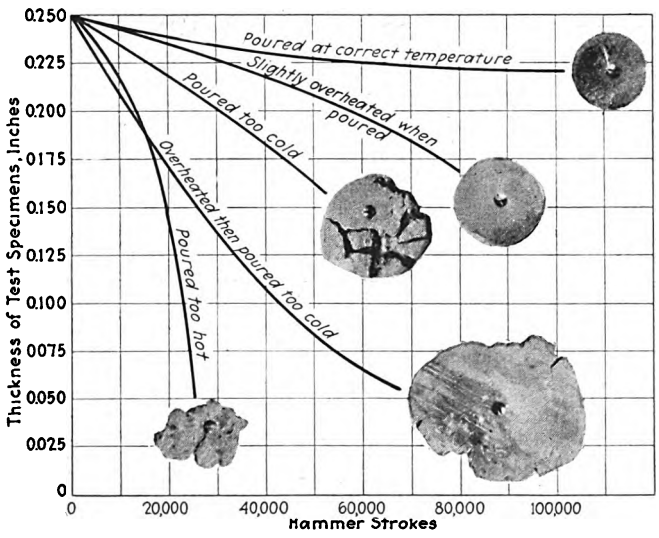
Tests Show Importance of Correct Babbitting

By J. S. Dean
Renewal Parts Engineer
Westinghouse Electric & Manufacturing Company

BABBITT metal commonly used for lining bearing shells was originally a composition of 89.3 per cent tin, 3.6 per cent copper and 7.1 per cent antimony. More recently a great variety of bearing metals have been brought out under different trade names.

In general, the various babbitt metals used in railway motors are divided into two distinct classes, known as tin base and lead base alloys. They usually contain from 80 to 90 per cent tin or lead respectively as their fundamental element. Both classes give good results in service when properly handled during the melting and pouring process while babbitting the bearing shells. Most electric railway operators seem to favor the use



Results of hammer tests of babbitt metal poured under various conditions

of the tin base alloy for armature and axle bearings, although a few have tried the less expensive lead base alloy as an experiment with good success.

To show the variety of materials used in some of the well-known babbitt metals, the following table represents five different brands of tin and lead base alloys commonly used:

Composition of Babbitt Metals

	Tin Base Alloy — Per Cent				Lead Base Alloy — Per Cent			
Sample	Tin	Copper	Antimony	Sample	Lead	Copper	Antimony	Tin
(1)	85	7.5	7.5	(1)	64	1	14.4	20.6
(2)	83.0	5.0	12.0	(2)	81.3	1.8	11.4	5.5
(3)	*89.3	3.6	7.1	(3)	76.2	.2	14.4	9.2
(4)	90.0	2.0	8.0	(4)	82.3	.2	16.6	.9
(5)	83.4	8.3	8.3	(5)	79.5	.8	19.5	.2

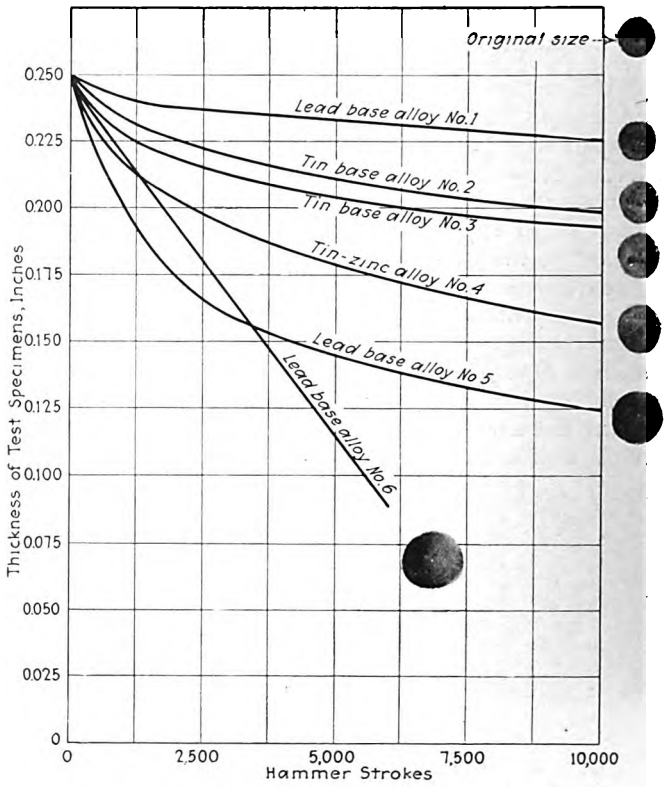
*Original formula of Isaac Babbitt.

The mechanical strength of the two different types of alloy are shown in the following table:

Strength Tests of Babbitt Metals

Class of Alloy	Ultimate Stress — Tension	Ultimate Stress — Compression	Elastic Limit — Tension	Elastic Limit — Compression	Per Cent Elongation in 2 In.	Brinnell Hardness
Tin base.....	11,875	16,800	5,000	7,000	5.5	*30
Lead base....	10,900	14,500	3,200	3,000	1.0	*24

*These tests were made on sample specimens 2 in. in diameter and ½ in. thick



Results of hammer tests of babbitt metal of various compositions

The results of vibration and pounding tests made on a number of sample bearing shells which were babbitt lined, tin and lead base alloys being used, show interesting results. Tests made on bearing shells (tinned before babbitting) show that a tin base alloy resists failure due to pounding and vibration 2½ times better than a lead base alloy. Similar tests made on bearing shells (not tinned before babbitting) show that a tin base alloy resists failure due to pounding and vibration five times better than a lead base alloy. These bearings were subjected to two different tests. In the first test the bearing was mounted in a specially designed hammer machine which pounded the flange of the bearing. In the second test a special vibration testing machine was used which delivered a series of rapid vibrations to the body of the bearing shell.

Test pieces of babbitt metal of 1 in. diameter and ¼ in. thickness were prepared and subjected to a series of hammer blows, after which the thickness of the pieces was measured and the corresponding number of strokes recorded. Results of these tests show the importance of pouring babbitt metal at the proper temperature, as may be seen from the accompanying curves.

Results of actual service tests made on railway motor armature bearings lined with an approved grade of tin and lead base alloy show that either class of these babbitt metals will operate satisfactorily in service. The following figures were obtained from actual service bearings:

Service Tests of Babbitt Metals

Kind of Service	Babbitt Lining	Armature Location	Actual Mileage	Maximum Wear
City.....	Tin base	Pinion end	290,000	0.061 in.
City.....	Tin base	Commutation end	290,000	.006 in.
Interurban.	Lead base	Pinion end	240,000	.028 in.
Interurban.	Lead base	Commutation end	240,000	.037 in.
City.....	Tin base	Pinion end	374,900	.075 in.
City.....	Tin base	Commutation end	374,900	.025 in.

Temporary crossover used by the Cleveland Railway is easily and cheaply installed

Economical Overhead for Temporary Crossovers*

By Angus G. Scott
Assistant Superintendent of Overhead Lines
Cleveland Railway

ERECTION of overhead crossings over portable track crossovers is facilitated at Cleveland by the use of a 2½ in. x 1½ in. x 12 ft. board, which acts as an intermediate span wire. This board is provided with three barn hangers which move freely back and forth. The first step in erecting a temporary crossover is to install a frog over each switch. The frogs are then connected by a short piece of $\frac{5}{16}$-in. or $\frac{3}{8}$-in. stranded span wire which is prevented from sagging and is kept in alignment by the hanger on the board. Reclaimed ears, frogs and wire are used in the installation of such a temporary overhead crossover. This device can be installed in about 30 minutes at a saving of approximately $3 in labor costs alone, as compared with the old method of installing overhead crossovers.

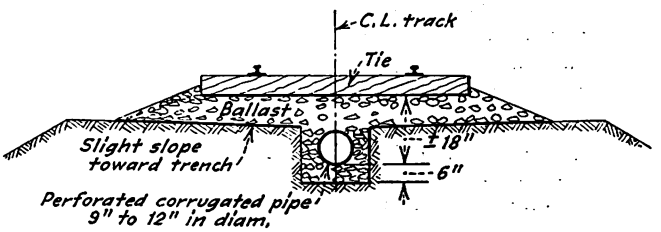
Center Subdrainage System Reduces Track Maintenance Cost

DRAINS placed directly under the center of the electric railway track of the East Bay division, Southern Pacific Company, Berkeley, Cal., have lessened track maintenance work and insured better riding qualities. The installation of these drains is part of an extensive improvement program which has been in progress for some time past. The project involves the complete reconstruction of the track using 90-lb. T-rail with creosoted ties on rock ballast.

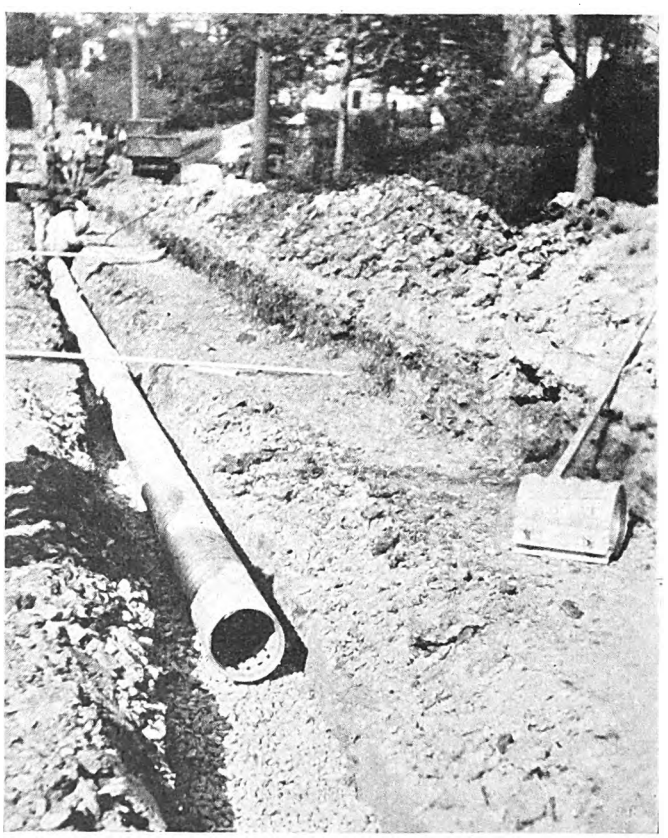
Poor drainage conditions on the old track had been a fruitful cause of low and pumping joints, bumpy surface and heaved pavement. To safeguard against such conditions on the new construction, a system of center subdrainage was designed. Placing of the drains under the center of each track is believed to have several advantages over the old method of placing subdrains to the side of and between tracks. By placing the drains in the center, sloping the subgrade slightly toward the trench and using a pervious backfill, one line of drain is sufficient to remove water quickly before it has a chance to lessen the bearing power of the soil. A drain so placed stabilizes the soil supporting the track and its weight of traffic.

However, successful use of this design demands a drain of considerable strength if it is to bear without breakage the shock and impact of traffic. Even where it is desired to lower the water table and the drain is placed at such a depth that the impact factor becomes of less consequence than the dead load, a non-crushable drain of continuous construction which will not disjoint in unstable and shifting soils is necessary to avoid costly replacement work.

The trench was excavated to a width of from 9 to 12 in. greater than the diameter of the pipe, to permit careful tamping of the rock backfill around the pipe. The trench depth was maintained at 6 in. below



Drainage system used for open track on suburban lines



Perforated iron pipe on a 6-in. layer of coarse rock used for track drainage in Berkeley, Cal., by East Bay division of Southern Pacific Company

*Submitted in Electric Railway Journal Prize Contest.

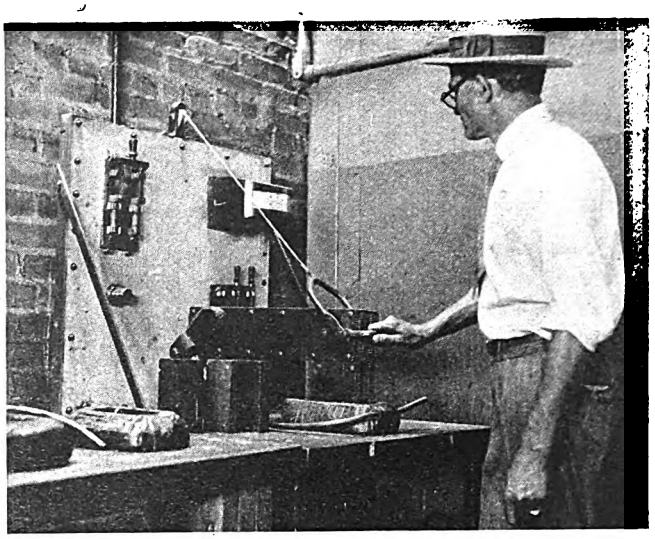
Digitized by Google

the flow line to provide for a bed of crushed rock below the pipe. The flow line was kept at approximately 18 in. below the ties, varying somewhat because of the grade. Where it was necessary to lower the water table this depth was increased to any desired depth for which it was possible to secure an outlet. The rock backfill was carried to the top of the trench, where it became integral with the ballast section. It is considered to be highly essential that rock backfill be used to the top, in order that direct and rapid interception of run-off, rather than slow percolation through soil, will result. The surface of the subgrade was sloped slightly toward the trench for the same reason. In general it was decided to install a drainage system conforming to this design over originally swampy land, through cuts or side-hill sections, or where adobe pockets in the original fills were impounding water.

Testing of Field Coils*

By C. B. Hall
Chief Clerk Mechanical Department
Virginia Electric & Power Company, Norfolk, Va.

SIMPLE and effective apparatus for testing field coils has been developed in the shops of the Virginia Electric & Power Company, Norfolk, Va. A transformer or "growler" was assembled for this purpose by the electric shop foreman. A table, measuring 30x30 in., was made of 2x2-in. angle iron and topped with a piece of 1½-in. hickory. The table back is of transite board on which is mounted a 30-amp. safety switch, a 50-amp. a.c. ammeter and knife switches for short circuiting the ammeter and selecting the different number of turns in the transformer winding. The core is made of No. 20 gauge sheet steel, the cross section being 4x5 in., while the inside of the rectangle measures 9½ in. vertically and 12 in. horizontally. The top horizontal member is hinged and counter-weighted so that it may be easily moved up and down providing free space for putting a field coil in place for test and at the same time making it easy to close the iron circuit during the testing. The front vertical leg is flush with the surface of the table. A removable piece represents the portion of the iron circuit between the short vertical leg and the moving horizontal member. The primary winding is wrapped around the portion of the iron under the table, No. 10 A.W.G. double cotton-covered wire being used. The winding has 180 turns, with taps at 60 and 90 turns



Assembly of field coil testing apparatus

leading to knife switches. The 90-turn winding is used for regular testing, the 60-turn winding for burning out a shorted turn quickly, and the 180-turn winding when repairing a shorted coil. Field coils are tested by placing them on the table and closing the iron circuit of the transformer. The safety switch is then closed, energizing the transformer. The knife switch connected across the ammeter is then opened. If the field coil is without shorted turns, the ammeter will indicate a current of exactly the same value as it does without a field coil on the transformer. If the field coil has any shorted turns, the current will be greater, the degree of short circuit being indicated by ammeter reading. It is for this reason a switch, short circuiting the ammeter, is used because a badly shorted coil will show an ammeter reading in excess of 50 amp. This apparatus has saved time and labor by the detection of defects at an early stage.

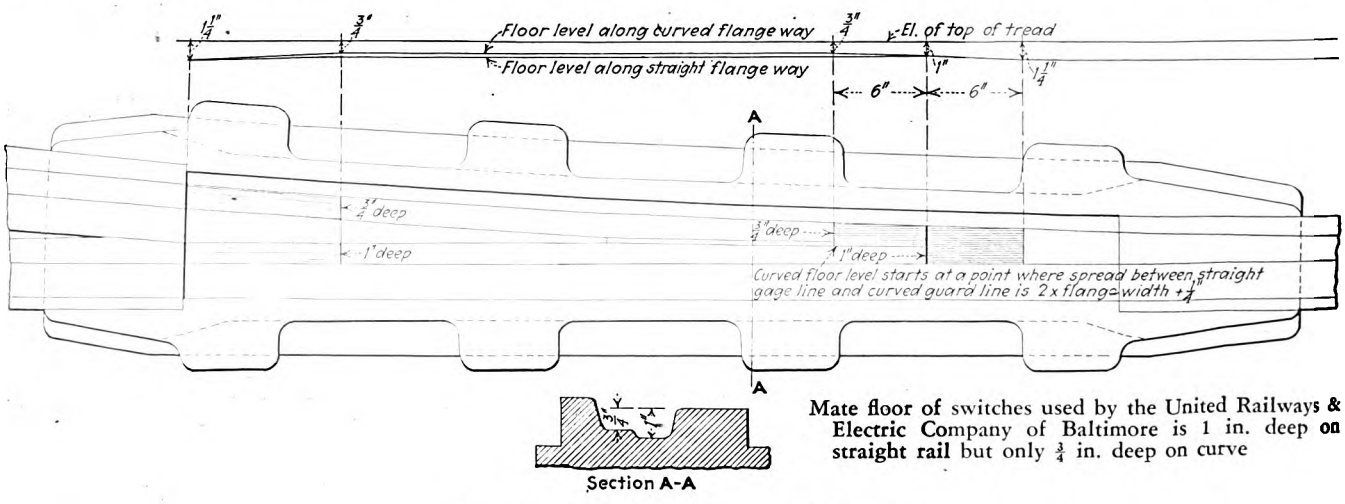
Redesigned Mate Floor Prevents Derailments*

By W. P. Davis
Roadmaster United Railways & Electric Company, Baltimore, Md.

AT TURNOUTS where the principal car movement is on a straight track and where floor bearing mates are used, a groove is soon worn in the floor on the straight side. This tends to cause derailments with car



Mate floor of switches used by the United Railways & Electric Company of Baltimore is 1 in. deep on straight rail but only ¾ in. deep on curve

Digitized by Google

movements on the curve side. To avoid this trouble the United Railways & Electric Company of Baltimore has redesigned its switches so that the floor on the straight side is made 1 in. deep and the flanges do not touch, while on the curve side the floor is only ¾ in. deep. The approach to this higher floor is made at such a point that the car wheels will have already been guided into position by the switch tongue before the flanges touch the high floor. This design was adopted several years ago for wheel flanges 1¼ in. wide and 34 in. deep, and proved very satisfactory.

Shunting Motors to Obtain Greater Speed

By R. S. Beers
Transportation Engineering Department
General Electric Company, Erie, Pa.

SUBSTANTIAL increase in the operating speed of existing street cars can sometimes be simply and cheaply accomplished by shunting the motors with non-inductive shunts. This has been tried successfully in several cities. It has been done on a considerable number of equipments by the Key System Transit Company and the United Railways & Electric Company of Baltimore. Where the operation includes considerable suburban running, with relatively infrequent stops, a material increase in schedule can be accomplished; the method is of little or no value, however, if the stops are close to each other.

The recommended practice is to accelerate the car on full field and, after all the resistance has been cut out of the circuit by the controller, to shunt the motors. As there is a considerable increase in current when changing from full field to shunt field, it is customary to have the motor current govern the change through the intermediary of a current relay. This method simplifies the control devices, so that they may be added readily to almost any existing control equipment.

The material used includes one ME-67 field shunting switch, weighing about 105 lb., one EW resistor, weighing about 35 lb., and cable and details. The ME-67 switch is used for either two or four-motor equipments, and includes the governing relay as an inherent part of the device. The EW resistor is used as a shunt for the motor field; all the shunts for either a two-motor or a four-motor equipment are included in the one EW resistor. With a Type K controller it is necessary to add a control finger, and with remote controls it is necessary to add an interlock to one or two of the contactors.

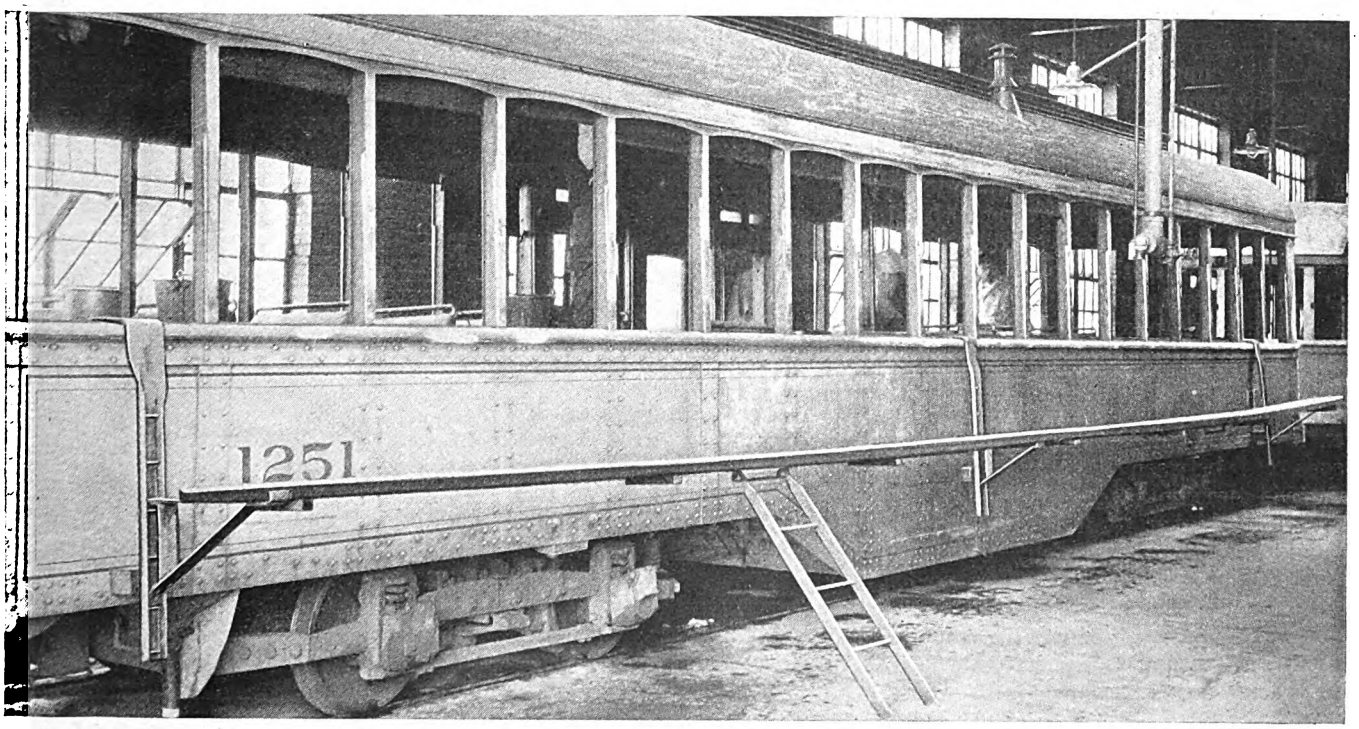
In general the method cannot be applied to advantage to non-commutating pole motors such as the GE-67, GE-80 and W-101. The conditions of operation, car weights, commutation of motors, etc., vary so much that no one can recommend field shunting with certainty of success in every instance. It is recommended that one equipment be installed and an actual test used to ascertain whether or not the method is successful.

Adjustable Scaffold for Car Washing*

By R. C. Sohl
Engineer Mechanical Department Cleveland Railway

HORSES and planking assembled to form a scaffold to reach the upper parts of the car, in the wash house of the Cleveland Railway, have been replaced by a set of brackets which hang from the window sills of the car. These brackets are constructed from 3-in. channel iron, bent to the shape of the window sill. They are adjustable by means of sets of horizontal rivets. The parts which rest on the window sill are covered with canvas and leather as a protection to the woodwork. This new equipment not only saves valuable space occupied by the horses formerly used, but also saves much of the

**Submitted in* Electric Railway Journal *Prize Contest.*



Brackets suspended from the windows support platform used in car washing or painting in the shops of the Cleveland Railway

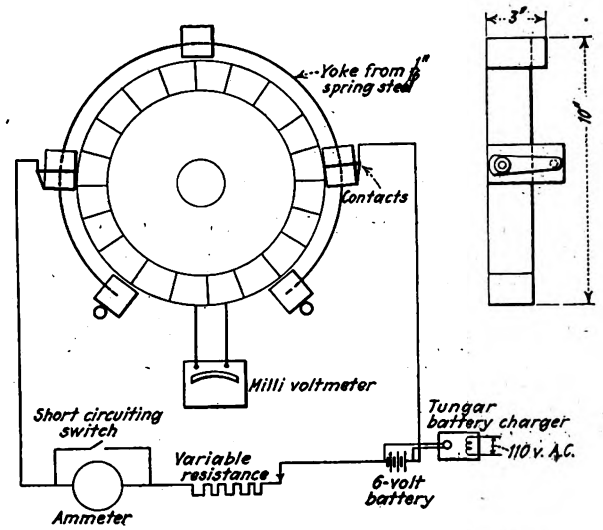
Digitized by Google

time required to set them up. Safety has been increased considerably. Whereas the old equipment rested on the floor and was unstable on a soapy concrete, the suspended scaffold eliminates the danger of slipping. The cost of a bracket is about $2.50. Four are necessary for one side of a 50-ft. car.

Test for Partially Open Circuit*

By H. J. Beadle, E.E.
Dallas Railway & Terminal Company

READY detection of cracked or partially cracked coil leads has been attained by an additional test recently installed by the Dallas Railway & Terminal Company. A yoke which is made of $\frac{1}{16}$-in. spring steel is supported



Circuit arrangement in making open circuit test

on five fiber blocks and will fit the commutator of any armature from 25 to 65 hp. This steel yoke is therefore insulated from the bars and supports the leads which carry the current to the commutator while testing. This current is supplied from a 6-volt storage battery and is varied by means of a rheostat. After a current of about 6 amp. has been attained, the ammeter can be short circuited and thus be protected during a time when a great many armatures are being tested. The tungar battery charger is connected to a 110-volt a.c. circuit and in this way the battery is kept in good condition at all times. It is important to keep the battery fully charged so as to insure a constant current while testing. The milli-voltmeter is used to get the voltage drop across each pair of bars and unless the voltages are between bars exactly alike there is something wrong with the armature. A higher reading than normal would indicate a partially open or broken lead and a lower reading would indicate a short between bars. This test is adaptable to modern high-speed motors with small wires where broken or cracked leads become more serious.

Belt Conveyor for Loading Concrete Mixer*

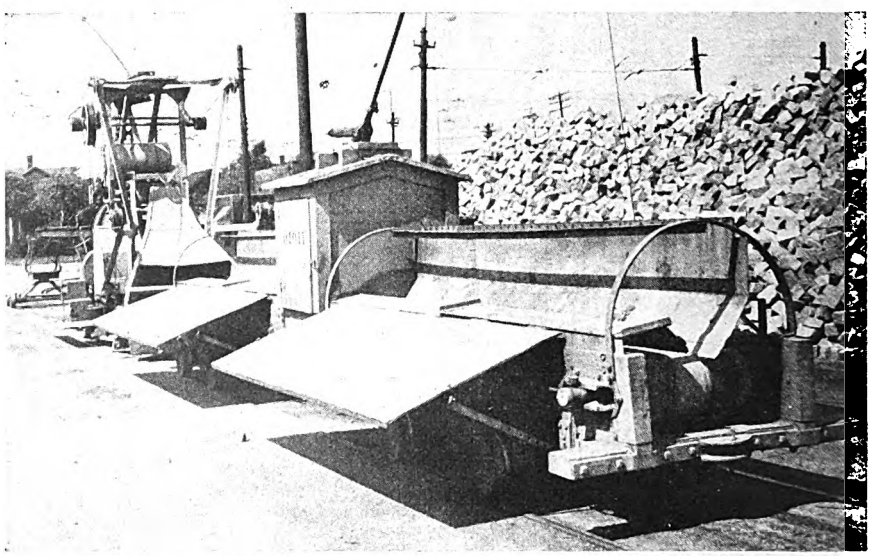
By E. B. Spenzer
Way Department Cleveland Railway, Cleveland, Ohio

TIME and labor are saved in loading material into the skip of a concrete mixer by using a belt conveyor loading device which has been developed by the Cleveland Railway. The method of loading by hand or wheelbarrow resulted in waste of time as the men crowded around the skip. Trucking proved equally costly, and frequently was impracticable when the mixer was placed in an inaccessible location.

With the belt conveyor connected to the mixer by a long draw bar, the material is shoveled on the conveyor from the side where it has been unloaded in a continuous pile from the work trains. One man stands at the skip and puts in the cement from the sacks. He also gages the amount of sand and gravel that the conveyor throws into the skip and when there is enough material for a batch, he blows a whistle as a signal for the men to stop shoveling on to the conveyor. These men stand at intervals along the conveyor for a distance of 30 ft. and have ample room in which to work. In the time required to mix a batch of concrete, the skip of the mixer is loaded. Thus no time is lost.

This conveyor is built on a low frame, 30 ft. long, mounted on two sets of small trucks. An endless belt runs horizontally along the car over two pulleys, one at each end. Guide pulleys are spaced at 3-ft. intervals and at a 45-deg. angle to tilt up the edges of the belt. Inside the edge of the belt and projecting lip are two side boards which prevent the material from going off the belt. Two steel aprons are on the side of the conveyor from which the material is loaded. These extend to within 1 ft. of the pavement and prevent the material from being thrown on to the surface track. The conveyor is operated by a small motor in the center of the car.

The number of men required for the complete job of mixing is reduced from 24 to 11, while the speed of mixing is increased by 20 per cent.



Belt conveyor used by Cleveland Railway for loading concrete mixer saves 53 per cent in labor

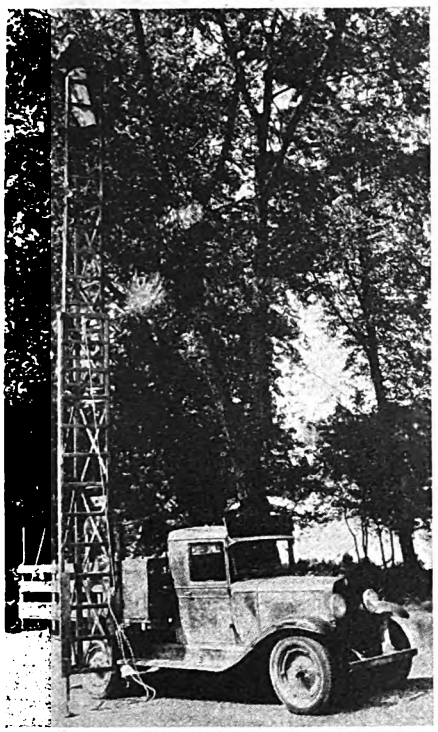
NEW PRODUCTS for the Railways' Use

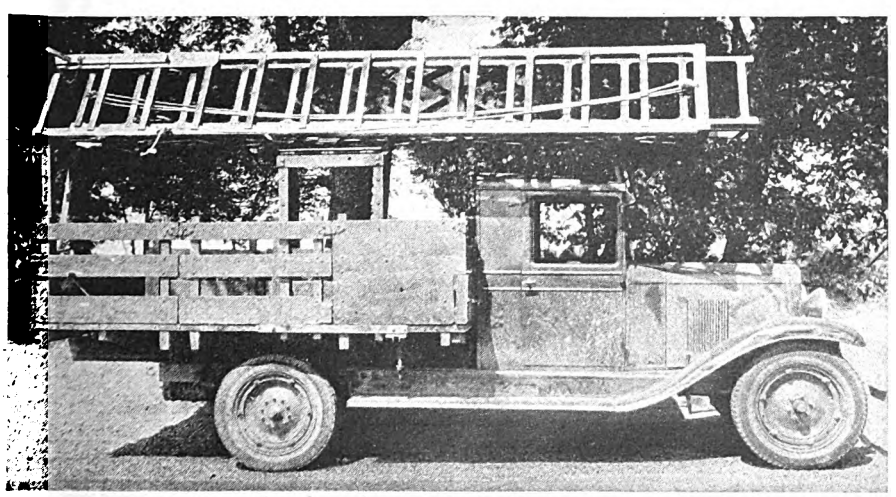


Light-weight convenient tower ladder developed for use on motor trucks

Triangular Tower Ladder

FOR light work of various kinds, a triangular tower ladder has been developed by J. R. McCardell & Company, Trenton, N. J. It has been designed for use with a small motor truck equipped with a steel supporting frame.

The ladder is placed erect at the side of the truck body, and is held firmly in position by the supporting frame and a resting leg attached to the outside post. The length of the resting leg can be adjusted to obtain a solid support. With an outside dimension of 26 in., the ladder weighs approximately 250 lb., and attains a height of 25 ft. from the ground to the platform. The outside section is equipped with 1½-in. steel rollers running in grooves of the inside section, which is raised and lowered by means of a block and fall with ½-in. rope. The ladder can be detached from the frame by removal of a pin.

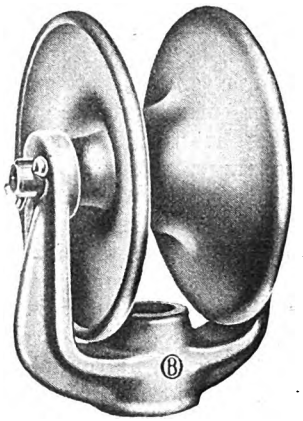


Telescoped sections of the ladder are easily carried on small motor truck

Cable Roller for Stringing Feeder Wire

DAMAGE to feeder wire brought about by contact with crossarms during stringing is avoided by the use of a feeder cable roller, a new product of the Ohio Brass Company, Mansfield, Ohio. In this device attention has been paid particularly to ease of application and substantial construction. The yoke of the roller is provided with a hole tapered to correspond with the threaded portion of a standard insulator pin, over which it is slipped while in use. By this means, no special attachments are necessary. All parts are made of Flecto malleable iron, hot-dip galvanized, with the exception of the ¾-in. hardened-steel axle. The wheel has an over-all diameter of 6½ in.

In operation, the roller is placed on a pole crossarm pin and the wire is fed over it from one crossarm to another for as long a distance as may be desired. The wire is then lifted from the roller, which is removed from the pin, and the insulator installed. The rollers are then moved ahead on the job and the operation repeated. They are made to give long service, and accommodate all sizes and weights of feeder wire.



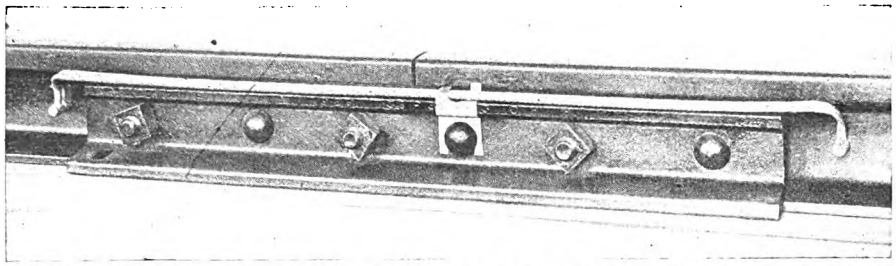
Cable roller for crossarm facilitates stringing feeder wire

Combination Steel and Copper Rail Bond

OWING to the success obtained with strand steel bonds for automatic block signal circuits on the Pennsylvania Railroad, it was decided to determine if the signal bond, or a modification of it, would be adequate for the propulsion current for the 11,000-volt single-phase alternating current system used on that property. The American Steel & Wire Company made numerous experiments and finally developed a bond conductor which proved suitable.

It was necessary to develop a bond which would carry safely 400 amp. at 25 cycles without undue heating. It was also necessary to develop a bond having a relatively low a.c.-d.c. resistance ratio. Experiments were conducted with so-called mixed strands having different arrangements of copper and steel wires. In carrying out this work, it was not only essential to satisfy the alternating

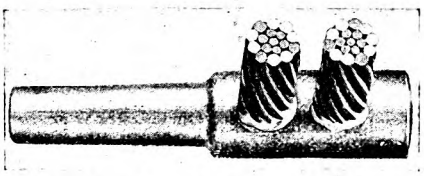
Digitized by Google



Rail bond especially designed for 11,000-volt single-phase a.c. railroad electrification

current impedance characteristics and current carrying capacity, but to develop a bond conductor which possessed the proper mechanical strength, and which was relatively inexpensive.

The bond, as finally developed, is quite simple and has two strands, each having ten copper and seven steel wires, arranged as shown in an accompanying illustration. Terminals are of soft steel and are tapered to make a drive fit into $\frac{3}{8}$-in. holes in the rail web. The terminal is the same as for signal bonds which are very widely used throughout the country. The two strands are flash butt welded to the terminals simultaneously. This weld is very strong and the heat of welding is so localized that the strand is not affected thereby.

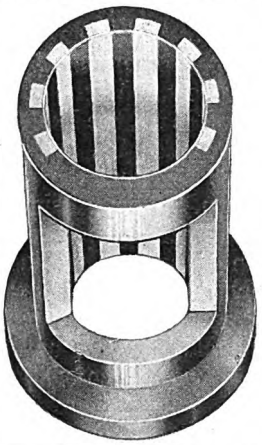


The bond consists of two strands each having ten copper and seven steel wires, arranged with seven copper wires in the center and three copper and all the steel wires on the outside

In order to give the bond an appearance of all steel, the steel wires are galvanized and the copper wires are tinned. The construction of the bond with two parallel conductors serves two purposes: the alternating current carrying capacity is increased over what it would be with a single conductor of cross-section twice the size; in case of failure from fatigue or outside mechanical injury, the likelihood of both strands breaking simultaneously is remote. As the bond is completely exposed for inspection, partial failures can be detected readily.

The bonds were put under laboratory test where it was found that 72 deg. C. rise in temperature resulted from a load of 400 amp. at 25 cycles. In the test piece terminal pins were driven into two pieces of rail.

Bimetallic Armature Bearing

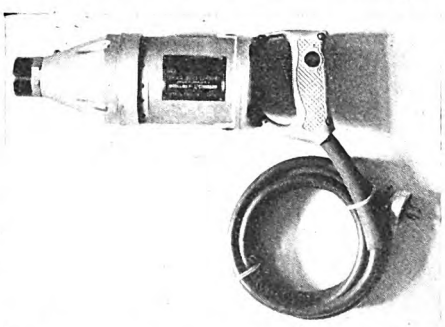


In this type bearing the contact surface is a combination of bronze and lead base babbit strips

REDUCTION in the amount of babbitt metal required is an advantage claimed for a new bimetallic armature bearing developed by the National Bearing Metals Corporation. In this bearing, eight slots have been cut in the bronze parallel to the axis of the armature shaft, thus giving a combination contact of bronze and lead base babbitt metal. During tests of these bearings, 160,000 miles of service was obtained without serious wear on the bearing.

Portable Electric Hand Tool

A SINGLE power unit arranged to drive a variety of hand tools has been developed by the J. G. Brill Company. This new device is known as the Brill Multi-tool. It weighs only $5\frac{1}{4}$ lb., and particularly lends itself to convenient storage of attachments. It is specially adapted to the transportation field. More than fifteen major operations and almost unlimited minor functions can be accomplished by the use of this one power unit. These include drilling, grinding, buffing, sanding, sawing, nut setting, screw driving, planing, filing, valve grinding, reaming, under cutting, nibbling, shearing and mixing.

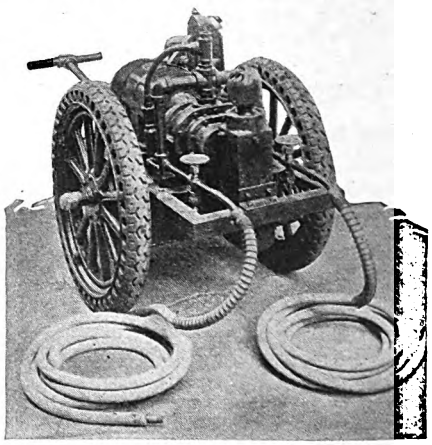


Electric tool adaptable for many uses weighs only $5\frac{1}{4}$ lb.

In the automotive field this tool, in addition to valve grinding and carbon removing, can also be used for body cleaning and polishing, tire and battery repairing, and metal polishing.

Rail Preheater Made More Compact

GREATER compactness, lightness and suitability for joint maintenance are features of a rail preheater developed by the Metal & Thermit Corporation. Either kerosene or gasoline is used as fuel. This is mixed with air from a positive pressure blower driven directly by a motor. Its air intake is through a rotating air filter or strainer located high enough above the ground to avoid the dust and grit always found around construction work. The fuel tank is of ample capacity and is underslung beneath the chassis which is mounted on Ford cushion-tire wheels.



Compact preheater for making Thermit joints

This machine is built in two models. One uses a 550-volt d.c. motor. The other is driven by a 220-volt d.c. motor connected in series with standard space heaters which thoroughly warm the incoming air. It is stated that this gives more economical operation, as it is easier to maintain the fuel in suspension in the preheated air.

NEWS *of the Industry*

LATE NEWS

East St. Louis, Ill. — The Illinois Commerce Commission on July 23 took under advisement the application of the East St. Louis Railway for a straight 10-cent fare instead of 10 cents for single fares and five tokens for 40 cents. Prior to the conclusion of taking the evidence, the commission overruled a motion by counsel for the city for a reappraisal of the company's properties.

✦

Phoenix, Ariz.—At a meeting of the Council on July 14, it was decided to increase the fare on the municipal railway from 5 cents to 7 cents cash with four tokens for 25 cents for adults. School fares will be twenty for $1.

✦

San Diego, Cal.—At a recent meeting of delegates of the League of California Municipalities, a committee of the members was appointed, at the suggestion of Commissioner W. J. Carr of the California Railroad Commission, to develop a plan for assisting the cities, and supporting the railroad commission in the work of regulating the public utilities of the state.

✦

Jamestown, N. Y. — The Celoron Amusement Company, owned by the Jamestown Street Railway, which has operated an amusement park 5 miles from here on Lake Chautauqua, has been sold for $400,000, to Thomas and George Carr, managers of the park for the past ten years. The park was established 25 years ago by the late A. N. Broadhead, head of the railway, to promote business on its Celoron-Jamestown line.

✦

Los Angeles, Cal.—Five more single-deck, 29-passenger coaches are being delivered to the Los Angeles Railway to be added to the 2,300 series. These coaches are generally similar to the other rear-door equipment recently delivered, but are the first single-deckers to have single-sash drop plate glass windows.

✦

Rochester, N. Y.—In an endeavor to remedy abuses of the transfer privilege, the New York State Railways, Rochester lines, has put into use a new transfer to be issued to passengers only on request and at the time of paying fare, expect in emergency cases where cars are turned back. In such cases special emergency transfers will be issued.

✦

Quebec, Que. — As the result of an order from the railway commissioners, the Quebec Power Company is authorized to extend its street car service in St. François d'Assise and Charlesbourg, as far as the city limits. At present the track runs only as far as the new Canadian National Railway tunnel, but the extension is expected to be completed and in operation by the start of next winter.

(Late News Continued on Page 542)

Terminable Permit Suggested at St. Louis

Transportation Survey Committee Recommends Co-ordination With Liberal Subway Construction Program. Need for New Street Cars Stressed

THE Transportation Survey Commission of St. Louis, Mo., made its final report to the Board of Aldermen on July 25. Among other things it suggested that the St. Louis Public Service Company be granted a terminable permit for 50 years, thus giving the city the largest measure of home rule in the regulation of its railway and bus rates obtainable under the present city charter.

In its report the commission also favored co-ordination of cars and buses, ultimate elimination of parking downtown and in other congested districts, restrictions on service car operations, construction of a subway under Olive Street between Third and Nineteenth Streets to cost about $10,000,000, the rerouting of various railway lines, construction of traffic signals and safety zones at various points, completion of the street widening program prepared by the City Plan Commission and the elimination of 530 little-used street car stops on various lines.

The report recommends the adoption of the comprehensive plan of subway construction suggested by the Kinsey Commission in 1926, such construction to be undertaken when the city's growth demands these improvements. The subways suggested by the Kinsey Commission would cost approximately $240,000,000.

In his report on rapid transit R. F. Kelker, Jr., who was consulting engineer for the Transportation Survey Commission, contended that St. Louis is not ready for subways and that the existing surface street car lines can be developed to meet the city's transportation needs for years to come.

Stressing the necessity of new street cars, bus service extensions, rerouting of car lines and additional power facilities, the commission suggests that the Aldermen move to make it possible for the company to borrow $23,760,000 to carry through a five-year program of expenditures for new cars and betterments.

Two alternative plans of new permits for the railway are suggested:

1. A terminable permit for 50 years and providing home rule by securing necessary enabling legislation at the next session of the Missouri General Assemby to create a St. Louis Transit Commission having full power over local utilities, now vested in the Missouri Public Service Commission.
2. A contract with the railway in which it would agree to unify all mass transportation, and the city agree to acquire ownership of the properties through a share in the receipts from operation. In this connection the commission recommends that when the city obtains ownership of the transportation system it arrange for a lease for private operation.

Walter J. G. Neun, president of the Board of Aldermen, and Edward L. Kuhs, Aldermen from the First Ward, members of the commission, dissented from the recommendation for a terminable permit.

The Business Outlook

EXACTLY a year after business scaled the peak of its 1929 boom it is reaching its low in the subsequent depression. As we move further into the last half the paralyzing pessimism of recent months will find less to feed on in the comparative records of this year and last. While general trade is beginning to sag under the pressure of months of impaired confidence, industrial activity and railroad movement show signs of revival under the stimulus of depleted stocks, and non-agricultural commodity prices are strengthening. At this crucial point, emergency Farm Board support of farm prices against the weight of temporary crop surpluses, and further Federal Reserve support of the bond market are vitally necessary. This is the decisive round in the contest with the forces of deflation.—*The Business Week.*

Start Made on Chicago Subway Plans

Plans for Chicago's subway progressed apace when the first meeting of all concerned on actual subway construction since the approval of the transportation ordinance was held on July 23 in the office of Walter L. Fisher, attorney for the local transportation committee of the Council. The removal of pipes, wires, conduits, vaults and other property of the public utilities in State Street preparatory to digging the subway was discussed, but no decisions were made.

Engineers state that their plans have progressed to a point where it will soon be necessary to know what utilities wish to use the galleries to be provided for them in the subways, and which positions they prefer.

The "L" has filed condemnation proceedings against the property of 203 Chicago owners. It hopes in this way to procure the remaining property necessary for the widening of its Garfield Park branch between Marshfield and Laramie Avenues. Much of the necessary property has already been obtained by private purchase. This proposed improvement will be the first started under the terms of the recent franchise grant.

Electrification Prospects at Chicago

Definite action in Chicago's efforts to have its railroad terminals electrified is gradually approaching. The chairman of the City Council railway terminals committee, said recently:

"This committee has not yet given up hope of obtaining agreement of the railroads to a unified terminal and electrification of lines within the city. We are holding meetings weekly and are hopeful of results. However, if the railroads refuse to co-operate, the city will file a certificate of public convenience and necessity before the Commerce Commission citing the public need for electrification.

"So far the railroads have continued to declare that their revenues have decreased to such an extent that they are unable to electrify. They have stated that they have no prospect of much improvement within the next 25 years because of the increasing competition in passenger service from the automobile and airplane."

Rochester-Buffalo Coach Order Modified

The Public Service Commission has amended its order granting the Rochester, Niagara Falls & Buffalo Coach Lines, Inc., permission to operate a bus line between Rochester and Buffalo, by way of Lockport, N. Y. The modified order permits operation of buses only from Rochester to Lockport, where transfer must be made to the International Railway to Buffalo.

The coach company may renew its petition for a bus line through to Buffalo at the end of a six-months' period. It was planned to supplant the present Rochester, Lockport & Buffalo electric interurban line with buses. The officers of the coach company are the same as those of the electric railway.

Segregation Planned at Portland, Ore.

To facilitate compliance with a recent order of the Oregon Public Service Commission that the power and the railway businesses of the Pacific Northwest Public Service Company, Portland, be kept entirely separate, the company proposes to form two subsidiaries for administrative purposes. Under the plan proposed, the Portland General Electric Company will be formed to take over the physical property and franchises covering the power and light and interurban railway operations, and the Portland Traction Company to take the local railway property and franchises. The formation of the new companies has no interest at the present time for investors since the parent Pacific Northwest Public Service Company will become the sole owner.

747 Graduates of Chicago First Aid Classes

The Britton I. Budd Medal for the Saving of Human Life was awarded to two employees of the Chicago Rapid Transit Company, one employee of the Chicago, North Shore & Milwaukee Railroad, and one employee of the Chicago, Aurora & Elgin Railroad recently at the eighth annual first aid and safety banquet of the associated electric railway and motor coach lines serving the Chicago metropolitan area. Presentations of the medals were made by Mr. Budd, president of the companies, who instituted the award in 1926 as a fitting recognition for any employee who succeeds in saving the life of anybody, anywhere and at any time. These awards made a total of 21 employees of the various transportation lines who have saved human lives as a result of first aid training under the direction of the medical department, headed by Dr. Hart E. Fisher, chief surgeon. The banquet marked new records in first aid training of employees in these transportation companies, with a total of 747 receiving diplomas as compared with 558 last year.

Many Interesting Bus Topics on Pittsburgh Program

More than 1,000 traffic men and engineers, motor truck and motor coach operators are expected to attend the annual National Transportation Meeting of the Society of Automotive Engineers to be held in Pittsburgh, Oct. 22, 23 and 24. The Pittsburgh Section, under the direction of Chairman J. M. Orr, is making arrangements for the dinner and will conduct the affair. For the technical sessions the following speakers and topics have been selected and scheduled:

C. W. Stocks, editor of *Bus Transportation*, "Requirements for Performance-Indicating and Recording Devices, Their Installation and Operation."

H. B. Hewitt, of the Philadelphia Rural Transit Company, "Scientific Inspection of Motor-Vehicles and Their Units."

P. V. C. See, of the Northern Ohio Light & Power Company, "Motor-Vehicle Maintenance Methods to Prevent Delays."

Austin M. Wolf, consulting automotive engineer, "Practical Mathematics for Determining Tractive Ability."

Adrian Hughes, Jr., of the United Railways & Electric Company, Baltimore, "How Advantage Can Be Taken of the Latent Heat of Cooling Water."

James W. Trimmer, of the Carnegie Institute of Technology, "How the Principles of Economics in Motor-Vehicle Transportation Are Taught by Educational Institutions."

The paper by Professor Trimmer will be supplemented by prepared discussion by J. S. Lowe, of the Northern Ohio Light & Power Company, describing the school of training established by that company for its motor coach operators. Frank D. Coll, of the Aluminum Company of America, will present a paper describing the use of aluminum alloys in commercial motor-vehicles.

Canadians Announce Program for Ottawa Meeting

The tentative program has been announced for the papers and timely topics to be presented at the 26th annual convention of the Canadian Electric Railway Association at Ottawa on Sept. 18, 19 and 20. The program follows:

WEDNESDAY, SEPT. 17, 1930

Timely Topics — "The Effect of Traffic Lights on Street Car Operation," by D. E. Blair, general superintendent Montreal Tramways, and W. F. Irvin, traffic study engineer Toronto Transportation Commission.

THURSDAY, SEPT. 18, 1930

Paper — "The Trolley Bus," by E. A. West, general manager Utah Light & Traction Company.

Discussion led by Fred E. Dayes, chief engineer A.C.F. Motors Company, and Ross Schram, vice-president Twin Coach Corporation.

Timely Topics—"Fire Protection—Methods Used to Reduce Fire Hazards and Decrease Insurance Premiums," by J. C. L. Ryan, engineer and rating expert Johnson & Higgins, Ltd., Montreal, P. Q., and W. E. P. Duncan, engineer of structures Toronto Transportation Commission.

"Operating Features of Cars Recently Purchased by Canadian Electric Railways," by A. M. Lindsay, superintendent of rolling stock Montreal Tramways, and representative of British Columbia Electric Railway.

FRIDAY, SEPT. 19, 1930

Paper—"Street Railway Fares," by Prof. Albert S. Richey.

Discussion led by J. B. Hayes, manager Nova Scotia Light & Power Company, Ltd.

Timely Topics—"Welding as Applied to Track Maintenance," by W. A. MacRae, engineer of way Toronto Transportation Commission, and J. G. McCarty, manager Metal & Thermit Corporation, Toronto.

"Bus Inspection Methods," by H. R. Holder, superintendent of autobus department Montreal Tramways, and M. D. Mills, experimental engineer Motor Coach Division General Motors Truck Company.

Trouble Shooters of the Rochester Railway and Bus Lines Being Dispatched by President Tilton

LATE NEWS

(Continued from Page 540)

Washington, D. C.—One-man street cars will be installed on the Mount Vernon, Alexandria & Washington Railway on Aug. 15 if the Public Utilities Commission grants the plea of the railway asking permission for the change.

✦

New York, N. Y.—Representatives of the Board of Transportation are engaged in the work of getting written consent of property owners on the proposed subway route along Worth Street, East Broadway and Grand Street, from Church Street to Lewis Street, a project approved by the Board of Estimate recently.

✦

Chicago, Ill. — The receivers for the Chicago Railways were ordered by the United States District Court of Northern Illinois to pay regular semi-annual interest and 5 per cent on principal amount of the first mortgage bonds of the company on Aug. 1, 1930. Last year 10 per cent of the principal amount of these bonds was paid by order of the court and interest has been regularly paid since the bonds defaulted in principal in 1927.

✦

Pittsburgh, Pa. — Trainmen of the Pittsburgh Railways have defeated a proposal that they work on a six-day instead of seven-day schedule to save the jobs of 300 now on the "extra list" or soon to be there.

✦

Fort Wayne, Ind. — Arrangements have been made for the hearing of evidence on the petition of the Indiana Service Corporation for authority to increase the price of a single cash fare from 7 cents to 10 cents and the price of four tokens from 25 cents to 30 cents. The company will continue to sell its weekly pass for $1. The corporation announced about a year ago, when it granted an increase in wages, that it would ask an increase in fares. Its officials maintain that its rate of return has fallen off since 1926 and that it cannot maintain efficient service and extend its service without the petitioned increase.

✦

Holyoke, Mass.—Early installation of the one-man system of operation by the Holyoke Street Railway is forecast. Directors have agreed to authorize the manager to put the plan in force at such time as he deemed necessary.

✦

Atlanta, Ga.—The Georgia Supreme Court has upheld the right of the State Public Service Commission to regulate motor carriers. In a decision rendered on July 26, the state's highest tribunal declared the Fulton Superior Court in error in granting an injunction to the Saye M. Davis Transfer Company to prevent regulation. The Supreme Court held that the motor carrier act of Georgia was not unconstitutional, as declared by the petitioner, and that it was unnecessary to determine whether a carrier was a private or common servant.

✦

Grays Harbor, Wash.—More than 5,000 youngsters and parents of Grays Harbor County consumed 750 gal. of ice cream and 23,000 cones at the Fourth Annual Kids Party held at Electric Park, Aberdeen, Wash., by the Grays Harbor Railway & Light Company in July. The announcement of this year's party was one of the first official acts of J. R. Snider, newly elected general manager of the company, to allay the juvenile fears that the party might be discontinued because of the death of its founder, Wallace W. Briggs. A feature of the party was the dedication of an ornamental fountain carrying the following inscription: "Wally Briggs Swimming Hole, built for the boys and girls of Grays Harbor, and dedicated to their happiness by Wallace Wheaton Briggs, general manager, 1929."

✦

Baltimore, Md.—William McCallister, president of the Hamilton Improvement Association, has suggested to the United Railways & Electric Company a bus line to connect the Harford and Belair roads, providing a more direct route from that section of the city to the southeastern section. It is urged that the route follow the new Echodale Boulevard, which is to be built.

✦

Staunton, Va.—The City Council has directed City Manager Day to transmit to officials of the Shenandoah Traction Company at Pittsburgh an approved draft of a franchise for operation of a bus service here in place of the existing railway. As the draft has the approval of the city attorney and attorneys for the new company, the action is regarded as practically the final step in agreement on a bus franchise. The final franchise draft provides for a fare not more than 10 cents, subject to revision within five years to "not less than 5 cents." The grant is to run for 15 years.

✦

Rochester, N. Y.—An order for discontinuance of the Rochester & Eastern Railway, was signed on July 26 by Judge Simon L. Adler in Federal court, on the application of receivers for the New York State Railways. It was made effective at midnight July 31. Seven communities on the route will be left without transportion. Other parts of the line are being served by a bus line with headquarters in Syracuse.

✦

High Point, N. C.—Members of the City Council will submit a plan to officials of the North Carolina Public Service Company calling for the operation of buses here instead of street cars, and giving the company the right to remove all trackage that is not needed by the High Point, Thomasville & Denton Railroad for car shifting purposes.

They Saw It in the News

A 17-LINE ride-selling item in ELECTRIC RAILWAY JOURNAL NEWS for May 31 has provoked inquiries to the company mentioned from Pittsburgh, Binghamton, Los Angeles, Des Moines, Seattle, Tacoma and other cities for further details. This is typical. If you are not reading ELECTRIC RAILWAY JOURNAL NEWS, you are missing a service designed especially to keep you well-informed on current events. And current events are the materials that make history!

Cleveland, Ohio.—The charge that the Cleveland Interurban Railroad, which operates the Van Sweringens' Shaker Heights rapid transit line, violated the Ohio utilities regulations when it increased the fare from 10 to 15 cents has been made in a petition filed with the Ohio Utilities Commission.

✦

Washington, D. C. — Revaluation of the local railways based on a physical inventory of their used and useful property has been asked of the Public Utilities Commission by Richmond B. Keech, people's counsel. The revaluation is asked to establish a new basis for fixing rates, in an effort to bring about a reduction in the 10-cent cash fare, with four tokens for 30 cents, recently granted by Justice Jennings Bailey, of the District Supreme Court. Mr. Keech contends that radical changes have taken place in prices and equipment since the physical inventory of 1914.

✦

St. Augustine, Fla.—Service by bus has been substituted for the trolley line to St. Augustine Beach run by the Florida Power & Light Company.

✦

Richmond, Cal.—The Key System Transit Company has applied to the California Railroad Commission for an order permitting the operation of a bus line here in accordance with a permit granted by the City Council.

✦

St. Louis, Mo.—Counsel for the St. Louis Public Service Company on July 28 asked the Public Service Commission to dismiss the protests against the rerouting of cars on the Fourth Tower Grove, Compton and Bellefontaine lines. The company points out that it cannot furnish a "door-to-door service to its patrons," and that the line was rerouted in the interest of the general good of patrons and of economy in operation.

✦

Chicago, Ill.—Federal Judge Wilkerson entered a decree on July 23 fixing the amount and priority of liens against the Chicago City Railway and the Calumet & South Chicago Railway. Receivership proceedings have been continued until Sept. 25, after which date an order of sale will probably be entered.

✦

Jamestown, N. Y.—Work of removing the tracks of the Warren & Jamestown Street Railway in this city is under way. The company abandoned service between Warren, Pa., and Jamestown, N. Y., Dec. 1, 1929, and the removal of tracks marks the termination of the line.

✦

Venice, Ill.—Preliminary steps have been taken toward the construction of an 800-ft. reinforced concrete viaduct to carry Broadway here, over the tracks of the Terminal Railroad Association and other railroads. The estimated cost of the project is $500,000. The Terminal Railroad Association of St. Louis, the Illinois Terminal Railroad and the city of Venice would share the cost.

✦

Raymond, Wash.—The Willapa Electric Company has replaced operation of its railway system in the South Bend-Raymond district with buses. Workmen are removing the tracks through Raymond to speed up paving of the state highway which is to form an important link in the Ocean Beach route.

Amicable Settlement of Niagara Falls Case Arranged

The Public Service Commission on July 29 approved the operation of buses by the International Railway on Hyde Park Boulevard and other streets in Niagara Falls to supplement its trolley service. The line will be established only if the International Railway's petition for an 8-cent fare is granted.

The order of the commission approves a franchise granted to the International Railway by the City of Niagara Falls for the operation of buses over streets extending northward through a comparatively new section of the city and looping at the southeast through an older part of the city. The new line is about 4 miles long.

The proposed bus line is to provide needed additional service for employees of industrial plants at the northern end of the route and at the loop over which the buses are to be turned at the southern end of the route. Buses are to be operated on a 30-minute headway during the day, except that, during the morning and evening rush periods service will be maintained on a 15 minute headway. A 10-cent fare is to be charged and transfers will be given from buses to connecting trolleys and from trolleys to buses upon payment of a 10-cent fare on the trolley cars.

The city of Niagara Falls favored the establishment of the proposed bus line and no opposition was expressed to the application. In a memorandum written by Commissioner Maurice C. Burritt, and approved by the commission, it was stated that "it appears that approval of the petition is in the public interest and that it will add to the convenience of the people of Niagara Falls in traveling over the streets of the city and in supplementing the present street car system."

City Agreeable

Without waiting for its new schedule of increased fares to be approved by the Public Service Commission, the International Railway decided immediately to improve service in Niagara Falls, N. Y., by inaugurating a system of more frequent service on every line in the city and by starting the work of improving and renovating its rolling stock.

Application has been made to the Public Service Commission by the company for approval of the schedule of increased fares granted the company by resolution of the City Council, meeting on March 17.

The agreement entered into between the company and the City Council grants the company a trolley fare of 8 cents a passenger on local lines; or sale of two tickets or tokens for 15 cents, and grants an increase from $1 to $1.50 on sale of commutation books of 20 tickets each between the old village of La Salle and Niagara Falls with transfer privileges to or from local lines in Niagara Falls, but commutation tickets will not be accepted as part payment for a through fare.

The railway promptly issued a statement to the effect that in appreciation for the "splendid spirit of fair dealing" that the people of the city have displayed in the settlement of the fare controversy it "has decided to do even more than it promised."

The whole matter is a lesson in good public relations not easy to match. Not only did the proposal meet with hearty approval by the public, but the attitude of the local newspapers, particularly the Niagara Falls *Gazette*, was most helpful. Evidently baiting big business has no zest for the local papers. On various occasions the *Gazette* put the matter this way:

"No contract that is confiscatory is binding. Niagara Falls does not want to take advantage of such a contract, if expressions of the people are to be accepted as indicating public sentiment.

"The Buffalo *Evening News* sees in the Niagara Falls situation a rare opportunity for this community to wallop the traction company, but fortunately we do not treat our business interests that way."

"The increase asked by the company is very reasonable, and its consent to abide by this figure for a term of at least ten years is an earnest of its good faith. The *Gazette* feels that the City Council has performed a good stroke of business for Niagara Falls. The increase in fares was inevitable, and by arriving at this very satisfactory settlement of the matter the city is saved a large sum of money in lawyers' fees, expert hire, and other costly incidentals that usually feature litigations in cases of this character."

Congestion Greatest Economic Problem Before the Cities

H. M. Patton, district superintendent of the Union Electric Light & Power Company, St. Louis, Mo., was elected president of the Missouri Association of Public Utilities at the recent meeting of that body to succeed Major T. J. Strickler, Kansas City. The election took place at the closing session of the three-day convention of the association which was attended by 200 delegates from various parts of the state.

A feature of the convention was the address of Milton R. Stahl, chairman of the Missouri Public Service Commission, in which he advocated a broadening of the powers of the commission to give it jurisdiction over holding companies for local public utilities and supervision over the sale in Missouri of stock in holding companies.

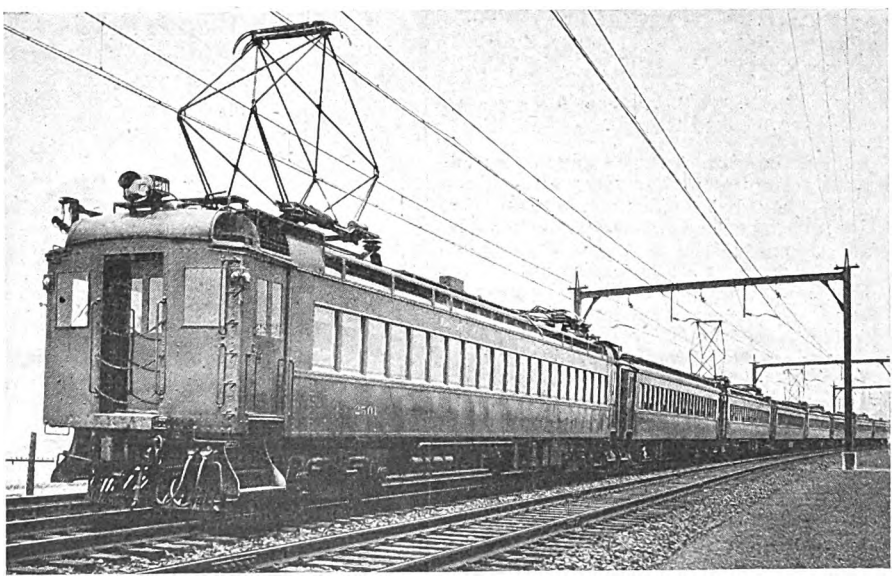
Better use of existing street facilities would solve many of the traffic problems of large cities, Charles Gordon, managing director of the American Electric Railway Association, asserted in his address. He expressed the belief that existing thoroughfares should be used to their fullest extent rather than for a city to indulge in expensive street widening and expansion program.

He brought out that acute street traffic problems are manifest in all of the major cities and in many of the small cities and towns as well. He said that congestion of streets has become perhaps the greatest single economic problem confronting modern cities and that it is already having a profound effect upon the business and social life and is threatening to bring about major readjustments of property values and business locations, particularly in the central business districts.

Lackawanna Plans Electric Suburban Service Sept. 15

Electric service probably will be started by the Delaware, Lackawanna & Western Railroad on the Montclair division about Sept. 15. One electric train at a time will be substituted for a steam train in the regular schedule. Operation and performance will be watched carefully and if any difficulties arise they will be ironed out before the next train is put into service. Subsequent substitutions will be made train for train until full electric service is in operation. Meanwhile, four engineers are receiving instruction on the new equipment daily. To the end that service may be begun as scheduled, the first of the new multiple-unit trains was operated at 4 p.m., on July 17. Since that time four-car and eight-car trains have been run daily between Bergen Junction and Secaucus, N. J., to test equipment and instruct trainmen. Runs have also been made along the main line from Bergen Junction to Harrison Tower.

Substation equipment is being installed according to schedule. Buildings are completed and electrical apparatus is approximately 50 per cent in place. New cars are arriving and trailers are being converted at the rate of one a day and will continue on that schedule until the completion of 141 units, each consisting of motor car and trailer.



Train Being Used for Tests on Lackawanna's New Electric Zone

Companies in Suburban New York Seek Fare Increase

The Yonkers Railroad, the Westchester Electric Railroad, and the New York, Westchester & Connecticut Traction Company, on July 30, petitioned the Public Service Commission for permission to increase their fares from 5 to 8 cents in Yonkers, Mount Vernon and other portions of Westchester County.

The petitions of all companies stated that the present rate of 5 cents does not provide a fair return on their investments and that the proposed 8-cent fare will constitute no more than a just and reasonable rate.

The Yonkers Railroad desires to charge 8 cents for rides in the city of Yonkers and in Mount Vernon where it has a line also, and to increase the fare to 8 cents in every instance where a 5-cent fare is now collected. The company states that in 1929 its revenue was $1,284,598, and that this fell short by at least $390,000 of meeting the operating expenses of the company, and that it fell short by about $325,000 of yielding a 7 per cent return.

The Westchester Electric Railroad desires to charge 8 cents instead of 5 cents for rides in the city of Mount Vernon, the villages of Pelham, Pelham Manor and North Pelham and between points where a 5-cent fare is now charged. The petition does not ask an increase for rides originating and terminating within the city of New York. This company states that its 1929 revenue of $785,349 fell short of meeting operating expenses by at least $355,000 and of yielding a 7 per cent return by at least $309,000.

The Westchester & Connecticut Traction Company desires to charge 8 cents for rides in Mount Vernon and North Pelham and between other points where a 5-cent fare is now collected. This company states that its 1929 revenue of $83,160 fell short by at least $32,500 of meeting expenses, and that it fell short by at least $28,000 of yielding a 7 per cent return to the company on its investment and property value.

Trolleys Speeded by New York's New Stagger System

The co-ordinated "stagger" traffic light system went into effect throughout Manhattan at 7 o'clock on the morning of July 30. Control mechanisms were adjusted after the light control stopped for the night at 3 a.m. and when it went into operation again the light changes were so timed that north-and-south traffic flowed uninterruptedly for about a minute and a half, instead of two minutes as formerly and east-and-west traffic ran for about 30 seconds, instead of one minute.

To speed the movement of traffic in the Times Square district, the light tower at 45th Street was removed. This was the point from which Commissioner Whalen last year observed the results of the traffic regulations he put into effect for the theatrical district. It has stood in front of the Hotel Astor for seven years.

Changing the light mechanism to "stagger" the traffic was a simple matter of setting disks in the central control towers to revolve at constant speed with the signal systems for the various avenues and streets. Readjustments were made at the central control room in the West 30th Street station and at the auxiliary control room in the West 126th Street station.

Police Commissioner Mulrooney had observers stationed in many parts of the city. He reported gains in speed from 15 to 50 per cent. William G. Fullen, chairman of the Transit Commission, who had inspectors on the job, had a table of data showing one gain of as high as ten minutes from westbound trolley traffic on 34th Street. The Third Avenue Railways reported a 33 per cent gain in speed on the 42nd Street line, with other gains on different lines.

All reports contained assurances as well that while crosstown traffic had been speeded the gains had not been effected at the expense of the longitudinal vehicular flow. Most of the reports said that there had been some speeding up of north-and-south traffic, although to a considerably lesser degree.

William Thompson, vice-president of the Third Avenue Railway, said:

> The new system has resulted in a material increase in speed on our crosstown lines without any retarding of north-and-south traffic. In fact we have received reports of some light gains in north-and-south traffic. On the 42nd Street crosstown line the speed gain was about 33 per cent, on the 59th Street line about 19 per cent and on the 125th Street line about 15 per cent.

At the offices of the New York Railways it was announced that the crosstown trolley car movement had shown definite gains in speed, although data had not been compiled to show the actual gains. This statement also emphasized that north-and-south traffic had not been impeded.

Officials of the Fifth Avenue Coach Company said they were still checking their data, but that a preliminary survey had indicated gains in the operation of their buses.

Indiana Railroad Succeeds to Union Traction Properties

INDIANA Railroad is the new name under which the electric interurban lines of the old Union Traction Company of Indiana began operating on Aug. 1.

Properties of the Union Traction Company, which were purchased at a receiver's sale in Anderson on July 2 by B. P. Shearon, secretary of the Midland United Company, have been conveyed by order of the Madison Circuit Court to the Indiana Railroad, which is a subsidiary of the Midland United Company.

The full amount of the purchase price, $3,923,933, including $376,528 in cash and the rest in bonds and other securities, was paid to Arthur W. Brady, the receiver, by the Midland United Company on July 17. The new owners, however, will not assume full control of the properties until Mr. Brady makes his final report to the court and relinquishes the receivership, probably the latter part of August.

Operation of the Indiana Railroad will be under the direction of Henry Bucher, vice-president of the Indiana Service Corporation. Mr. Bucher is the managing executive of the railway department, through which the operation of other electric railways in central and southern Indiana controlled by the Midland United Company is now co-ordinated.

The electric interurban lines, which will be operated under the direction of one centralized supervisory management at Indianapolis, include the line between Indianapolis and Louisville operated by the Interstate Public Service Company, the lines of the Indiana Service Corporation radiating from Fort Wayne, the line of the Northern Indiana Power Company extending from Frankfort to Kokomo and Marion, and the old Union Traction Company which now becomes the Indiana Railroad.

Co-ordination of service and schedules, which it is believed will be of benefit to the traveling public, is expected to be one of the results of the centralized control of operations of these railways.

The board of directors of the new Indiana Railroad elected the following officers at a meeting held in Chicago, on July 30:

Samuel Insull, chairman of the company.
Samuel Insull, Jr., chairman of the executive committee.
Robert M. Feustel, president.
William A. Sauer, vice-president.
Henry Bucher, vice-president and general manager.
George F. Mitchell, treasurer.
Bernard P. Shearon, secretary.
Edwin J. Booth, comptroller.

The directors of the company are: Mr. Insull, Mr. Insull, Jr., Mr. Feustel, Mr. Sauer, Mr. Bucher, Charles W. Chase and L. M. Brown.

COMING MEETINGS

Aug. 13-14—Wisconsin Utilities Association, Milwaukee, Wis.

Aug. 14—American Electric Railway Assn., Metropolitan Section, Sixth Annual Outing, Luna Park, Coney Island, N. Y.

Sept. 5-6 — Central Electric Traffic Association, Wawasee, Ind.

Sept. 10-11—Central Electric Railway Master Mechanics' Association, Miami Hotel, Dayton, O.

Sept. 17-19 — Canadian Electric Railway Association, 26th annual convention, Ottawa, Canada.

Sept. 25—Pennsylvania Street Railway Association, Casey Hotel, Scranton, Pa.

Oct. 9-11—Midwest Electric Railway Association, Miami, Okla.

Oct. 22-24—National Transportation Meeting of the Society of Automotive Engineers, Pittsburgh, Pa.

Oct. 29-30—Iowa Electric Railway Association, Des Moines, Ia.

Vote on Future of the Boston Elevated Railway

At the state election in November of this year there will be submitted to the registered voters of the cities comprising the so-called Metropolitan District, the following plans for determining the future ownership, management and operation of the Boston Elevated Railway, Boston, Mass., namely:

Plan No. 1. Return to the Boston Elevated Railway of the management and operation of its railway system by terminating public management and operation thereof.

Plan No. 2. Continuation of public management and operation of the Boston Elevated Railway in accordance with such terms and conditions as may be agreed to by the stockholders of said company.

Plan No. 3. Purchase by the Metropolitan Transit District of the whole assets, property and franchises of the Boston Elevated Railway, the same thereafter to be owned, managed and operated by said district.

The referendum will have no legal effect, but will merely inform the succeeding Legislature as to the preferences of a majority of the voters of the Metropolitan Transit District. It will be necessary for the Legislature to enact legislation to put into effect any one of the foregoing plans.

Proposed Abandonment Under Inquiry

Engineers of the Ohio Public Utilities Commission will make a survey of the rolling stock and roadbed of the Scioto Valley Railway & Power Company to aid in determining whether the road should be permitted to abandon railway service between Columbus and Chillicothe and Columbus and Lancaster. At the first hearing, held on July 23, officials of the company testified that $200,000 would have to be expended to place the rolling stock and the roadbed in good condition. They said the company could not finance this program inasmuch as the road now is operating at a loss of $7,000 per month. Residents insist the lines are a necessity and that, under more skillful management, the system could be made profitable.

Question of Jurisdiction in San Diego Hearing

The hearing scheduled to be held by the Railroad Commission in San Diego, Cal., on June 19, in the matter of the application of San Diego Electric Railway to abandon railway operation and remove its tracks in Coronado, substituting therefor through bus service over the ferries of the San Diego & Coronado Ferry Company into San Diego, was continued without taking of testimony as to public convenience and necessity. The application was amended to offer loop bus service in Coronado and continue the railway operation there as a concession to the expressed desire on the part of residents who prefer to transfer from the cars to the upper decks of the ferry boat rather than be shut in on the automobile deck in a bus.

At the hearing the City Attorney and members of the City Council said they had before them the matter of municipal operation with buses to be furnished by a proposed rival bus company on a rental basis, wherein the city was to be guaranteed against any losses for a period of five years. They requested that action on the application of the railway be postponed until they could determine what action they wished to take in the matter. It was also contended that inasmuch as the operation of the proposed bus service was entirely within the limits of Coronado, the commission had no jurisdiction, the railway being subject only to municipal control through franchise requirements. Since there is some question as to proper interpretation of the Public Utilities Act, the commission took the matter under advisement to determine its jurisdiction before hearing is to be continued.

The matter is of interest because of the attempt of private parties to enter into bus competition with established utility under the guise of municipal operation, the private parties obtaining remuneration through tolls received from ferrage of the vehicles across the Bay of San Diego, including tolls for the passengers, by means of a rival ferry company.

A Hitch in Hitch-Hiking

THE practice of "thumbing" for rides has become an annoying business. That it is also extremely dangerous for the good-natured motorist to pick up strangers has been proved in innumerable cases.

Some of these motorists have been murdered by their "pick-ups," and many others have been beaten and robbed of money and cars. Still others have had to defend suits brought for injuries by the thumbers to whom they gave assistance, and on several occasions innocent motorists have become involved with the courts for aiding fugitives, youthful runaways and delinquent girls.

While some states have taken official action to stop ride-begging on their highways, the one way to put a stop to the nuisance is for motorists everywhere to pass the thumbers by. The only persons who can put a real hitch in hitch-hiking are the motorists themselves. Motor clubs could save some of their members much embarrassment and grief, by acquainting them of the dangers they run by picking up strangers on the highways.—*Condensed from the Cincinnati Enquirer.*

A. C. Blinn in Charge of Ohio Edison Operations

Announcement Made of Official Roster of Officers for New Merger Company in Commonwealth & Southern Group Operating in Ohio

OFFICIAL announcement was made, on July 23, of the organization of Ohio Edison Company, created by the consolidation of the Pennsylvania-Ohio Power & Light Company, Northern Ohio Power & Light Company, the Ohio Edison Company, the Akron Steam Heating Company, and the London Light & Power Company. The company will be operated by divisions with the general headquarters in Akron.

A. C. Blinn in Charge

A. C. Blinn, who has been vice-president and general manager of Northern Ohio Power & Light Company for many years, will be vice-president and general manager of the Ohio Edison Company in charge of all the utility operations.

L. G. Tighe, for the last six years assistant general manager of Northern Ohio Power & Light Company in Akron, has been made a vice-president and director of the new company, and will be manager of the Akron division which includes the cities of Akron, Barberton, Cuyahoga Falls, Kent, Tallmadge, Lakemore, Northfield, Brimfield and a large number of other smaller communities.

C. S. MacCalla, formerly vice-president and general manager of the Pennsylvania-Ohio Power & Light Company, is a vice-president and director of Ohio Edison, and will be manager of the Youngstown division, comprising the cities of Youngstown, Girard, Lisbon, Salem, Struthers, Leetonia, Canfield, Columbiana, Kinsman and numerous other towns and communities.

H. E. Miller, former general manager and director of the Ohio Edison Company at Springfield, will be manager of the Springfield division, which includes Springfield, London, Marysville, Urbana, Mechanicsburg, Westville and other communities.

Other officers of the company are: H. G. Kessler, New York, comptroller; P. Murdoch, Akron, general auditor, with H. R. Bowie, Youngstown, assistant; E. G. Dunlap, Youngstown, treasurer; C. H. Lahr, Akron, secretary; L. I. Wells, Akron, E. E. Nelson and C. Wigand, New York, assistant secretaries and assistant treasurers.

B. C. Cobb the President

B. C. Cobb heads the new company as president and chairman of the board of directors. Other directors are A. F. Ayers, Akron; W. H. Barthold, New York; A. C. Blinn, Akron; W. H. Foster, Youngstown; H. E. Freeman, Springfield; J. T. Harrington, Youngstown; T. A. Kenney, New York; C. S. MacCalla, Youngstown; H. E. Miller, Springfield; J. G. Robertson, Akron; L. G. Tighe, Akron; W. L. Willkie, New York. Mr. Barthold, Mr. Kenney and Mr. Harrington are also vice-presidents, as is M. W. Arthur of New York.

Ohio Edison Company assumes all the bonds and other indebtedness of the Pennsylvania-Ohio Power & Light Company, Northern Ohio Power & Light Company, the Akron Steam Heating Company, the Ohio Edison Company and the London Light & Power Company.

"Selling Transportation" Is Theme of Coffin Award Review

While it is impractical, of course, to make the full text of the Charles A. Coffin Award briefs available for general circulation, the American Electric Railway Association has done much to overcome this deficiency by publishing a digest in which the outstanding features of the respective briefs are set forth. The latest publication of this nature, covering the briefs submitted in the 1928 and 1929 contests, is now being distributed from the association headquarters to member companies. The book is entitled "Selling Transportation." It has been prepared under the direction of Prof. Albert S. Richey, acting for the Coffin Foundation, with a foreword by J. P. Barnes, president of the association in 1928-29.

The street railway companies which competed for the award in 1928 were: El Paso Electric Company, Gary Railways, Northern Texas Traction Company, San Antonio Public Service Company, Shreveport Railways, and Virginia Electric & Power Company. The El Paso Electric Company and the Northern Texas Traction Company were again contestants in 1929, and in addition briefs were submitted by Chicago, South Shore & South Bend Railroad, Community Traction Company (Toledo), Detroit Department of Street Railways, Houston Electric Company, and the Youngstown Municipal Railway.

Conforming to its title, "Selling Transportation" is made the central theme of the book, and the various chapters, dealing with service betterment, selling rides, going after business, new and modernized cars, the place of the bus, rolling stock and track maintenance, safety, and employee co-operation, are all edited with emphasis upon this main idea of disposing of the product of transportation.

Under the general heading of service betterment, the matter of speed receives special attention. As one of the briefs expresses it, "speed is the very essence of transportation." The Gary Railways, realizing that railways must speed up to exist, points out how it has increased its average speed from 9.11 to 9.95 m.p.h. The Detroit Department of Street Railways features its rapid transit surface line, the Jefferson Avenue Express, which, in 1928, maintained an average schedule speed of 18.5 m.p.h. over its 4.3 mile route, while the Chicago, South Shore & South Bend Railroad credits its high speed interurban service with having done much to check automobile competition.

Perhaps more than ever before is recognition given to the human element and its responsibility in the sale of service. Practically every brief submitted placed special emphasis upon this feature, and the winning companies, the Virginia Electric & Power Company in 1928 and the Chicago, South Shore & South Bend Railroad in 1929, credit their exceptionally successful records largely to this factor. There is a growing appreciation of the fact that it is the man on the platform who makes the service either satisfactory or otherwise. The efforts of the personnel have been supplemented and backed up by the efforts of the companies in cleaning and painting, and in making the physical plant more attractive.

Advertising and newspaper publicity have attained a much higher level, according to the chapter devoted to this subject. Public relations have greatly improved and, thanks to a general policy of supplementing words with actions, there is, in general, a growing feeling of mutual confidence between electric railway managements and the public and local authorities. This is made evident by the success of Houston in securing relief from jitney competition; of San Antonio, where an increase in fares was granted; and Toledo and Youngstown where notable progress was reported in securing franchises free from many of the onerous impositions of the past.

The chapter on operating economies contains much information of a general nature on this subject, while the chapters on rolling stock maintenance, track construction and maintenance and power and line economies constitute a veritable handbook of good operating practice in these important fields. Solicitude for the general welfare, health, happiness and contentment of employees, individually and as a group was manifest in all presentations. That this has been reciprocated is made evident by the more intelligent co-operation between men and management which characterizes the general trend of employee relations.

In his foreword, Mr. Barnes has aptly expressed the aim and purpose of the volume. "It is offered," he states, "with the hope that the fundamental and far-reaching policies which have characterized award submission of the last two years will prove of maximum inspiration to a maximum number of readers."

Conspectus of Indexes for July, 1930

*The three index numbers marked with an asterisk are computed by Mr. Richey, as follows: Fares index is average street railway fare in all United States cities with a population of 50,000 or over except New York City, and weighted according to population. Street Railway Materials index is relative average price of materials (including fuel) used in street railway operation and maintenance, weighted according to average use of such materials. Wages index is relative average maximum hourly wage of motormen, conductors and operators on 136 of the largest street and interurban railways operated in the United States, weighted according to the number of such men employed on these roads.

Noise Elimination in Rapid Transit Studied

Under the direction of Robert Ridgway, chief engineer, the transit experts of the city of New York have been making a thorough study of proposals for the improvement of equipment, rolling stock, road ballast and subway turnstiles to eliminate all unnecessary noises. They also have under consideration the advisability of sound-deadening linings for the reduction of loud noises caused by fast operation of trains through underground tubes.

The city's engineers believe that the method of laying tracks on ties imbedded in concrete, now being used in the new subways, will be less productive of operating noises than the use of the stone or gravel ballast. The latter method, they believe, results in failure of track alignment, low rail joints and other noise-producing defects.

The engineers have designed the city's new subway cars so that they will operate with a minimum of noise. They are also studying the suggestion that subway tubes be sheathed, or partly sheathed, with some sound-deadening application or material, but thus far have come upon no practical method of accomplishing this result.

In a report to Chairman Delaney, Mr. Ridgway pointed out that the problem of eliminating noise from subway and elevated operation was studied as early as 1923 when a special committee was named. Since that time the Board of Transportation's engineers have studied surveys made by operators of the London Underground Railway in an effort to reduce operating noises.

FOREIGN NEWS NOTES

Construction of New London Subway Approved

The Select Committee of the British House of Lords has approved the preamble of the bill for the extension of the Piccadilly subway, London, from Finsbury Park to Cockfosters. The measure has already passed through the House of Commons Committee, so that, subject to the formality of the Royal assent, the London Underground Railways combine proposes to have the contract ready for inviting tenders for the work returnable by July 15. Actual work will be started not later than Sept. 1.

The London & North Eastern Railway was the principal opponent of the bill before the committees of Parliament. That company's decision to electrify its suburban lines was subject to two conditions, a satisfactory financial grant from the government under the Development Act, and a satisfactory arrangement for terminal accommodation in central London. The subway project has not killed the electrification proposals. Approval of that bill means competition by subway with that part of the Northeastern line it is proposed to electrify. Should the company not electrify its lines, the loss of traffic to the new subway will be much heavier. Final decision is not likely until the amount of state assistance the company will receive is known.

✦

London's New Suburban Line

The chief event of the New Year in London up to the present has been the opening of the electrified extension of the Southern Railway's suburban system, linking Wimbledon and Sutton, southwestern suburbs. During business hours trains from these terminals now run to central London every twenty minutes, and every half-hour at other times. The value of this extension will increase with the development of the St. Helier, Sutton Common, and Sutton West districts. From St. Helier station, which serves the new London County Council housing estate, central London is reached in 34 minutes. The new piece of line is 5¼ miles in length, and there are six new stations. Work on the section began in October, 1927, and 24 bridges had to be built, including three foot bridges. The trains are composed of eight coaches, giving room for 112 first-class and 540 third-class passengers. Cheap weekly, monthly, and quarterly season and cheap day-return tickets are available, and will help popularize the service.

In this connection it should be noted that the electrification of three important new sections of the Southern Railway, one of Britain's railroad "Big Four," is to be completed this year, under the construction plans for 1930. The total expenditure authorized for the year is $21,500,000, about one-third of which will go to pay for new rolling stock. Approximately $3,000,000 will be spent on electrification.

✦

Scenic Trips by Electric Railway in Japan

Electric railways operating from Osaka, Japan, to many suburbs, including Kyoto, Kobe, Wakayama and Nara, enable the tourist to visit many temples, shrines, tombs and scenic points. The Daiki Railway goes to Nara, the ancient capital of Japan, where are the Kasuga Shrine, the Todaiji Temple and the great Buddha. Nara is only a 50-minute ride from Osaka. The trip on the Keihan permits the visitor to see the mausoleum where the late Emperor is buried, and visit Lake Biwa and the cherry blossom region of Mount Arashiyama. Koshien Field with a grandstand and bleachers seating 80,000 persons, is reached on the Hanshin line. Not only have the Japanese gone in for utility as instanced by their rapid transit lines, but they have not neglected the aesthetic side as one of the two accompanying pictures makes plain.

Incidentally it should be noted that plans are being made for further electrification of the Japanese government railways. The portions under consideration are those between Tokyo and Yokosuka, Kozu and Atami, Ueno and Abiko, Yokohama and Hachioji, Tachikawa Asakawa, Kioto and Nara, Tennoji and Umeda, Otsu and Akashi. Details of the plans are being worked out by a special committee in the railway office. When electrification is completed, it is expected to have a considerable influence on the passenger traffic of the existing interurban lines. Overhead contact lines have already been installed on the section between Tokyo and Yokosuka and between Kozu and Atami.

✦

Subway Financing for Buenos Aires Arranged

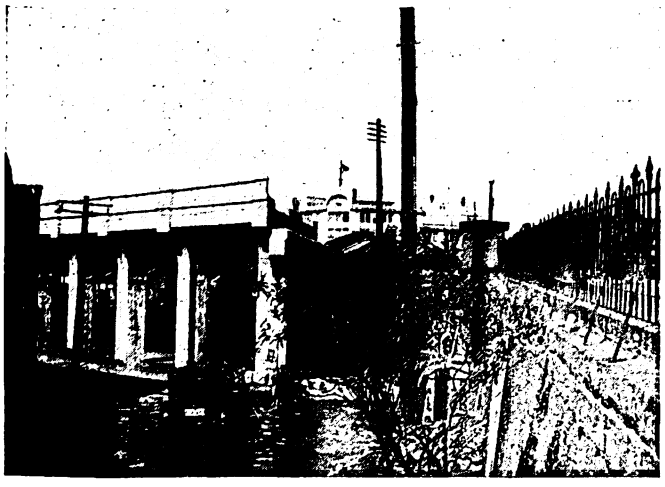
Harris, Forbes & Company, New York, have underwritten financing of a new terminal and subway project in Buenos Aires. Financing will be $12,000,000 three-year 6 per cent notes of South American Railways, which will be convertible into common stock with purchase warrants attached of the latter company. This financing, with proceeds of $2,500,000 preferred stock sold recently, will enable South American Railways to purchase $14,500,000 three-year notes of Buenos Aires Central Railroad & Terminal Company, which is constructing and will operate a subway and terminal project to give it and its interconnecting systems direct access to the heart of the business district of Buenos Aires.

✦

Rome, Italy.—Electrified lines of the Italian State Railways now number 1,625 kilometers, or about 10 per cent of the mileage of the entire state railway system. However, they carry 20 per cent of the total traffic. The use of electricity now permits the state railways to save about 600,000 metric tons of coal annually or slightly less than one-quarter of that which is burned for steam traction. During the past year, 100 locomotives were purchased by the state railway system. Of these 85 were electric.

✦

Mendoza, Argentina—The Mendoza Empresa de Luz y Fuerza, furnishing electric power, light and electric railway service to Mendoza, the fourth largest city in Argentina, has been acquired by the American & Foreign Power interests, which have concluded negotiations for the acquisition also of properties owned by the Compania de Electricidad de la Provincia de Buenos Aires in the cities of Mar del Plata, San Pedro, San Nicolas, Junin, Azul and San Luis. Mendoza, with a population of 175,000, is the metropolis of western Argentina.



A Difficult Piece of Diversion Work on the Elevated Electric Railway, Now Under Construction in Kobe, Japan

White Tile, Electric Direction Signs and Modern Lighting Fixtures Are Features of the Kobe-Arima Railway Station

PERSONAL MENTION

A. B. Paterson New President in New Orleans

A. B. Paterson, who has been vice-president and general manager of the New Orleans Public Service, Inc., New Orleans, La., has been elected president of the company to succeed Herbert B. Flowers, resigned. Mr. Paterson has already been named to the vacancy by the board of directors, and will assume his new duties immediately. No action has been taken as yet with regard to the position left vacant by Mr. Paterson's promotion.

The new president of Public Service, Inc., has been with the company for the past ten years, and is widely known in the public utility field. He entered the business in 1905 when he became connected with the Meridian Light & Railway Company, where he remained

A. B. Paterson

twelve years as vice-president and general manager.

He went to New Orleans in 1917 as representative of Henry L. Doherty & Company, operators of Cities Service Company of New York and other large utility concerns. Later he entered the employ of Isidore Newman & Sons, operating utility properties in New Orleans and other Southern cities.

In 1920, Mr. Paterson became associated with old New Orleans Railway & Light Company, predecessor of the New Orleans Public Service, Inc., as engineer in an advisory capacity, and soon after the reorganization of the company, under the name of New Orleans Public Service, Inc., was appointed general manager. Later he was elected a vice-president of the company, and last year was made a member of the board of directors.

✦

Carl H. Schildgen North Shore Industrial Agent

A new phase in an organized effort to locate new industries in the territory served by the Chicago North Shore & Milwaukee Railroad and associated lines has been entered by appointment of Carl H. Schildgen as industrial agent in charge of industrial development on the North Shore and the Chicago, Aurora & Elgin Railroad. Charles G. Finnegan has been named assistant industrial agent on both roads by Col. R. H. James, vice-president in charge of traffic.

Mr. Schildgen was formerly general freight agent of the North Shore Line and Mr. Finnegan has been actively identified with industrial development on the North Shore Line for some time.

Gorman Bennett has taken over Mr. Schildgen's former duties in addition to his own work in charge of less-than-carload freight business.

✦

Robert Ridgway to Assist in Chicago Subway Work

Robert Ridgway, chief engineer of the Board of Transportation of New York City, was appointed on July 14 chief consulting engineer of the Chicago subway. He will serve Chicago with the consent of the Board of Transportation.

Mr. Ridgway has been chief engineer of the Board of Transportation since its organization in 1924. When he became associated with the old Rapid Transit Construction Commission in 1900 in building the New York's first subway he had already achieved a record in railroad construction in the West and in building the New York City aqueduct for water supply.

His advice has frequently been sought on subway building in European and South American cities and he has made frequent trips abroad to study rapid transit. In 1927 he aided engineers in the location of the bridge across San Francisco Bay. He was also a member of the commission which picked the Boulder Dam power site. Last year he was a delegate to the World Engineering Congress in Tokyo.

✦

L. V. Johnston Master Mechanic at Peoria

Leonard V. Johnston, formerly in charge of maintenance of buses for the Peoria Division of the Illinois Power & Light Corporation, has been appointed master mechanic, succeeding A. T. Leech, deceased. Mr. Johnston went to Peoria in 1915 as maintenance man and engineer for several different power plants. In 1921 he went to work for the Illinois Traction System at the Peoria plant as maintenance man and engineer. Four years later he was promoted to the position of chief engineer. He was placed in charge of the maintenance of buses in 1929.

Mr. Johnston's career has been a varied one. In 1906 and 1907 he was in the employ of the Thomas Fee Construction Company, Chicago, building a dam across the St. Croix River at St. Croix Falls, Wis. From 1907 to 1910 he was in train service on the Northern Pacific between St. Paul and Duluth. After three years of this he worked as construction foreman for the Hydraulic Engineering Company on the building of the Keokuk dam at Keokuk, Iowa. Thence he went to Peoria.

C. D. Emmons President of the Hudson Tubes

Charles D. Emmons, formerly president of United Railways & Electric Company of Baltimore, has been elected president of Hudson & Manhattan Railroad, New York, effective on Sept. 1, succeeding Oren J. Root, resigned.

Mr. Emmons has had long experience in public utility and railroad work. Having graduated in 1892 from the University of Pittsburgh, with the degree of civil engineer, Mr. Emmons during the following nine years served in the engineering department of the Pennsylvania Railroad. From 1901 to 1903 he served as general superintendent of the Lafayette Street Railway, Lafayette, Ind., and from 1903 to 1911 was general manager of the Ft. Wayne & Wabash Valley Railway, Fort Wayne, Ind. In the succeeding four years he was with the Chicago, South Bend & Northern Indiana Railway.

In 1916 Mr. Emmons became vice-

C. D. Emmons

president and general manager of the Boston & Worcester Street Railway, and in 1918 general manager of the Boston Elevated Railway. From 1919 until his recent resignation he was president of the United Railways & Electric Company of Baltimore.

In 1922-23 Mr. Emmons was president of the American Electric Railway Association.

✦

K. D. Pulcipher in Charge of Pennsylvania Publicity

K. D. Pulcipher has been made manager of the publicity department of the Pennsylvania Railroad. He succeeds G. B. Harley, who has been appointed special assistant to the vice-presidents.

Mr. Pulcipher has been editor of the *Pennsylvania News*, Western region edition, the employee semi-monthly newspaper of the railroad. He was a staff writer for the Associated Press prior to his connection with the railroad.

Ray D. Casey, formerly special publicity representative of the Pennsylvania in Philadelphia, succeeds Mr. Pulcipher as editor of the *Pennsylvania News* in Chicago. G. E. Payne has been appointed assistant publicity manager in Philadelphia.

T. H. Tutwiler Withdraws from Active Business

T. H. Tutwiler, president of the Memphis Street Railway, Memphis, Tenn., for 25 years, and president of the Memphis Power & Light Company since its reorganization seven years ago, has resigned both of these posts as part of his plan to withdraw from all active participation in business as an executive.

Mr. Tutwiler's most outstanding contributions to the electrical industry were in the railway field, where he has been long recognized as an organizer and builder. A Southerner by birth—a Virginian—his first efforts were in that section of the country with the Georgia-Pacific Railway and the Louisville, New Orleans & Texas Railroad. From 1892 to 1901 he was engineer in charge of the larger part of the New Orleans Street Railway system. He then became associated with Ford, Bacon & Davis as engineer of the Birmingham Street Railway, and was also associated with Ford, Bacon & Davis as one of the engineers

T. H. Tutwiler

in charge of converting the railway system of the two Kansas Cities from cable to electric power. In 1903 and 1904 he had charge of the rehabilitation of the Nashville Street Railway system, being associated with Ford, Bacon & Davis in that work also.

In 1905, at the invitation of the Newman interests, Mr. Tutwiler removed to Memphis as vice-president and operating general manager of the Memphis Street Railway, of which he became president in 1906. It was through his efforts and ability that the system was placed on such a solid basis of operation that it conspicuously withstood the harassing conditions which afflicted practically all electric railway systems following the World War. He practically rebuilt the entire system of the Memphis company. On Jan. 1, 1923, at the termination of the receivership of the Memphis Gas & Electric Company, Mr. Tutwiler was made president of the reorganized company, known as Memphis Power & Light Company. He is a member of the American Society of Civil Engineers, Engineers Club of Memphis and Louisiana Engineering Association.

✦

E. L. Moore, who succeeds the late G. R. Millican as general superintendent of the Evansville & Ohio Valley Railway, Evansville, Ind., has been in the employ of the company for 22 years. In 1908 he went to Evansville from his home city of Columbus, Ind., where he was employed by the Interstate Lines. At Evansville he became trainmaster and later superintendent of transportation for the Evansville & Ohio Valley Railway.

✦

J. R. Snider Chief Operating Executive at Grays Harbor

J. R. Snider, veteran southwest Washington utility executive, is the new vice-president and general manager of the Grays Harbor Railway & Light Company. Mr. Snider, manager of the Willapa Electric Company, Raymond, Wash., for many years, will retain his position as head of the neighboring utility in addition to his responsibilities as general manager at Grays Harbor. He also will continue as active head of the Western Washington Electric Light & Power Company.

Mr. Snider has been connected with the electrical industry in western Washington since 1912 when Sanderson & Porter did development work on Willapa harbor. He became manager of the Willapa Electric Company in 1917, and has since continued in that capacity.

Mr. Snider is a native of Wisconsin. He was graduated from the law school of the University of Wisconsin, and was admitted to the bar in that state.

Mr. Snider succeeds the late W. W. Briggs as head of the electrical operations on Grays Harbor, directed, since the death of Mr. Briggs on Dec. 9, 1929, by the other officers and department heads.

✦

David E. Matthews South Shore Superintendent

David E. Matthews has been appointed general superintendent of the Chicago, South Shore & South Bend Railroad to succeed J. K. Gray, retired, effective Aug. 1.

Mr. Matthews goes to the South Shore Line with a background of more than 40 years of practical railroad experience. He was connected with the Pennsylvania Railroad for 21 years, starting as a brakeman and becoming successively freight conductor, passenger conductor, yardmaster, and assistant to the superintendent, doing special supervisory work. He has been railroad inspector and examiner for the Public Service Commission of Indiana since its creation, and with its predecessor, the old Railroad Commission since 1905.

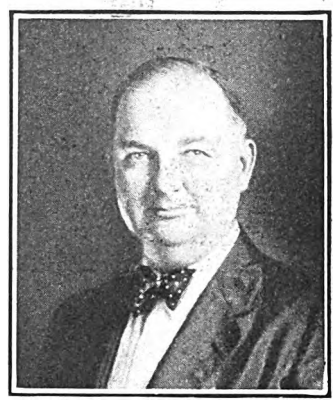
Mr. Matthews' whole career has been closely identified with railroad operation, including the investigation of accidents, handling of traffic and inspection of equipment. He has been active in the promotion of safety to passengers and employees on the Pennsylvania System and later in connection with his work for the Public Service Commission.

Mr. Gray, who is retiring, has served as general superintendent of the South Shore Line for the past thirteen years. Previously he was superintendent for six years, and assistant superintendent for one year.

W. D. Kyser Heads Memphis Utilities Including Railway

W. D. Kyser, a Memphis lawyer, has been elected president and general counsel of the Memphis Power & Light Company. His election followed the resignation of T. H. Tutwiler, president of the company since its reorganization seven years ago. Mr. Kyser also has been named president of the Memphis Street Railway, a subsidiary. He has been president of the West Tennessee Power & Light Company for nearly two years and vice-president and attorney for the Memphis Natural Gas Company. He will retain both offices. The West Tennessee Power Company is a member of the Electric Bond & Share group with the Memphis Power & Light and the Memphis Street Railway. Thus Mr. Kyser becomes the dominant figure in the principal public utilities at Memphis. He will retain his partnership in the law firm of Wilson, Kyser, Armstrong & Allen.

Mr. Kyser has practiced law in



W. D. Kyser

Memphis for more than twenty years. He was born in Richmond, Ala., on July 17, 1882, and received his early education there. He was graduated from the University of Alabama in 1903 with the degree of Bachelor of Arts. Later he earned an L.L.B. degree from Cumberland University.

Entering the practice of law in Memphis after leaving Cumberland, he became associated with the firm of Carroll & McKellar in Memphis, and, in 1909, formed a partnership with Mr. McKellar, now United States Senator.

Senator McKellar and Mayor Overton have retired from active membership in the law firm since entering politics. Judge Julian Wilson and Walter Armstrong only recently became partners with Mr. Kyser and Mr. Allen.

Mr. Kyser has made only one venture into politics—when he served as United States District Attorney for the western district of Tennessee from 1917 to 1921.

✦

L. Mackinnon, general manager of Glasgow Tramways, and F. A. Fitzpone, general manager of Edinburgh Tramways, have been elected president and vice-president respectively of the Scottish Tramways & Transport Association for the ensuing year.

H. B. Flowers Resigns from New Orleans Public Service, Inc.

Herbert B. Flowers, president of New Orleans Public Service, Inc., New Orleans, La., since 1923, has resigned as chief executive of the company, to engage in business in New York in the fall.

Mr. Flowers has been connected with utility concerns for the past 30 years. He assumed the presidency of Public Service in April, 1923, soon after the reorganization of the New Orleans Railway & Light Company, succeeding Mr. Hecht, who had been acting as president pending the selection of a head for the enterprise.

He went to New Orleans from Baltimore, where he was then vice-president and general manager of the United Railway & Electric Company. Prior to his

H. B. Flowers

Baltimore connections, Mr. Flowers had spent seven years with the electrical and transportation departments of the Detroit United Railway.

As head of New Orleans' largest enterprise, Mr. Flowers has been prominently identified with the civic and commercial life of the city, taking an active part in the work of the community chest, the Boy Scouts, and other organizations. He is also chairman of the industrial bureau of the Association of Commerce, and has actively assisted in the work of the national advertising committee of the association, having been in charge of the temporary offices opened by the organization in Chicago and in New York to establish contact with Northern industrial leaders.

✦

Messrs. Woodworth and Smith in New Vanadium Posts

C. B. Woodworth, who has been manager of the western division of Vanadium Corporation of America at Chicago, has been appointed manager of the railroad division of the corporation. His headquarters will continue in Chicago.

Walter Smith has been appointed assistant manager of the railroad division of Vanadium Corporation. He will also make his headquarters in Chicago.

Mr. Smith was graduated in mechanical engineering, Cornell University, 1909. He entered railway service with the Chicago, Rock Island & Pacific, and subsequently served the Baltimore & Ohio and the Chicago & Northwestern in various supervisory capacities.

In 1916 Mr. Smith entered the service of Pyle-National Company, Chicago, leaving this company for service in the American Expeditionary Force. After the armistice, he was associated with the Inter-Allied Railroad Commission and supervised the transfer of cars and locomotives in Germany in accordance with reparations agreements.

Upon his return to this country, Mr. Smith resumed his service with the Pyle-National Company, with which he was engaged as special representative on sales and service work until his association with Vanadium Corporation of America.

✦

Brooklyn Man to Instruct Buenos Aires Operators

Theodore Francis Kramer, instructor of motormen for the Brooklyn-Manhattan Transit Corporation, Brooklyn, N. Y., has left for South America to take charge of the Buenos Aires Central Railroad Company's operating force. Just previous to his departure his associates presented him with a handsome traveling bag, with all the necessary toilet requisites, a fitting reminder of their good wishes for his welfare. The Buenos Aires Central Railway is getting ready to operate its newly built subway in Buenos Aires, and asked one of the engineers of Dwight P. Robinson & Company to designate a man from the Brooklyn company who could take charge of their operative force, and give them the necessary instruction on the Westinghouse Air Brake System. Mr. Kramer was the one decided upon. He was approached and accepted the post, the Brooklyn company giving him the needed leave of absence during the temporary assignment to the system at Buenos Aires.

✦

Giuseppe Faccioli Retires From Active Service

Giuseppe Faccioli, widely known electrical engineer, has relinquished his duties as Pittsfield works engineer and associate manager of the Pittsfield works of the General Electric Company and assumed the position of consulting engineer.

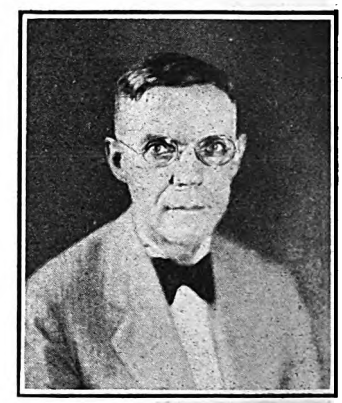
Born in Milan, Italy, Giuseppe Faccioli came to this country more than 25 years ago. He was employed by the New York Edison Company and later by the Interborough Rapid Transit Company. He then became a designing engineer for the Crocker-Wheeler Company. It was during the latter period that he met William Stanley, then wrestling with his new alternating current generator. Mr. Faccioli figured to the precise amperage which a given machine would deliver, whereas anywhere within 10 per cent would have been considered remarkable.

Soon after that he came associated with Mr. Stanley at the latter's home in Great Barrington. In 1908 he became identified with the Pittsfield works of the General Electric Company where his mathematical genius proved unusually valuable in all problems pertaining to the products of that plant, mainly transformers. Mr. Faccioli also spent considerable time at Schenectady where he was associated with the late Dr. Charles P. Steinmetz.

H. W. Smith Succeeds Late A. E. Harvey at Kansas City

Howard W. Smith, connected with the engineering and way and structures department of the Kansas City Public Service Company, Kansas City, Mo., since 1911, has been appointed to the office of superintendent of way and structures with that company, to fill the vacancy caused by the death of A. E. Harvey.

Before his entry into the street railway business, Mr. Smith was widely known on the steam roads of the Northwest. He pioneered in the survey for the Puget Sound division of the Chicago, Milwaukee & St. Paul road. He went to the Kansas City property as an assistant engineer, and served in that capacity until the organization of the



H. W. Smith

Kansas City Railways under the direction of Philip J. Kealy when he was made assistant superintendent of way and structures, directly under Mr. Harvey.

In 1926, when the Public Service Company took over the property and a city-wide program of reconstruction was started under the direction of a construction department organized for the purpose, Mr. Smith was appointed superintendent of way and structures. The construction department was placed under the direction of Mr. Harvey.

When the reconstruction work was complete in 1928, the construction department was disbanded and Mr. Harvey was again returned to the head of the way and structures department with Mr. Smith as his assistant.

Mr. Smith was born in Grand Rapids, Mich., in 1883. There he lived until 1903 when he went to Kansas City. From 1902 until 1906 Mr. Smith was actively engaged in road survey work in Missouri and in Michigan. From 1906 to 1909 he was resident engineer in the construction of the Pacific Coast extension of the Chicago, Milwaukee & St. Paul Railroad.

✦

W. C. Ludwig, superintendent of transportation for the United Railways & Electric Company, Baltimore, recently completed 50 years of service with the Baltimore system and was tendered a dinner by the line superintendents of the company. He became connected with the system as a hill-boy for the City Passenger Railway.

Chairman of Toledo Control Board Resigns

W. W. Knight, a member of the board of street railway control at Toledo, Ohio, for nearly ten years, and recently the chairman of the board, has submitted his resignation to Mayor W. T. Jackson due to his change of residence. Mr. Knight helped to draft the Milner ordinance, under which the Community Traction Company operates, and has continued to serve as one of the three members of the board ever since.

✦

Frank E. Belleville Made Secretary at Louisville

Frank E. Belleville has been elected secretary of the Louisville Railway, Louisville, Ky., to fill the vacancy created by the resignation of Samuel Riddle. Mr. Belleville will retain his position as general auditor in addition to acting as secretary.

Mr. Belleville was born in Rutland, Vt., on Dec. 18, 1883. He was connected with the Rutland Railway, Light & Power Company from 1901 to 1907, at which time he went with the United Traction Company, Albany, N. Y. He remained with this company until

F. E. Belleville

March, 1909, when he became auditor of the Schenectady Railway, Schenectady, N. Y. In 1920 he went to Louisville as general auditor of the Louisville Railway and subsidiaries.

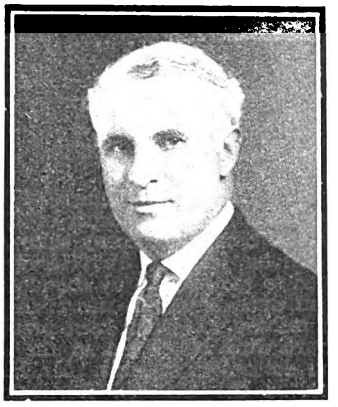
✦

J. G. Naughton in New Office With Indiana Interurban

John G. Naughton has been appointed general freight and passenger agent of the Terre Haute, Indianapolis & Eastern Traction Company, Indianapolis, Ind., to succeed John H. Crall, resigned.

Mr. Naughton started his railway career as secretary to the superintendent of the Lake Erie & Western Railroad at Lafayette, Ind., in 1908. He entered the employ of the T. H. I. & E. several years later as chief clerk of the traffic department. In 1929, he was made assistant general freight and passenger agent and succeeded Mr. Crall on June 1 of this year.

Mr. Naughton is a member of the storage and demurrage committee of the Central Electric Traffic Association and of the Traffic Club of Indianapolis.



R. E. Cosgrove

"Bob" Cosgrove Relinquishes Post at Springfield

Robert E. Cosgrove has resigned as superintendent of the traffic department of the Springfield Street Railway, Springfield, Mass., effective July 31. Oversight of traffic will be vested in H. M. Flanders, general manager.

"Bob" Cosgrove is known far and wide in the Springfield-Worcester district, largely because of his connection with the railways there, which began in 1906. At one time seventeen companies in the railway field were affiliated with the group with which he was identified. In his post of freight and passenger agent in charge of passenger traffic, freight traffic, tariffs, rates and other similar matters, he was for many years the contact man of the company. He has acted in the same capacity up to the present time and has made up all tariff rates and schedules of all companies with reference to fares and fare collections, and he had direct charge of trolley freight until that service was abandoned a few years ago. Mr. Cosgrove also devised and placed in operation the present system of transfers and tickets in Springfield and Worcester.

"Bob" Cosgrove was born in Winchester, Mass., Sept. 24, 1885. He was graduated from Winchester High School and Burdette College, Boston. He held a position as stenographer with the Corporation Trust Company, Boston, and entered the employ of the New England Investment & Securities Company, controlling the Springfield, Worcester and other electric railways, on Dec. 13, 1906, as stenographer and order clerk in the office of J. F. McCabe, purchasing agent.

When the Legislature of Massachusetts passed a law which forced the New Haven Railroad to divest itself of all of the electric railways in Massachusetts, the offices then in the South Station Building, Boston, were moved to Springfield. This occurred Sept. 24, 1908.

At the time of the removal to Springfield, "Bob" acted as stenographer to C. V. Wood, general traffic manager. When Mr. Wood was made vice-president of the companies, Mr. Cosgrove was appointed freight and passenger agent, in charge of passenger traffic, freight traffic, tariffs, rates, etc.

R. L. Hermann Heavy Traction Representative

R. L. Hermann, formerly transportation manager of the Southwestern district of the Westinghouse Electric & Manufacturing Company, has recently been appointed heavy traction representative, with headquarters in New York. With the exception of three years of service in the army, he has been identified with the Westinghouse Company continuously since his graduation from the University of Illinois in 1915.

✦

C. J. Roggi on Journal Staff

Charles J. Roggi has joined the staff of Electric Railway Journal as assistant editor. Mr. Roggi, a recent Massachusetts Institute of Technology graduate, directed his entire collegiate training toward the field of transportation.

His work at M.I.T. began in 1925 with his enrollment in the five-year co-operative course in electrical engineering during which he obtained about 68 weeks of co-operative practice with the Boston Elevated Railway. This practice was in the nature of a student apprentice course in which he spent some time in practically every department of the company.

C. J. Roggi

Not content with that, he attended the Harvard School of Business Administration during his last year at "Tech." There, as a special student, he took courses in traffic management and public utility management. He was graduated from M.I.T. this year with B.S. and M.S. degrees. Mr. Roggi was born in Brooklyn, N. Y., in 1907.

✦

Major James A. Fagan Retires

Major James A. Fagan, for 31 years an engineer with the Ohio Valley Electric Railway, Huntington, W. Va., and for many years chief engineer and engineer of maintenance of way of the company, has resigned. Major Fagan is now on a vacation in the West. He went to Huntington when the railway, then in its infancy, was owned by the late Senator J. M. Camden and his associates. In his early days with the company he supervised the building of the carhouses at Huntington and at Ashland and Kenova and has since taken an active part in practically all improvements carried out by the company.

Digitized by Google

Thomas Nicholl Will Succeed Mr. Scullin With Cleveland Road

Terance Scullin, veteran superintendent of buildings and equipment of the Cleveland Railway, Cleveland, Ohio, retired on pension July 31 under the company's retirement and benefit plan. Mr. Scullin has been in the employ of the railway for 42 years. He started under the late John J. Stanley when the latter was his father's assistant on the old Broadway & Newburgh Railway.

Mr. Scullin had been superintendent of buildings and equipment since 1909 and is responsible for many of the mechanical advances made by the company, including the development of the Peter Witt type of car.

Dr. George D. Upson, chief of the medical division of the accident department, will retire at the same time. He has been in the employ of the company for more than twenty years.

Mr. Scullin will be succeeded by Thomas Nicholl, who joined the research department of the company in 1929. Mr. Nicholl received his engineering education at the University of Michigan and until 1917 was superintendent of a utility property in Indiana operating in the power and railway fields. During the World War he was an infantry captain and later was superintendent of equipment of the Union Traction Company of Anderson, Ind. He is chairman of the committee on equipment of the American Electric Railway Association. He was also the first president of the Central Electric Railway Equipment Association, and is now chairman of that association's standardization committee.

Dr. J. G. Jones, who has been in the medical division of the Cleveland Railway since 1922, will succeed Dr. Upson.

Another Cleveland Railway promotion announced by President Alexander is the appointment of J. W. Kellison as assistant superintendent of buildings effective Aug. 1. Mr. Kellison was the first man employed by Colonel Alexander when the latter built the power plant for Tom L. Johnson's 3-cent fare line. He has been with Colonel Alexander ever since, serving in the executive department from 1920 to the present time.

✦

C. T. Long Succeeds J. A. Fagan at Wheeling

C. T. Long, engineer of the Public Service Company, Portsmouth, Ohio, has been appointed chief engineer of the southern division of the Ohio Valley Electric Railway. He will succeed Maj. James A. Fagan, who recently resigned. The division over which he will have supervision includes Huntington, Ashland, Portsmouth, Ironton and Wildwood, N. J.

Other changes in the personnel of the organization included the appointment of Carl J. Phipps, general superintendent to succeed Mr. Long as manager of the Portsmouth Public Service Company, a subsidiary.

Arch J. Riggell has been made assistant to the general manager in charge of transportation and Ham Adams, formerly in charge of personnel, will become sales manager.

OBITUARY

A. E. Harvey

Alfred E. Harvey, superintendent of the way and structures department of Kansas City Public Service Company since April, 1911, died on July 3. Mr. Harvey was appointed to the position by the late John M. Egan when Mr. Egan was at the head of the railway. He had been previously associated with Mr. Egan in the steam railroad work as an engineer. Mr. Harvey also served the Chicago, Burlington & Quincy, the Chicago Great Western and the Kansas City Southern roads.

When the present operators of the Kansas City railway took over the property following the reorganization there, a special department known as the construction department was established to

A. E. Harvey

take charge of a city-wide reconstruction program. Mr. Harvey was placed in charge of the new department. The Mill Street viaduct on the Dodson line—one of the city's most ornamental bridges—was also constructed under Mr. Harvey's supervision.

Mr. Harvey was the pioneer of present day track construction. Many of his experiments with steel and concrete in track work were nationally observed. He also developed many of the labor saving machines now in use on track work and paving projects. His first experiments were made on the Main Street track in 1912—the first concrete track laid in Kansas City. At that time the steel tie had not been fully developed and part of the Main Street work was poured over standard oak ties. Individual steel ties were, however, used in that portion of the Main Street track adjacent to the Union Station and on the viaducts and its approaches near the Station.

Another of Mr. Harvey's early experiments with concrete track construction was along Prospect Avenue from 39th to 48th Street. There track is constructed for half of its length over wood ties and for the rest of the distance over what is known as the twin steel tie. The surfacing of this track also introduced an innovation in construction work. This job was topped with crushed granite made from old paving blocks. For the crushing of these blocks Mr. Harvey designed a special crusher. Many of the practices of bonding the rails in city street track construction now in use were the outcome of experiments made by Mr. Harvey in Kansas City.

Mr. Harvey was also the author of many articles on track construction, and was a frequent contributor to ELECTRIC RAILWAY JOURNAL.

Mr. Harvey was born at Waverly, Ill., in 1868. He was a graduate of the civil engineering school of the University of Illinois, class of 1894. In 1893 Mr. Harvey served as assistant engineer in charge of water supply and sewers at the Columbian Exposition in Chicago.

At the time of his death Mr. Harvey was president of the Kansas City chapter of the American Society of Civil Engineers and a member of the standing committee on way and structures of the American Electric Railway Association. He was a past president of the Engineers Club of Kansas City.

✦

B. O. Brill

Byron O. Brill, general purchasing agent of the J. G. Brill Company, died suddenly in the Presbyterian Hospital, Philadelphia, on July 21, after a short illness.

Byron Brill joined the Brill company in 1898, and with the exception of six years from 1900 to 1906, when he was with the General Electric Company, at Schenectady, he has been connected with the Brill company. After having charge of lumber purchases, which department he joined in 1908, he was made general purchasing agent in May, 1922.

Mr. Brill was born on Aug. 23, 1879, at Williamsport, Pa. He was educated in the public schools of Williamsport and Philadelphia, and was graduated from the Spring Garden Institute of Philadelphia. His father, George Brill, was one of four sons of J. G. Brill, the founder of the company bearing his name.

Mr. Brill was a charter member of the Purchasing Agents' Association of Philadelphia, a member of the Academy of Fine Arts, Manufacturers Club, C. M. Swain Lodge 654 F. & A. M., Philadelphia Consistory A.A.S.R., and Lulu Temple A.A.O.N.M.S.

✦

C. W. Dickerson

Clarence W. Dickerson, vice-president and secretary of the Timken-Detroit Axle Company, died on July 1 at his home in Detroit. Mr. Dickerson was born on Dec. 28, 1859, at Brooklyn, N. Y. He was educated in the public schools of Springfield, Mass., and Brattleboro, Vt. He went to Detroit in 1910 as assistant treasurer of the Timken-Detroit Axle Company. His other business affiliations at the time of his death were vice-president and a director of the Michigan Mutual Liability Company, and a director of the Michigan Industrial Bank. For twenty years previous to going to Detroit, Mr. Dickerson was associated in executive capacities with Eastern bicycle companies.

✦

William H. McCurdy, 77 years old, one of the organizers of the Evansville & Ohio Valley Railway, Evansville, Ind., and a director in the company, died recently at San Diego, Cal.

INDUSTRY MARKET AND TRADE NEWS

Brooklyn Inaugurates Trolley Bus Service

On Wednesday, July 23, the Brooklyn & Queens Transit Corporation placed in service on the Cortelyou Road line the first trolley bus to be operated in Brooklyn. Operation is between Flatbush Avenue and Coney Island Avenue over a former electric railway route, and is in conjunction with a gasoline bus so that passengers can compare the merits of the two vehicles.

The trolley bus, which is supplied by the Twin Coach Corporation, is provided with leather-upholstered seats of the bucket type, with a seating capacity of 40 passengers. It is equipped with 50-hp. motors and has automatic control. A front entrance door is provided, with treadle-operated rear exit.

Operation on the Cortelyou Road line is of an experimental nature to enable patrons as well as the operating staff of the trolley company to make a practical test of this form of conveyance under actual operating conditions. Pamphlets describing the desirable features of the new vehicle are being distributed to passengers, and suggestions and criticisms are invited from the public.

Additions to Bates Expanded Steel Corporation

The Bates Expanded Steel Corporation, recently organized, has taken over the business of the Bates Expanded Steel Truss Company. The management is making changes in policies designed to greatly strengthen the corporation's position in its field. New designs of parallel expanded poles have been produced, and the company is actively developing a division for the manufacture of high-voltage transmission structural towers.

Judson F. Stone, of Chicago, is president of the new corporation, and Albert J. Bates, Jr., is vice-president and general manager. Mr. Bates has been closely identified with all activities of the company since 1917.

The corporation's facilities include a designing and engineering department, a large expanding and structural plant, and a galvanizing plant. Recent orders received include a large galvanized structural tower order from the Byllesby Engineering & Management Corporation for the Louisville Gas & Electric Company.

General Electric Sales at High Volume

General Electric Company sales billed for the first six months of 1930, announced by President Gerard Swope, amounted to $197,229,346, compared with $194,353,308 for the corresponding period last year. Profit available for dividends on common stock for the first six months of 1930 was $29,273,276, compared with $30,740,768 for the similar six months last year, or equivalent to $1.01 per share on outstanding common stock this year and $1.07 per share for the first half of 1929.

Valspar Expands

The Valspar Corporation has merged the Detroit Graphite Company of Detroit, Mich., and the Dominion Paint Works, Ltd., of Walkerville, Ont., with its already existing units. These two companies are wholly complementary to the other companies in the Valspar Corporation, both in the lines which they manufacture and in the location of their plants. The plans for consolidating the activities of the Detroit Graphite Company and the Dominion Paint Works with those of the other units of the Valspar Corporation do not contemplate any change in management or loss of identity in these two new subsidiaries.

The headquarters of the Detroit Graphite Company will remain in Detroit. Certain of its officers will be elected directors of the Valspar Corporation.

The Valspar Corporation now includes: Valentine & Company; Detroit Graphite Company; Cie. des Vernis Valentine; Con-Ferro Paint & Varnish Company; Dominion Paint Works, Limited; together with several subsidiary companies located both within the United States and abroad. The corporation also has plants in England and Australia.

Active Demand for Buses Among the Electric Railways

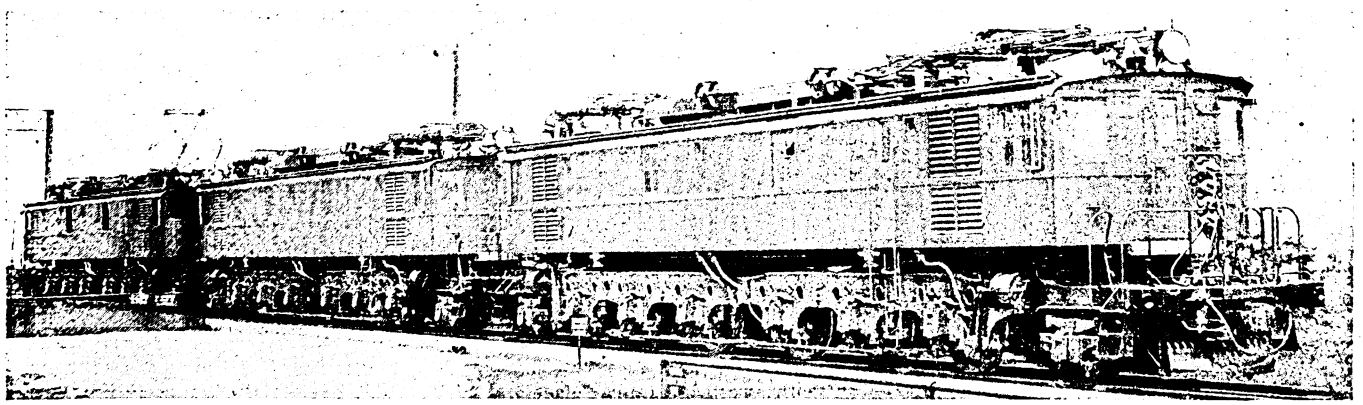
One hundred and sixty additional Type "250" Yellow buses, for which orders were placed some months ago, have been delivered to Public Service Co-ordinated Transport, Newark, N. J. The same company also received five Mack Model AB, 25-passenger buses, and three Mack Model AB, 29-passenger buses, all for city service and all equipped with gas-electric drive.

General Motors Truck Company also reports delivery of fifteen Type Z-225 buses to the Fifth Avenue Coach Company, of New York City, and ten Type "250," 33-passenger observation coaches to the Philadelphia Rapid Transit Company. Other General Motors Truck deliveries include five Type W, 21-passenger buses for city service to the Waverly, Sayre & Athens Traction Company, Waverly, N. Y.; five Type Z, 38-passenger city service buses to People's Motor Bus Company, St. Louis, Mo.; one of similar type to the Boston Elevated Railway; four Type W, 21-passenger buses, and six Type Z, 29-passenger coaches to Coast Cities Railway, Asbury Park, N. J.; and a Type W, 21-passenger coach and a Type Y, 29-passenger parlor bus to Union Street Railway, New Bedford, Mass.

Twin Coach deliveries include ten urban type buses to Schenectady Railway Company, six of similar type to Brooklyn Bus Corporation, and one to Boston Elevated Railway. Seven trolley buses were delivered to Chicago Surface Lines, and a parlor reclining bus went to the Washington Motor Coach Company, of Seattle.

Brooklyn Bus Corporation also took delivery of one Mack Model AB, 29-passenger bus and one Mack Model AC, 29-passenger bus, both of the city service type, and four Mack Model BK, 38-passenger city service buses. Mack International Motor Truck Corporation made delivery of five Model BG chassis

Electric Locomotives for Great Northern Railroad



Three 260-ton motor-generator type single-phase electric locomotives shown above are being tested for regenerative electric braking on the test tracks of the General Electric Company at Erie, Pa., before shipment to the Great Northern Railway. Four of these locomotives, practically duplicates of the four General Electric units that are now in operation on the Cascade Tunnel electrification in the state of Washington, are being shipped to the railroad.

Digitized by Google

to the Fishkill Electric Railway, Beacon.

American Car & Foundry Motors Company delivered five 40-passenger units to Boston Elevated Railway, six 23-passenger street car type coaches to the Aurora, Elgin & Fox River Railway, Aurora, Ill., and four 21-passenger parlor type coaches to the Fort Dodge, Des Moines & Southern Transportation Company, Boone, Iowa. Illinois Power & Light Corporation received three 33-passenger street car type coaches.

Boston, Worcester & New York Street Railway, Framingham, Mass., has accepted a White Model 54A bus and four White Model 54 buses. Other White deliveries include six Model 54 buses to West Penn Electric Company; one 54A bus to Washington Motor Coach Company, of Seattle; one Model 54 bus to United Electric Railways, of Providence, and one of similar type to the Los Angeles Railway.

G. E. Employees Favor Unemployment Insurance

More than 75 per cent of the eligible employees of the General Electric Company have voted to participate in the new General Electric Employees unemployment plan. In proposing this plan, under which the money will be raised by equal contributions from the employees and the company, it was stated that the plan would become effective upon an affirmative vote of 60 per cent of those eligible at each works.

Westinghouse Equipments for Detroit

The Westinghouse Electric & Manufacturing Company has received an order from the St. Louis Car Company for 65 car equipments to be placed in service in Detroit in the early fall. Forty-five of these are duplicates of similar equipment now operating in Detroit and twenty will be equipped with the Timken Model 52 truck.

Electrical Manufacturers to Exchange Technical Information

The English Electric Company announces that it has entered into an arrangement with the Westinghouse International Company and the Westinghouse Electric & Manufacturing Company whereby there will be an exchange of technical information on steam turbines and electrical apparatus. The arrangement includes the granting of licenses for the use of patents for the manufacture and sale of various products.

This arrangement gives the English Electric Company the benefit of the results of the extensive research work carried on by the Westinghouse Electric & Manufacturing Company. The technical and manufacturing link does not carry with it any control from America.

Ohmer Business Is Good

Some of the more important business received by Ohmer Fare Register Company, Dayton, Ohio, include: Sales of 146 fare registers to the Des Moines Railway and 105 fare registers to an Eastern transportation company.

New long term rental contracts have been closed with the Alabama Power Company for 37 fare registers; with the Northern Indiana Railway for 29 ticket-printing registers; with the East Penn Traction Company for 26 fare registers; with Atlantic City & Shore Railroad for 20 fare registers; with Lehigh Valley Transportation Company for 24 ticket-printing registers.

Yellow Truck Reports Good Half Year

Report of Yellow Truck & Coach Manufacturing Company, for the six months ended June 30, 1930, shows consolidated net profit of $1,437,863 after expenses and depreciation.

Consolidated income account for six months ending June 30, 1930, shows net sales of $26,963,994 as compared with net sales of $28,671,459 and $24,893,447 for the corresponding periods of 1929 and 1928, respectively. Net sales for the quarter ending June 30, 1930, were $16,233,998 as compared with $15,749,460 for the same quarter of 1929.

Paul W. Seiler, president, says: "The marked improvement in earnings during the second quarter over the first quarter reflects in large measure the influence of orders received during the first quarter. Production on these orders was well under way by the end of the first quarter, but actual deliveries were not made until the second period."

Bulletin on Electric Railway and Motor Coach Lighting

A new lighting bulletin, E-109 "Lighting Practice for Electric Railways and Motor Coaches" issued by the Westinghouse Lamp Company, contains Sections E 121-29, E 122-28, and E 123-29 of the A.E.R.E.A. Engineering Manual, reprinted by permission of the American Electric Railway Engineering Association.

Recommendations for motor coach and railway car lighting are presented in two sections, each dealing with general principles; lamps for interior and exterior lighting; fixtures and reflectors for interior lighting; head lights; accessory lighting; signal lights; illuminated signs; lighting loads; lighting plans; and wiring diagrams.

A third section contains recommendations for shop, office, and yard lighting with divisions on lamps; reflecting accessories; lighting intensities; foot candle intensities; shop lighting; car inspection pits; office lighting; yard lighting; distributed lighting; and floodlighting.

All recommendations embodied in this bulletin were compiled by A.E.R.E.A Rolling Stock Committee No. 4—Lighting, of which R. W. Cost, Westinghouse Lamp Company is chairman.

New General Electric Catalog

General Electric catalog GEA-600A, superseding all previous catalogs issued by the company, with the exception of those dealing with railway, mine and industrial supplies and merchandise products, has been issued. The book contains 1,146 pages, 8x10½ in., and is profusely illustrated.

The catalog is thumb-indexed in sixteen sections as follows: Generation, wire and cable, distribution transformers, arresters and capacitors, voltage regulators, switching equipment, switchgear, meters and instruments, lighting equipment, motors, motor applications, industrial control, transportation, industrial heating, miscellaneous, and indexes. In the indexes, products are classified both by subjects and by catalog numbers.

Electric Railway Material Prices—August, 1930

Metals—New York

Copper, electrolytic, delivered, cents per lb.	11.00
Lead, cents per lb.	5.25
Nickel, cents per lb., ingot	35.00
Zinc, cents per lb.	5.10
Tin, Straits, cents per lb.	30.125
Aluminum, 98 to 99 per cent, cents per lb.	23.30
Babbitt metal, warehouse, cents per lb.:	
Commercial grade	36.00
General service	31.00

Bituminous Coal

Smokeless mine run, f.o.b. vessel, Hampton Roads, gross tons	$4.15
Somerset mine run, f.o.b. mines, net ton	1.75
Pittsburgh mine run, Pittsburgh, net ton	1.45
Franklin, Ill., screenings, f.o.b. mines	1.70
Central, Ill., screenings, f.o.b. mines	1.15
Kansas screenings, Kansas City	1.85

Track Materials—Pittsburgh

Standard steel rails, gross ton	$43.00
Railroad spikes, drive ½ in. and larger, cents per lb.	2.80
Tie plates (flat type), cents per lb.	2.075
Angles bars, cents per lb.	2.75
Rail bolts and nuts, cents per lb.	3.90
Steel bars, cents per lb.	1.70
Ties, white oak, Chicago, 6 in. x 8 in. x 8 ft.	$1.40

Hardware—Pittsburgh

Wire nails, base per keg	$2.15
Sheet iron (24 gage), cents per lb.	2.50
Sheet iron, galvanized (24 gage), cents per lb.	3.20
Galvanized barbed wire, cents per lb.	2.85
Galvanized wire, ordinary, cents per lb.	2.80

Waste—New York

Waste, wool, cents per lb.	10.00 to 15.00
Waste, cotton (100 lb. bale), cents per lb.:	
White	9.00 to 12.00
Colored	6.00 to 10.00

Paints, Putty and Glass—New York

Linseed oil (5 bbl. lots), cents per lb.	14.4
White lead in oil (100 lb. keg), cents per lb.	13.75
Turpentine (bbl. lots), per gal.	0.47
Putty, 100 lb. tins, cents per lb.	5.725

Wire—New York

Copper wire, cents per lb.	12.75
Rubber-covered wire, No. 14, per 1,000 ft.	$5.05
Weatherproof wire base, cents per lb.	14.00

Paving Materials

Paving stone, granite, 5 in., f.o.b.: New York—Grade 1, per thousand	$150.00
Wood block paving 3½, 16 lb. treatment, N. Y., per sq.yd., f.o.b.	2.50
Paving brick 3½x8½x4, N. Y., per 1,000 in carload lots, f.o.b.	50.00
Paving brick 3x8½x4, N. Y., per 1,000 in carload lots, f.o.b.	45.00
Crushed stone, ¾-in., carload lots, N. Y., per cu.yd., delivered	3.40
Cement, Chicago, in carload lots, without bags, f.o.b.	1.95
Gravel, ¾-in., cu.yd., delivered New York	3.40
Sand, cu.yd., delivered New York	2.15

Old Metals—New York and Chicago

Heavy copper, cents per lb.	8.75
Light copper, cents per lb.	7.75
Heavy yellow brass, cents per lb.	5.25
Zinc, old scrap, cents per lb.	2.25
Lead, cents per lb. (heavy)	4.00
Steel car axles, Chicago, net ton	$15.25
Cast iron car wheels, Chicago, gross ton	13.75
Rails (short), Chicago, gross ton	14.00
Rails (relaying), Chicago, gross ton (65 lb. and heavier)	28.50
Machine turnings, Chicago, gross ton	6.25

Electric Railway Journal

Consolidation of
Street Railway Journal and Electric Railway Review
A McGraw-Hill Publication—Established 1884

JOHN A. MILLER, JR., *Editor*

Volume 74 New York, September, 1930 *Number 10*

Electric Railways Doing Well Compared to Other Industries

FOR the first six months of the present year, electric railway traffic was approximately 5 per cent below the corresponding period of last year. Compared with other industries this is a distinctly favorable showing. Statistics for the first half of this year show decreases ranging from 5 to 50 per cent in various lines of business. Among the significant decreases are the following: Department store sales, 5 per cent; coal production, 10 per cent; general manufacturing, 12 per cent; steam railroad earnings, 12½ per cent; textile manufacturing, 15 per cent; metal mining operations, 20 per cent; construction of all kinds, 27 per cent; automobile manufacturing, 31 per cent; metal working industries, 45 per cent; aircraft production, 50 per cent. On the other hand, small increases are shown in total use of electrical energy and in the food industries.

Business statistics for July show a continuation of the general downward trend of the first six months. Electric railway traffic was approximately 10 per cent below that of July a year ago. department stores sales were 9 per cent below, and general manufacturing nearly 20 per cent below. Since the beginning of August, however, there are some indications of improvement in the general business situation. Increased activity is evident in certain industries, with correspondingly increased employment. Recent reports received from a number of electric railways give reason to hope that August traffic figures may make a more favorable showing than did the July figures.

If the improvement which may reasonably be expected occurs during the four remaining months of this year, the electric railways will have suffered a less serious setback than many other industries. This is in line with experience during the business depression of 1921, as pointed out in an editorial in the November, 1929, issue of the JOURNAL, when it was predicted that a decrease in traffic of about 4 or 5 per cent might be expected during 1930. The fact that conditions in this industry were not so favorable a year ago as they were in many manufacturing industries partly explains the reason that the railways have not been more seriously affected. Nevertheless, it is evident that the basic reason for the railways' comparatively good showing is that transportation is an essential service and will be largely used, regardless of general business conditions.

Beware of Costly Economies

WITH electric railway earnings at a point considerably below normal, strenuous efforts are being made to reduce operating expenses. This is a perfectly natural reaction to the existing situation. Strict economy is necessary and undoubtedly will produce beneficial results, if not carried to excess. It must be remembered, however, that not every dollar cut out of operating expenses is a dollar gained. To save money by means that will discourage patronage or that will result in increased expenditures at some future date is poor business.

Usually the first step in reducing operating expenses is to cut the service. Under some circumstances this probably can be done to advantage, but under others it is a dangerous practice. At times when headways are short it may be possible to cut the service and continue to carry the traffic satisfactorily without long waits between cars or serious overcrowding. If cuts are made when headways are already long, the effect will inevitably be to deter people from using the service. A reputation gained now for infrequent service will remain to plague the company long after the present business depression has passed into history. There is reason to expect that in the comparatively near future the

THE PUBLISHERS take pleasure in announcing the appointment of John A. Miller, Jr., as Editor of *Electric Railway Journal*, effective Sept. 1.

Mr. Miller has been on the editorial staff of *Electric Railway Journal* since February, 1923. During the intervening years he has advanced steadily to positions of increasing responsibility and for the past year has been in charge of the editorial conduct of the paper as Managing Editor. His appointment as Editor is a merited recognition of his capacity for editorial leadership. He is qualified for his work by both training and experience, having spent several years in the employ of the Public Service Railway of New Jersey, following his graduation from the course in civil engineering at the Sheffield Scientific School, Yale University.

As a result of Mr. Miller's practical acquaintance with the problems of community transportation and his intimate contact with the field, combined with his experience as a journalist, the publishers look forward with confidence to continued service of a high order to the electric railway industry.

economy of using public transportation will appeal to a considerable number of persons who have been using private automobiles extensively in the past. To discourage this tendency by long headways would be extremely shortsighted.

Another usual method of economizing is to curtail maintenance. Here again it is important that great care should be exercised. Maintenance costs have already been substantially reduced from what they were a few years ago. It may be that further reductions can be made with safety. On the other hand, nothing is gained in the long run by neglecting the proper upkeep of the property. Maintenance practices now in effect were originally adopted because they were considered to be economical. If this idea was right then it is unlikely that money can be saved by abandoning the practices now.

Recently a number of railways have attempted to economize by dispensing with the services of certain employees engaged in so-called non-essential work. Certainly their services can be dispensed with if their work really has been non-essential. But it is well to remember that many of the jobs now deemed non-essential were originally created because it was thought worth while to have the work done. If that was true a year ago, the chances are that it is equally worth while to have the work done today.

All this is not to intimate that it is a mistake to reduce operating expenses. Where savings can be made without endangering the future it is highly desirable that they should be made. But it would be a most serious mistake to mortgage the future for the purpose of making a small saving in the immediate present.

St. Louis Should Go Ahead Now

WHETHER or not St. Louis is destined eventually to realize all of the advantages implied by the terms of the report of the transportation survey commission, that report is of more than local interest. For the sake of St. Louis, it is to be hoped that the entire plan may be carried to full fruition, but even if that is not in immediate prospect, some of the proposals should not be remote of realization. Important as is the suggestion contained in the recommendation for the construction of rapid transit lines, that proposal is overshadowed by the more immediate prospects for quick relief contained in other parts of the report.

St. Louis may have to wait for its subways, but there is no reason why it should have to wait over-long to achieve co-ordination of street car and bus service, elimination of parking, rerouting of street cars, elimination of unnecessary stops by street cars, regulation of taxis and the so-called "service cars," co-ordination of traffic control by automatic signals in the business districts, and important street widenings. The recommendation is sound that 800 new cars be purchased, half of the number to be used for replacing cars now operated. This expenditure alone would total $12,800,000. The suggestion that 11½ miles of street railway be constructed confirms the contention of the essentiality of service of this kind.

How the program would be worked out financially is not made plain in the digest of the recommendations so far made public. This, of course, is a most important consideration. As matters now stand in St. Louis, it would be impossible for the local company to meet a capital investment of the kind contemplated unless the continuity of the company financially were assured under adequate franchise provisions.

The ends sought in St. Louis—resulting in greater usefulness of the local transportation system—are the ends the managements of the local transportation agencies in all of the major cities hope to achieve. In many respects, they are civic ends more than they are company ends. No better earnest of faith on the part of the city toward the accomplishment of the purpose of the report could be given than for those responsible for the conduct of the city to proceed at once to put into effect the suggestions for immediate improvement not calling for large capital expenditures.

Principles—Not Details of Regulation Are the Concern of Congress

URGENT need exists for the stabilization of interstate bus operations. That is recognized by almost everyone who has given the matter any serious consideration. The interests of the public, the railways and the bus operators themselves all require it. While the present chaotic situation may work to the advantage of certain irresponsible operators, it is extremely detrimental to those who are endeavoring to give reliable service at reasonable rates.

Before stabilization can be effected, however, the principle of regulation must be legally established. For other types of common carrier transportation service, this principle was established many years ago. That it has not been extended to interstate bus operations has been due to a peculiar set of circumstances, rather than to the existence of any real objection to it. One of the long-established principles of this government is that no one state shall have the right to regulate interstate commerce. It was more accident than design, however, that the law which created the Interstate Commerce Commission restricted its activities to the regulation of rail and water transportation. To correct the situation thus created, legislation has been under consideration by Congress for several years. At the present time the Parker bill, providing for regulation of interstate buses, is on the list of unfinished business of the Senate. When the short session of Congress convenes in December it will come up again for consideration.

The original purpose of this legislation was to empower the I.C.C. to regulate interstate bus operation in the same general way that it has in the past regulated rail and water transportation. For practical reasons it was provided that under certain conditions this authority should be delegated to joint commissions of the states concerned. During the closing days of the past session the Senate committee on interstate commerce made a number of revisions and amendments to the bill as passed by the House of Representatives, which depart entirely from the original purpose. One of these amendments provides for more than one operation on every interstate bus route, thereby not merely permitting but practically requiring competition. Another would prohibit the merger or consolidation of a bus company with a railroad company. Still another amendment has been submitted requiring that no bus operator shall remain on duty for a longer period than eight consecutive hours. Other stipulations proposed are that every bus with a capacity for more than 20 passengers shall have a crew of two men, and that a list shall be kept of the names and addresses of all passengers carried.

Obviously a number of these amendments are entirely impracticable. Doubtless they will be contested on the floor of the Senate and some modifications will be made.

Digitized by Google

They will be subject also to discussion by the joint conference committee of the Senate and the House of Representatives, and it may be hoped that the bill which eventually emerges will be a considerable improvement over the bill as it stands today.

Regardless of the merits or demerits of these amendments, however, it is evident that they do not belong in a law of this kind. Details of regulation are not the concern of the Congress of the United States. That body should establish the principle of regulation of interstate bus operation. Working out of the details can and should be left in the hands of the regulatory commission.

Cleveland's Two-Cent Fare Zone

NO MATTER what the outcome may be, the experiment of the Cleveland Railway with a 2-cent fare in a restricted downtown section is of great interest to the industry. It is not the first effort of its kind to induce riding and to increase the popularity of the service, but it is different from most of the others. In it no account is taken of economic theories about standby or readiness to serve charges about which there has been so much discussion in the past.

Since Cleveland is under a service-at-cost plan it may be assumed that operation at the 2-cent rate will not be permitted to continue if results foreshadow the exaction of a penalty from riders in other areas. That is to say, the service must be self-sustaining if it is to continue. But even if the revenues no more than balance the cost of the service the company would stand to gain under the theory that the greater the number of people served, the greater is the civic usefulness of the railway.

The present 2-cent rate is admittedly an experiment. It is hoped that from operation under this plan data will be garnered sufficient to settle conclusively whether the proponents of the idea are right in the claims they have set up for its efficacy. The extent to which the people of Cleveland ride in the 2-cent zone would appear to be the only answer to that. If the answer is convincing the entire industry will stand to profit, not because the plan would be generally applicable, but because under conditions comparable to those in Cleveland, the zone system may offer a means of increasing the usefulness of local transportation systems.

Key System on New Financial Basis

DETAILS of the terms of the recent reorganization of the Key System Transit Company are of interest primarily to the holders of the securities of that company, but what was sought to be accomplished is of interest to the entire electric railway industry. The Key System succeeded the San Francisco-Oakland Terminal Railway. Things went fairly well with the company for a while, but then it fell upon evil days. At its promulgation the financial structure of the Key System appeared to fit the needs, but it was subsequently found to be awkward and inflexible. Mortgages containing onerous restrictions soon proved burdensome, a large floating debt accumulated and net earnings eventually were insufficient to meet the fixed charges on $20,000,000 of funded debt. In short, the company suffered not only from external troubles in the way of declining earnings, franchise burdens, excessive taxation, and other difficulties, but also from a set of internal troubles that could only be cured by a readjustment of the financial structure.

In the new financial set-up the reorganizers have gone even farther than was contemplated would be necessary by the committee of the American Association that some years ago reported on such readjustments. In a sense, the matter of physical valuation has been ignored. The effort appears to have been to bring the new financial set-up within the prospects of present earning capacity. This would seem to run counter to generally accepted theories, but those responsible for the reorganization apparently saw no other way out. Funded debt has been cut $15,500,000. The mortgages covering the properties have all been removed. As matters now stand, all of the present funded debt of $4,500,000 is in the form of equipment trust certificates. That debt is less than 18 per cent of the rate-making value. Not only that, but under the terms of the sinking fund of the new $3,500,000 equipment trust issue the company has the option of delivering to the trustee certificates of either the old or the new equipment trust issue, to meet the $431,250 of annual maturities. In other words, the sinking fund may be used to support the market. The previous equipment trust issue of $1,025,000 remains undisturbed.

The new system starts out apparently assured beyond peradventure that all its obligations can be met. That, of course, is propitious. Security holders of the old company now are remote from anything like a fixed lien on the properties of the successor company, but the financial housecleaning, while drastic, holds out hope that eventually the present junior securities may work into a position of real worth. If they do, then those who have just made the present sacrifice will not have done so in vain.

Hitting Them in the Pocketbook

ONLY a gifted satirist could do full justice to the left-handed compliments which successful merchants frequently pay to the local transportation agencies. Again and again these men have tickled our risibilities and brought crocodile tears to our eyes by their agitation at the prospect that traffic by organized transportation agencies might possibly be removed from the streets on which they have the emporiums. While they felicitate each other on their acumen and the extent of their worldly success at the chamber of commerce meetings, Rotary Club lunches or wherever it is that such men gather, they seldom give a thought to the organized transportation agencies. But let it be even hinted that the transportation lines are to be diverted from their stores and they are not the same men. They then see nothing ahead but dark disaster.

Now to hold that these merchants owe their entire success to the accessibility of their stores to the transportation lines would not be warranted. That they do owe a large part of their success to such accessibility, however, has been established beyond a shadow of doubt. Else why would they become so panicky at the suggestion of diverting traffic away from the front of their stores? It is a nice compliment these merchants and tradesmen, big and little, pay to the organized transportation agencies by the vehemence of their opposition to practically all suggested traffic rerouting. But it would be better still if their concern for the welfare and the continuity of the local transportation service and its conduct on a profitable basis began to manifest itself before the prospect arose of their having their own pocketbooks flattened.

Service in Mobile is given by rolling stock maintained at a high standard. Thirteen new cars similar to the one in the foreground have been purchased in the past three years

Mobile Bids for Patronage with

Clean Cars, Close Headway *and* Smooth Track

By

CLIFFORD A. FAUST

Assistant Editor *Electric Railway Journal*

CITIES with a population of 100,000 and under are passing through a crucial period of their transportation history. No one denies this fact. Studies of their problems over the past two years by the small-city committee of the transportation and traffic association have revealed a number of common causes for their troubles. Unsatisfactory financial set-ups, competition from the privately owned automobile, a trend toward walking when service is not sufficiently frequent, inadequate fares, excessive taxation and other burdens, a feeling that the street car is an obsolete form of transportation and competition from unregulated taxicabs and jitneys have all contributed in some measure toward the present difficult situation.

To combat these unfavorable factors many cities have made real and definite progress. By frank and open discussions they have secured relief from unreasonable franchise requirements, they have modernized their rolling stock as extensively as possible, they have improved service by speeding schedules and operating as many cars as the traffic will justify, they have intensively cultivated public relations and by modern merchandising methods and active solicitation of patronage have made real progress. And their efforts have not been in vain. Almost every small city that has assumed an aggressive attitude in meeting its problems has improved its status.

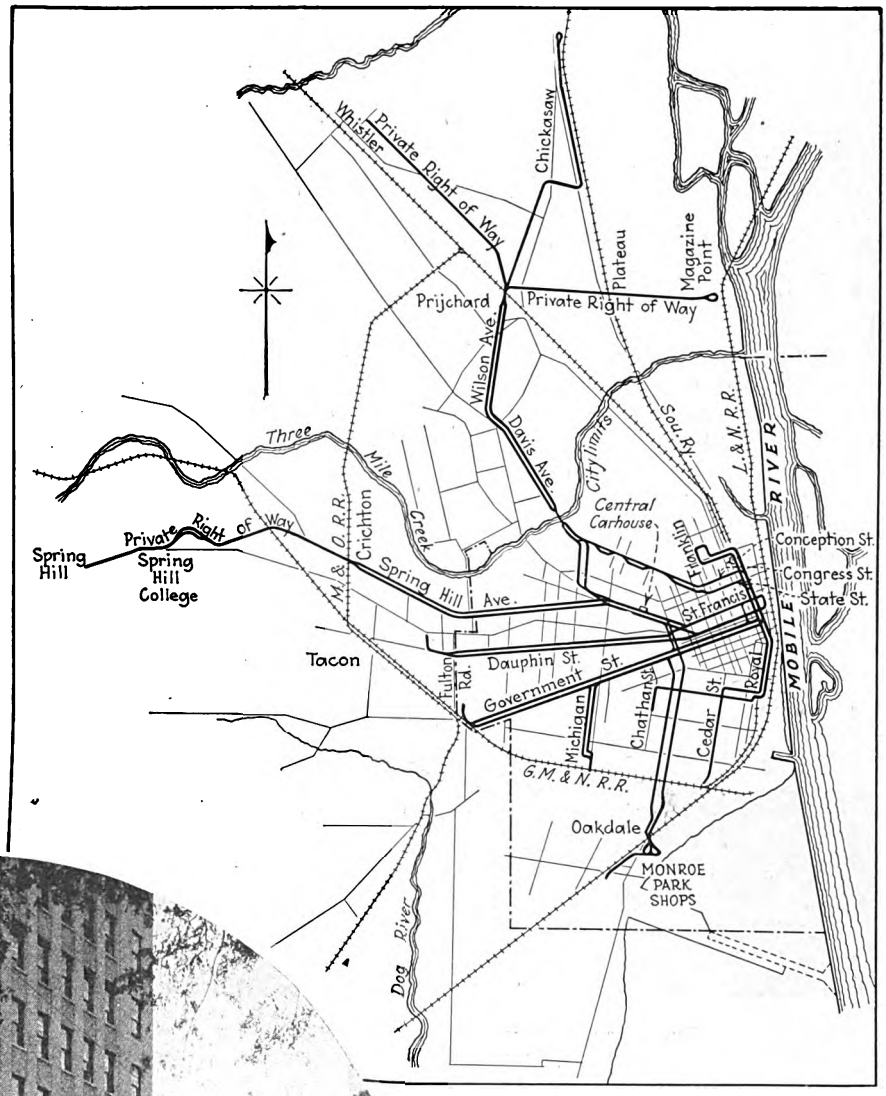
In the southern part of Alabama, one of these cities is doing many notable things not only to retain its prestige but also to move definitely forward. It is Mobile, a city of approximately 75,000 population, and served by an independent electric railway, the Mobile Light & Railroad Company.

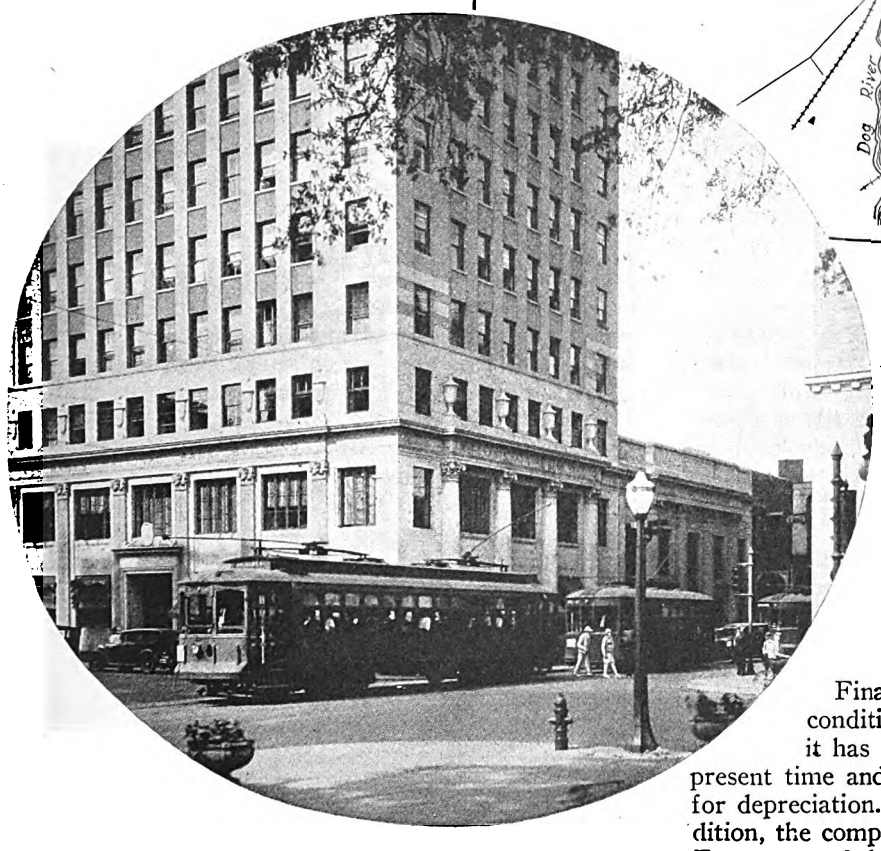
Digitized by Google

Extensive rehabilitation of physical plant, accompanied by many other steps to improve service and better public relations, has placed the system in a favorable position

An analysis of the local transportation situation in Mobile reveals that many of the unfavorable factors present in most small cities also exist there, but that the railway has singled out each individual one, and, through careful studies of the problems, has taken definite steps to solve them.

Among the favorable aspects of the Mobile situation, however, there is one which stands out above all the rest. It is the unbounded optimism of the management and the excellent *esprit de corps* all through the organization. Both J. H. Wilson, president of the company, and F. F. Rossman, vice-president and general manager, have faith in the city of Mobile and in the transportation system they manage. They know that Mobile is an industrial city, that the South is making great strides in its industrial activity, that the city is growing steadily and that a reliable system of transportation is a vital part of this great center. They have faith in the city to the extent that they are continually improving the railway service. This same spirit is apparent in the other officers of the company, in the shop employees and in the men on the cars.





Eleven lines of the Mobile Light & Railroad Company effectively serve all parts of the city. The three lines to the north and the Spring Hill line to the west have private rights-of-way in the suburban areas

At left is a view in the business district of the city showing one of the double-truck cars used for suburban service and two city cars

Financially the company is in very sound condition. It has never been in receivership, it has only a small bonded indebtedness at the present time and has allowed a large amount each year for depreciation. In retaining this sound financial condition, the company has not neglected its physical plant. Every part of the system has been well maintained.

Only recently the company received seven new single-truck cars of modern design. This order followed one for six cars of a similar type which were placed in service 2½ years ago. All of the other cars are kept in as attractive condition as possible. The rolling stock of the company is painted and overhauled every 30 months, so that the cars always present a good appearance.

Digitized by Google

One of the greatest assets of the company is its extensive mileage of new track and the small mileage of single track on city lines where two-way operation is necessary, 0.75 mile, to be exact. The city of Mobile has been repaving its important arteries over the period of the past eight years and has included almost every street on which the electric railway has car lines. In all of this work the company has joined in rebuilding its track with a smooth, permanent type of structure. Its power distribution system, likewise, has been modernized.

Particular pride is taken by the company in its maintenance facilities and standards. A modern car shop; a well-arranged carhouse, equipped for light repairs; the use of the work order system of maintenance; the establishment of high standards, and the employment of an experienced and interested group of shop men have all contributed to the improvement of the equipment and the reduction of maintenance cost.

Another favorable factor for the company is that it is faced with no bus, jitney or taxi competition. A

The executive offices and trainmen's quarters are located in this building on Spring Hill Avenue. The well-arranged carhouse at the rear is designed for storage and light repairs

few interurban bus lines serve the city, but they are not permitted to carry local traffic.

Even though the company does not have any mass vehicle competition, it has altered its routes to serve the city more efficiently and to eliminate any duplication of service. By abandoning certain short portions of its route and building new track, it has eliminated unnecessary mileage, without impairing the service.

Fast Schedules Maintained on All Lines

On three lines, extending into suburban districts on the north, and on one line extending west, private right-of-way is used. High-speed, limited service is given at frequent intervals on these lines and schedules distributed to inform the patrons of the leaving times. One of the limited cars on a county line makes only four stops in the outlying district and then runs express the remaining distance. On the 7-mile trip ten minutes is saved. With this schedule the car reaches the city in less time than automobiles. Business has increased to such a volume on this line that the company is considering adding trailers. On all its lines, the company is maintaining as close a headway as possible. To accomplish this it is steadily increasing the number of car-miles and car-hours operated. Last year, for example, the company operated 2,180,412 car-miles, as compared with 2,160,525 in 1928, an increase of 19,887. Car-hours in 1929 were 1,223 in excess of the number operated in 1928. The management realizes that in a city the size of Mobile a great number of people walk to the business center if a car is not in sight, and therefore offers the maximum service to the public. The importance of this is emphasized by the fact that the maximum ride in Mobile is 24 minutes and the average ride is approximately 15 minutes. Studies of traffic and walking distances are constantly being made by the company to ascertain whether or not the schedules are satisfactory. Rush-hour headways on residence lines now range from 5½ to 8 minutes. Along with shortening headways the company has increased its schedule speeds. City lines now average 8.92 m.p.h. and county lines 11.50 m.p.h.

At present the company receives an 8-cent cash fare and sells four tokens for 30 cents. During 1929 the average fare per revenue passenger was $0.0753. This figure is the result of a steady increase in the fare over a long period of years.

Two very valuable assets of the company are its excellent public and employee relations. The company boasts of a very clean court record, evidence of the favorable attitude of both the public and the attorneys toward the electric railway. Special care is taken in answering inquiries of patrons and giving consideration to suggestions that are sent in. The company also advertises civic events and programs of numerous organizations on its cars.

Employee relations in Mobile are exceptionally good, no major labor troubles having developed. Group insurance is offered to those employees who desire it. Although no extensive safety campaign has been conducted, talks on the subject are given frequently enough to keep the employees alert to the dangers of careless operating. This is stressed not only for the operators, but also for all the other men employed. The company has made its Monroe Park shop almost 100 per cent safe by proper installation of machines and use of many safety devices.

At regular intervals talks are given the trainmen on neatness, courtesy, efficient operation and merchandising. These have aided considerably in improving the work of the men and in stimulating them to sell the service.

Every attempt is being made by the company to lower its operating expenses. A gradual change-over from two-man to one-man operation has taken place, so that at the present time only two county suburban lines are using two men. A detailed analysis of all expenses by departments is made monthly and followed by lectures to the superintendents on ways and means of reducing costs.

Digitized by Google

The superintendents, in turn, instruct their men in a similar manner. By careful purchasing and paying for all materials and supplies outright the company has been able to reduce costs to a minimum.

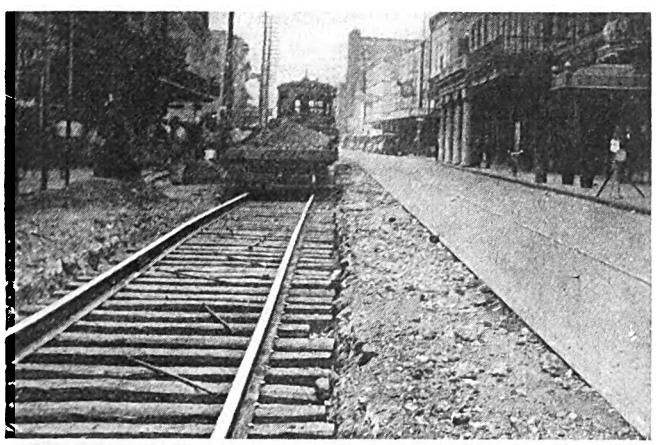
Probably the biggest handicap to the Mobile railway system is the psychology of the public with regard to riding on street cars. Although in several parts of the country this feeling has developed, probably in no part has this psychology developed to such a detrimental state as in the South. Mobile, like many other cities in the southern states, has suffered a loss in riding partly because of this attitude. Of course, the private automobile is the greatest competitor of the railway and is responsible for much of the shrinkage in patronage. It has harmed the railway not only in removing the actual drivers from the street cars, but also in picking up prospective patrons and in congesting the downtown streets, slowing up car movement. A rather unusual problem of the company has been the necessity to rebuild track which was in excellent condition. It is likely that the company will have heavy paving burdens for the next ten years.

Thirteen New Cars Purchased

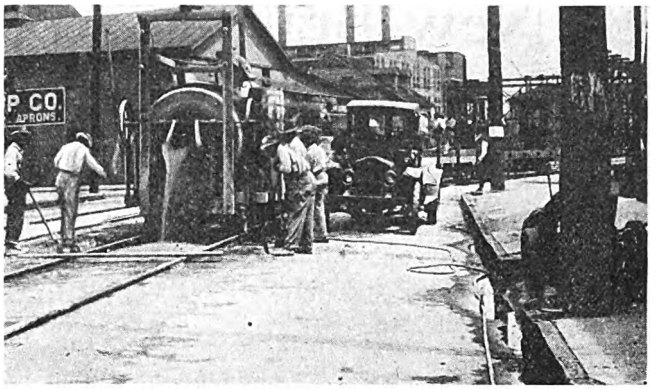
In its program of rolling stock modernization the Mobile Light & Railroad Company bought six single-truck, Birney one-man cars in 1927 and seven more in April of this year. Of the latter order four were built by the Perley A. Thomas Car Works, High Point, N. C., and three by the American Car Company, St. Louis, Mo. The cars seat 33 passengers, weigh 20,500 lb., are equipped with all safety devices and are designed for double-end operation. Double folding doors at the front, an exit at the rear for colored patrons and a very wide aisle permit a rapid exchange of passengers. The wide aisle has the great advantage of allowing the colored patrons entering the front to pass the white passengers without contact.

In the past seven years the railway has rebuilt approximately eight miles of track. By years the reconstruction was 1.444 miles in 1923, 0.982 in 1924, 0.2699 in 1925, 0.547 in 1926, 0.756 in 1927, 0.885 in 1928 and 2.943 in 1929. For 1930, the figure will total about 0.818 mile. Only 2.355 miles of streets with car tracks within the city limits remain unpaved. It is expected that within the next year or two they will be hard surfaced also.

A very interesting type of construction has been employed in rebuilding all of the company's tracks. A 6-in. coarse slag ballast is surfaced with a 3-in. layer



An extensive program of track rebuilding during the past eight years has included a large proportion of the city lines



Pouring concrete over the ties, preparatory to laying the paving surface

of fine slag ballast. On this 7 in. x 8 in. x 8 ft. creosoted pine ties are laid on 2-ft. centers. Dirt is filled in on top of the 3-in. layer to the top of the ties, extending the full width of the ties. This is well tamped and then covered with a 5 or 6-in. layer of concrete, the depth depending on the type of paving surface used. An outstanding feature in the construction is the pouring of concrete underneath the rail section between alternate pairs of ties, made integral with the top layer of concrete. The slabs are 16-in. wide and extend to the same depth as the ties, 7 in. This type of construction ties the base definitely to the rail, so that if there is any movement the pavement and rail will move together. As a result no paving breaks have occurred or are anticipated. T-rails of 82-lb. section, 7 in. in depth, or 7-in. girder rails of 103 or 122-lb. section are used in the construction. The company has approximately 4,400 Thermit-welded joints at present and is expanding this number, as all new construction will have this type of joint.

Work Order Maintenance System Effective

Much of the effectiveness of the shop department is due to the use of a work order system. Before any maintenance can be performed a work order sheet must be filled out, stating the nature of the work, the materials required and the estimated cost of both materials and labor. The system has aided materially in reducing costs and in improving the efficiency of the shop employees. All cars are inspected on a 1,000-mile basis and completely overhauled and painted every 30 months at the Monroe Park shop.

An efficient layout at the Central carhouse reduces car movements to a minimum and permits rapid storage and dispatching. Sixteen tracks, extending the full length of the yard, are served by a single ladder track at each end. These ladders are so joined to the two tracks on the adjoining avenue that one can serve as an entrance only and the other as an exit. Eight of the tracks pass through the carhouse and have 172-ft. pits for inspection and light repairs. Fronting on Spring Hill Avenue is the main building with the company's offices, trainmen's quarters and a shop.

Summing up the situation in Mobile, we find that it has problems similar to those encountered on other properties of comparable size, and that it is taking definite action to combat them. The company officials have an optimistic outlook, the financial condition of the company is sound, its rolling stock is well maintained, its track is in large part new, the service has steadily been improved and the company enjoys an excellent state of relations with its public and employees.

New Braking Apparatus Demonstrated

BEFORE a group of more than 50 electric railway officials and manufacturers from all over the country, a demonstration was given on Aug. 14, at Pittsburgh, Pa., of a new type of braking apparatus developed by the Westinghouse Traction Brake Company. This apparatus, called a "traction booster," was installed experimentally on car No. 4936 of the Pittsburgh Railways. It combines features of the familiar air brake and of the magnetic brake, and, at the same time, overcomes some of the limitations of those two systems. While the air brake is extremely flexible it is limited in over-all effectiveness by the adhesion between wheel and rail, so that, under the most favorable conditions, the stop obtained with a street car is about two to three times as long as the best automobile stop. The magnetic track-shoe brake to a certain extent is less dependent upon rail friction, and, when used in conjunction with an effective air brake, provides a shorter stop than can be obtained with the air brake alone. The main limitations of the track-shoe brake are its relative inflexibility and the high maintenance of its track-shoe mechanism.

The "traction booster" consists of two magnets on each truck which are spring-suspended $\frac{5}{8}$ in. above the rail. When the brake cylinder pressure exceeds a predetermined value, a switch is automatically closed, thus energizing the magnet coils. The magnets do not come in actual contact with the rail, but exert a magnetic pull on the rail which, in effect, increases the weight of the car. The increased adhesion between wheel and rail, resulting from the magnetic pull, permits the use of a higher retarding force without danger of wheel sliding. On the demonstration car, which weighs approximately 44,000 lb., the magnetic effect amounts to 6,000 lb. per truck, a total of 12,000 lb., which represents an increase in adhesion of 28 per cent. The booster itself produces little retarding effect, its function being to increase the adhesion to such an extent that higher brake cylinder pressures can be used safely. In this way, the full flexibility of the air brake is retained, and the higher rate of retardation made possible by the booster need not be used unless desired.

In the tests, stops were made at retardations of 4 m.p.h.p.s. without the booster and 8 m.p.h.p.s. with it. Those at 4 m.p.h.p.s. were intended to show what can be accomplished through present standard air-brake devices, with some consideration for the truck and car body members with respect to ability to withstand the forces employed. For this purpose a braking ratio of approximately 138 per cent was used.

The stops accomplished at a retardation rate of 8 m.p.h.p.s. required the assistance of the traction booster. The braking ratio was 275 per cent, based on the actual car weight of 44,000 lb. and was approximately 215 per cent based on the effective weight of 56,000 lb. The practical use of a braking ratio of 215 per cent was possible because of the fact that the rails were sanded and a retardation controller was employed to reduce the peak of retardation which occurs at the instant of stopping.

The retardation controller consists of a cylindrical weight moving freely between rollers in a tightly sealed case, but held in balance or neutral position by opposing springs at each end. If the retardation exceeds a predetermined value the weight moves, and in doing so opens a valve which in turn reduces brake cylinder pressure. The friction characteristics of cast-iron brakeshoes are such that unusually high friction occurs at very low speeds, such at at the instant of stopping. This causes a surge or jerk in the car, and in view of the unusually high forces employed, would be objectionable unless controlled in a manner as indicated.

Results of these tests are shown in the following table:

Results of Braking Tests without and with Booster

Retardation of 4 M.P.H.P.S.				Retardation of 8 M.P.H.P.S.			
Speed M.P.H.	Dist. Feet	Time of Stop Sec.	Ret. M.P.H.P.S.	Speed M.P.H.	Dist. Feet	Time of Stop Sec.	Ret. M.P.H.P.S.
10	20	2.4	4.1	10	13	1.3	7.7
20	65	4.6	4.3	20	41	2.4	8.3
30	160	7.2	4.2	30	93	3.6	8.3

The apparatus installed on the demonstration car is in purely experimental form and does not represent a commercial design. It was demonstrated merely to show the possibilities of equipment with retardation rates of 8 m.p.h.p.s., as well as the effect on car body and trucks of these high retarding forces necessarily applied, viz., a braking ratio of 275 per cent.

Guests attending the braking demonstration were also afforded an opportunity to inspect car No. 4731, which has been equipped with a new type of trucks. These trucks have been developed jointly by the Westinghouse Company and the Pittsburgh Railways. They are designed for four 50-hp. motors, WN drive, and 22-in. wheels. Dynamic braking is provided, as well as air-operated drum brakes on the axles. The truck members are welded together, and a substantial saving in weight has been effected.

A.I.E.E. to Revise Standards for Control Apparatus

STANDARDS for railway control apparatus have been made the subject of a report issued by the standards committee of the American Institute of Electrical Engineers. This is a tentative revision of the present Standard No. 16 printed under date of July, 1925. The report is not considered by the committee as being final, but is presented with the hope of obtaining opinions, criticisms and suggestions of all parts before it shall be approved.

The report presents the accepted definitions of all control apparatus and equipment as used under specified service conditions. It follows with the standard definitions of the various kinds of ratings and the manner in which they should be expressed. Temperature limitations of coils, resistors and other parts, and, also, limitations other than those due to heating are defined. The report also describes the various classes of insulation and the standard methods of making temperature determinations and dielectric tests.

The principal changes suggested in this report concern the definition of the limits of temperature rise for coils and mechanical parts, and the determination of the mean temperature of a copper winding by measurement of its resistance when the resistance at some reference temperature is known.

Trolley buses on Central Avenue, Chicago, are operating more than 3,000 miles and carrying nearly 30,000 passengers per day

Operating Statistics Prove

Success of Trolley Buses

in Chicago

Popular approval has warranted extension of this type of service. New equipment recently ordered will bring total number of vehicles to 70. Schedules, traffic and operating costs discussed in a paper presented before the Wisconsin Utilities Association.

By

F. A. FORTY

Superintendent Schedule and Traffic Department
Chicago Surface Lines

RECENT rapid developments in trolley bus design have placed this vehicle beyond the experimental stage. The developments in light-weight, high-speed motors, automatic control, large capacity light-weight bus bodies equipped for circulating loads, pneumatic tires and excellent riding qualities have made the trolley bus a vehicle which is headed towards widespread adoption. The successful installation of the trolley bus in Salt Lake City, the more recent large scale installation in Chicago and elsewhere have demonstrated that this vehicle has great possibilities in the transportation field.

Trolley bus service was first inaugurated in Chicago on the Diversey line in the northwest section of the city on April 17, 1930. Additional trolley buses were subsequently placed into operation in the same section of the city on the Central Avenue, Narragansett Avenue and Elston Avenue lines on June 8, June 29 and July 1, 1930, respectively. These operations, together with the operation of three lines using gasoline buses, were the result of a decision by the Illinois Commerce Commission dated March 6, 1930, directing the withdrawal of Chicago Motor Coach Company buses from the northwest section of the city and directing the Chicago Surface Lines to establish bus service as extensions of its rail lines in this territory.

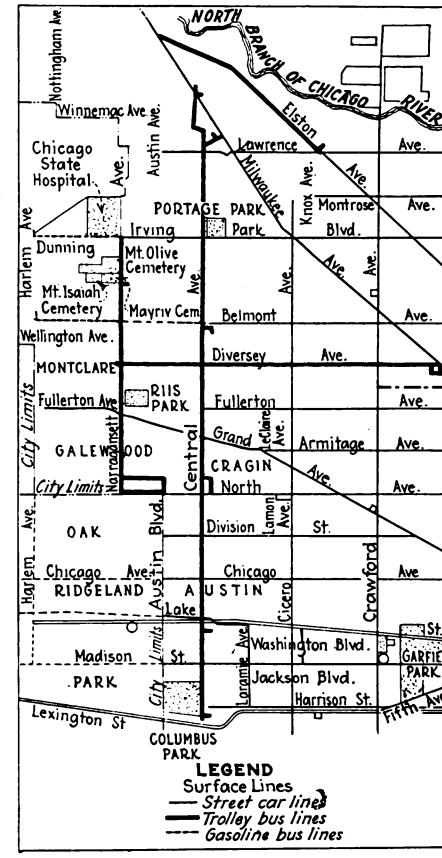
The original order for trolley buses totaled 41 vehicles, of which 29 were built by Twin Coach Corporation, six by Brill-American Car Company, and six by the St. Louis Car Company. Within a few weeks after service was started, additional trolley buses were needed and the fleet was increased to 55 by the purchase of seven Twin Coaches and seven Brills. Recently seven more

Digitized by Google

Twin Coaches and eight Brills have been ordered. This latest order will be delivered in September and will bring the total number of trolley buses operated in Chicago up to 70.

Diversey route, 3.81 miles in length, is operated over a fairly wide street with new pavement. Approximately 1 mile of the route was formerly served by a one-man rail car line. The present bus route intersects two important rail trunk lines and taps the Milwaukee Avenue line, which is the most important and heaviest rail trunk line on the northwest side. A wye at the west end and a loop at the east end serve as terminals. The line does a thriving business, inasmuch as 19,400 riders are handled on a normal weekday. The average number of riders carried per vehicle-mile amounts to 9.58, while the average number per vehicle per day amounts to 1,140. Seventeen trolley buses are required to operate the line. A 2½-minute headway is operated during the rush hours, when the maximum passenger flow reaches 1,370 in the heaviest half hour. A 6-minute headway is maintained during the base, and a 6⅔-minute headway during the evening. In spite of the difficult conditions, relatively high speeds are maintained. The speed between terminals ranges from 11.72 m.p.h. during rush hours for the direction of heaviest travel to 13.05 m.p.h. during the base. The all-day speed between terminals is 12.33 m.p.h.

Central Avenue route, which is 6.98 miles in length, is an important north and south line arranged with wyes at both terminals. Poor pavement in the north section where an 18-ft. strip in the middle of the street has been left unpaved, a narrow bridge with a 17-ft. roadway, and a 1.75-mile stretch of rough pavement where the roadway width is only 28 ft., have all imposed severe operating conditions on this line. The route does a large volume of business, carrying 29,500 riders on a normal weekday. The density of riding is quite high, since the rides per vehicle-mile amount to 9.45. Twenty-five trolley buses are required to operate the line during rush hours, when a 3.15-minute headway is maintained. A 6.4-minute headway is maintained during the base and a 7¾-minute headway during the evening. The speeds maintained between terminals are relatively high, considering the poor pavement and narrow street widths. The speed ranges from 11 m.p.h. during rush hours for the direction of heaviest travel to 11.97 m.p.h. during the evening. The all-day speed is 11.47 m.p.h.



Four heavy-duty extensions to rail service are being successfully operated with trolley buses in the northwest section of Chicago

The number of riders carried per vehicle-mile on these two lines shows that the service is well patronized. The 40-seat buses used on both lines are used to full seating capacity at the heaviest loading points along the line during non-rush periods. During rush hours the average number of passengers per bus at the heaviest point along the routes is now 60. The additional buses to be acquired for these routes will reduce this to 55, which is a more satisfactory rush-hour standard. The wide double door for the front entrance and exit and the rear door exit permit effective circulation of passengers. On the Diversey bus route the average length of stop is short, varying from five seconds during the midday to 7.2 seconds during rush hours. The rear door exit is used to great advantage during the rush hours, as 25 per cent of the total passengers alighting use this exit. Street men also use this exit door for loading passengers at concentrated loading points.

Operation of the trolley bus in Chicago has shown that this vehicle is capable of easily maintaining speeds

Operating Statistics of the Chicago Trolley Bus System

	Diversey Avenue	Central Avenue	Narragansett Avenue	Elston Avenue
Distance between terminals	3.81 miles	6.98 miles	3.50 miles	2.86 miles
Number of buses used during morning rush	17	25	6	4
Number of buses used during base	7	13	5	3
Number of buses used during afternoon rush	17	25	6	5
Number of buses used during evening (8 to 10 p.m.)	7	13	5	3
Average inbound morning headway in maximum half hour	2.50 minutes	3.15 minutes	6.75 minutes	7.25 minutes
Average headway during base	6.00 minutes	6.40 minutes	8.00 minutes	9.00 minutes
Average outbound afternoon rush headway in maximum half hour	2.65 minutes	3.15 minutes	6.75 minutes	6.00 minutes
Average headway during evening (8 to 10 p.m.)	6.66 minutes	7.75 minutes	7.80 minutes	9.00 minutes
Scheduled speed inbound during morning rush	11.72 m.p.h.	11.00 m.p.h.	11.66 m.p.h.	13.70 m.p.h.
Scheduled speed outbound during morning rush	13.05 m.p.h.	11.33 m.p.h.	12.72 m.p.h.	14.90 m.p.h.
Scheduled speed inbound during base	13.05 m.p.h.	11.65 m.p.h.	12.72 m.p.h.	14.90 m.p.h.
Scheduled speed outbound during base	13.05 m.p.h.	11.65 m.p.h.	12.72 m.p.h.	14.90 m.p.h.
Scheduled speed inbound during afternoon rush	12.70 m.p.h.	11.33 m.p.h.	12.72 m.p.h.	14.90 m.p.h.
Scheduled speed outbound during afternoon rush	11.75 m.p.h.	11.00 m.p.h.	11.66 m.p.h.	13.70 m.p.h.
Scheduled speed inbound during evening	12.70 m.p.h.	11.97 m.p.h.	13.10 m.p.h.	14.90 m.p.h.
Scheduled speed outbound during evening	12.70 m.p.h.	11.97 m.p.h.	13.10 m.p.h.	14.90 m.p.h.
Scheduled speed all day	12.33 m.p.h.	11.47 m.p.h.	12.64 m.p.h.	14.38 m.p.h.
Maximum hourly passenger flow during morning rush	1,370	1,257	455	280
Maximum hourly passenger flow during afternoon rush	1,370	1,235	433	665
Total daily rides	19,398	29,533	6,362	4,426
Total daily vehicle-miles	2,026	3,128	1,102	841
Average number of rides per route-mile per day	2,544	2,114	910	774
Average number of rides per vehicle-mile	9.58	9.45	5.78	5.26
Average number of rides per vehicle per day	1,140	1,284	1,060	886

Digitized by Google

of 12 m.p.h. on busy routes in outlying territory. Speeds as high as 15 m.p.h. can be reached where the density of travel is not too great and where operating conditions are quite favorable. It has been found, however, that this commendable speed performance of the trolley bus does not exceed the speed performance of the modern one-man rail car with the same conditions of operation, volume of business and number of stops per mile.

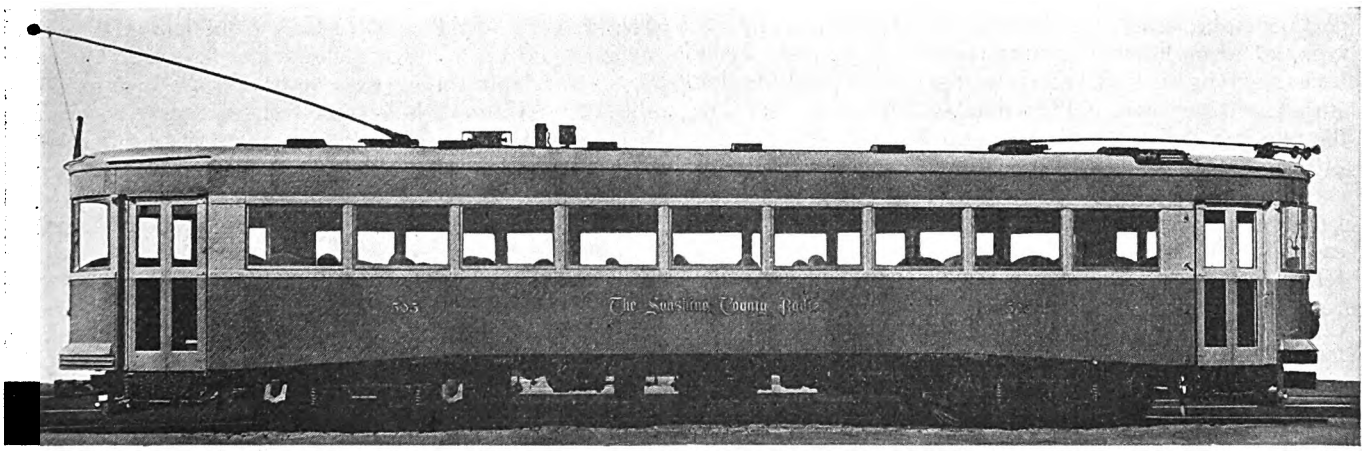
The operation of the trolley bus on our present routes provides a higher quality and a more economical brand of service than would be possible with gas bus operation. The lower energy and maintenance costs on the trolley bus reduce the operating expenses approximately 5 cents per bus-mile. This saving produces a marked operating economy and does much toward wiping out the fixed charges incidental to the investment in trolley structures. On the Chicago system, trolley bus operation will show a saving over gas bus operation on any average headway up to fifteen minutes. At that frequency the total cost of operation for the two forms of transportation will be the same.

Introduction of the trolley bus in the transportation field has aroused a great deal of speculation as to where and when it should be used. No ready formula can be set up to determine its adaptability on any route in any city. Individual routes within a given city vary greatly in the volume, character and distribution of the riding throughout the day. Transportation companies differ from one another in standards of service, construction standards, labor costs, and in working agreements with the trainmen which affect the cost of operation to a great extent. The trolley bus can be used in a very large city only to a limited extent. On our property, 82 per cent of our total car service is rendered on lines where the rush-hour traffic requires a rail car headway varying from 2½ minutes down to one-half minute, and a non-rush hour headway varying from six minutes down to two minutes. Modern rail car operation on this 82 per cent of the system gives better and more economical service than would be possible with the trolley bus.

Probably the trolley bus will play an important part in the local surface transportation system of many cities. In a large city it can be used to supplement the rail car operation by serving outlying and other districts where the volume of traffic will not support rail car operation. In medium-sized cities it can be used to supplement principal rail car arteries and serve outlying districts. In smaller cities it may be more economical to serve the principal routes with trolley buses and the outlying routes with small-capacity gas buses.

Modern Design

Features Windsor Cars



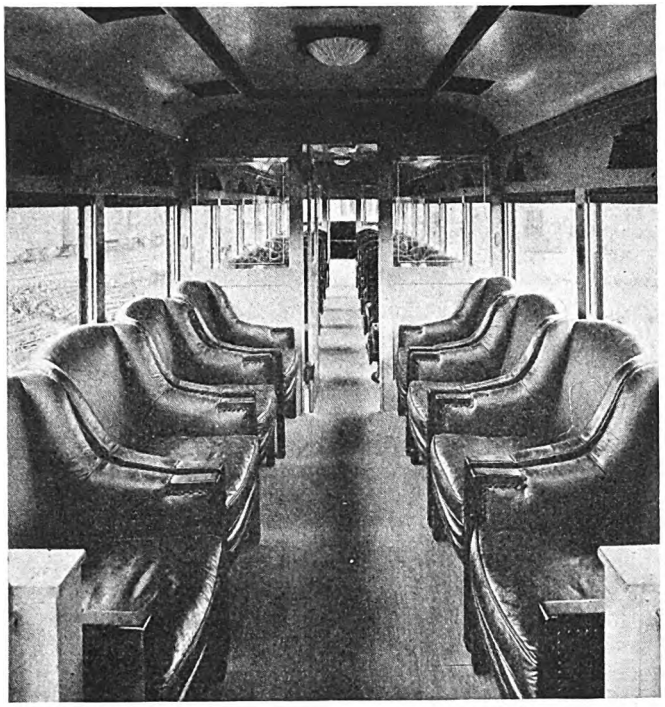
Attractive features are found in the motor and trailer cars just delivered to the Windsor, Essex & Lake Shore Railway

FOUR motor cars and a trailer of special design have just been put in service by the Windsor, Essex & Lake Shore Railway, operated under the supervision of the Ontario Hydro-Electric Railways. These cars, which include the most advanced design of interurbans in Canada, represent to a large extent the ideas of W. R. Robertson, general superintendent, working in conjunction with the Ottawa Car Manufacturing Company.

The bodies of the five cars are of the same dimensions, being 51 ft. 2 in. long over anti-climbers and 37 ft. 8 in. over body corner posts. The width over side sheathing is 8 ft. 3⅛ in., and the width over vestibule corner posts is 7 ft. 7⅜ in. From the rail to the top of the roof the height is 11 ft. 2⅜ in., and from the rail to the top of floor it is 3 ft. 5 in. The framing is of steel.

The motor cars are arranged for double-end operation, being fitted with an electro-pneumatically operated door and folding step at each corner. There is a main compartment with 40 seats and a smoking compartment with ten seats. In the main compartment the seats are arranged transversely on each side of an 18-in. aisle. They are of the semi-individual bucket type, upholstered in plush. All except the end seats are reversible. In

Digitized by Google



Observation compartments of the new Windsor cars are luxuriously furnished

the smoking compartment, on each side of the aisle, there is a leather-upholstered settee for five. The lighting is by ceiling dome fixtures along the center line, five in the main compartment and two in the smoking room.

The design of the trailer is special. It has seats for 50. There is a central main compartment with 28 seats, and at each end an observation room which, including the vestibule, is about 15 ft. long. The side window sash are 42 in. long by 30 in. high. In the main compartment the seats are of the semi-individual bucket type, of deep double spring construction, with 24-in. backs, arranged transversely. They are plush upholstered. At one end of the car tables are placed between the two end seats and the adjoining ones.

The observation room, or solarium, at one end of the car has on each side a settee with plush-upholstered seats for five. The room at the other end of the car has on each side four large chairs upholstered in plush, and a settee upholstered in hand-buffed Spanish leather conforming to the semi-circular vestibule end.

In each motor car the operator's compartment is partitioned off from the main body of the car, and there is a wood and glass partition between the main compartment and the smoking room. In the trailer both observation compartments are partitioned off from the main compartment.

The cars have interior finish of birch mahogany, and the exteriors are finished in blue with yellow trim.

The motor car trucks have 33-in. wheels carrying 100-hp. Westinghouse motors. HL control is used, the controller being lowered to the floor at the operator's position so as to bring the top to a convenient height.

Considerable thought was given to the design of the cars to secure good appearance, comfort for passengers and economy in operation, and to afford the road's patrons something original in the way of passenger equipment. The design provides a pleasing appearance, with the streamline effect much in evidence. The large windows and the window guards arranged to drop into pockets in the car sides add to the appearance. Vestibule door openings have a set of double doors for the winter season. Both inside and outside doors are operated by the same engine.

Making Sleep Easy on the Interstate

MODERN coil spring mattresses have been adopted as regular equipment for lower berths on the all-steel sleeping cars operated between Indianapolis and Louisville by the Interstate Public Service Company, thus keeping pace with the latest developments in sleeping car equipment.

The mattresses were especially designed to fit the extra length berths of the Interstate sleepers, which are 4 in. longer than in standard Pullman cars.

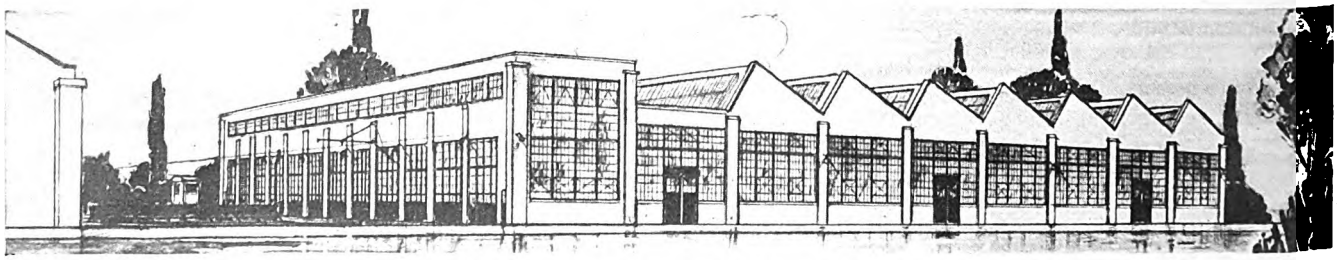
The new mattresses are 4 in. thick and consist of rows of 3-in. coils compressed to a height of 2 in., a layer of woven hair, and a 2-in. layer of hair padding. Each of the coils is set in an individual canvas pocket.

New Shop Unit Begun in Chicago

CONTRACTS for construction of the second unit of the Chicago Rapid Transit Company's shops at Niles Center were let on Aug. 11 and ground broken for the structure on the following day. The first unit, the paint shop, was built three years ago. The new unit, which will cost $375,000, is 200x252 ft. in outer dimensions. It is being built directly south of the first unit at Oakton Street and Hamlin Avenue, and will be used as a construction shop for repairing and remodeling cars.

The building will be rushed to completion as rapidly as possible so that work may be started on remodeling cars to make them suitable for eight-car train operation, the longer trains being necessary when the consolidation with the Surface Lines is effected and the transfer system between the "L" and surface lines inaugurated.

The complete plans for the Rapid Transit Company's shops call for the construction of ten units at a total cost of $4,500,000, covering an area of ¼ mile square. When all completed the shops will be capable of handling a total of 4,500 cars, with a storage capacity in the yards for 350 cars.



Architect's drawing of the second unit, recently started, of the Chicago Rapid Transit Company's Niles Center car shop

UTILITY VALUATION

Demands Logical Treatment

Physical property is the basis of the utility, and its real value fluctuates but little in its ability to render service. Its value in terms of the dollar, however, changes with purchasing power and must be determined from time to time

By

JOHN W. BURKE

Consulting Engineer
New York City

UNDER our law, rate making is a function of the legislative branch of the government. Rates must be made by authority of the State legislatures or of Congress. Although in the early days there were numerous cases in which the legislatures and the incorporators of new utility companies agreed on the rates to be collected and had them expressed in the charters, it soon became manifest that the legislatures could not themselves arrive at fair rates, and especially that they could not directly exercise their power to supervise and regulate the public utilities. Hence, about the beginning of this century, many of the states organized public service commissions, and those which formerly had them increased their scope, so that for years past these commissions have administered the duties of regulation and rate making through the powers delegated to them by the legislatures.

This work of the commissions has proved to be as difficult as it is important. Some may permit too large a depreciation reserve in those prosperous utilities that can collect it. On the other hand, they are sometimes inclined to adopt a method of valuation which confiscates a portion of the company's property in arriving at a rate base. This error is due to a misconception of World War effects. The popular impression is that one effect was to increase costs, whereas the real result was to depreciate the currency. Bearing in mind the purchasing power of the dollar, only a few items of construction or equipment cost substantially more now than in the decade before the war, but this fact is not generally recognized.

Just as real wages differ from money wages, so do real costs of construction differ from the costs in current dollars. Even when money wages are constant, real wages may fluctuate considerably from adventitious causes, such as climatic conditions affecting wheat and other food supplies, and speculation in various commodities. Not so with real construction costs. They have a unique record of stability.

Real cost of construction, outside of engineering, legal and overhead costs, is properly measured in foot-pounds of energy expended by manual labor, machinery or fuel. The energy necessary is the same one century as another. Nor is there any marked fluctuation in the money cost of construction measured in a stable currency. The progressive economies resulting from improved manufacturing and transportation methods, and from substituting power and machinery for manual labor, are substantially offset by the higher wages paid the remaining manual labor. We are inclined to divide construction between materials and labor, the latter including only labor in the field. But the materials delivered are comprised almost wholly of labor, including mining and transporting the ore, building the railroad and cars on which it is transported, mining and transporting the fuel that smelts it, rolling or drawing the smelted iron and copper, fabricating it into machinery, loading and conveying it to the point of delivery.

Labor's Share in Profits Increases

For many generations the share of labor in the fruits of industry has been increasing, and it must continue to increase. The net result has been a slight upward trend in construction costs, and this must continue unless our civilization becomes static, or the labor-saving devices in the future prove more decisive than those of the past.

The popular impression that present construction costs are far in excess of pre-war costs is due to the fact that they are measured in new dollars worth only 60 to 70 per cent of the former dollars. And to this also is due the popular fallacy that property is enhanced in value, and especially that a utility is freely given a new and fictitious value, when all that happened was to translate one set of dollars into another set of the same aggregate intrinsic worth. It goes without saying that courts and commissions should have a sounder philosophy than that commonly prevailing among the public.

Error in "Prudent Investment" Theory

If it were possible to ascertain the original costs of a property constructed and installed under honest and efficient direction, and these costs were translated into present dollars, we should have the present "prudent investment" in that property; and that investment would be the same as the present reproduction cost new. But the popular application of the "prudent investment" method of valuation, which in some quarters it is proposed to use in a popular formula, involves the error noted in the preceding paragraph. The method of its

Digitized by Google

leading proponents is to try to find, for example, the number of dollars originally invested, say, in 1900 and add the number of 90-cent dollars invested in 1910, the number of 50-cent dollars in 1920 and the number of 65-cent dollars in 1930, along with all the intermediate systems of dollars, and call the numerical sum of these the present investment in dollars. This is not the only difficulty with the "prudent investment" method. The Interstate Commerce Commission reports show that in only a few of all the cases examined was it possible to find the original cost or "prudent investment" in any kind of money. If the Interstate Commerce Commission, with its extensive staff, cannot find these amounts there is little promise that the state commissions will be more successful. As might be expected from commission members who have given deep study to this special problem, only a few give countenance to the illogical application of the "prudent investment" theory.

As a practical matter the differences between "prudent investment" and "fair value" could be reconciled by a little clear thinking and precise expression. The investment is not cash; it is the physical property dedicated to the public use. We need not speculate as to how many dollars the bondholders, the stockholders, the contractors or others furnished the company to enable it to place the property in service. We need not make a doubtful attempt to find what premiums, commissions or discounts were paid to, or what losses were suffered by, the various people who made it possible to render this service. The only parties to the public contract are the company and the public, and what is used by the one party in serving the other is precisely the physical property. There is nothing speculative about that. Anyone can see it, and note its extent and condition.

The actual investment at any given time is resolved into the dollars of the time by taking an inventory of the physical property and pricing it for reproduction cost new, then deducting such depreciation, if any, as is proper in the circumstances. Always it is the property itself that is the investment, and the best place to look for it is not in the books of account but on the ground.

While "prudent investment" and reproduction cost new should be substantially the same amount, it does not follow that either can be assumed as the fair value. As a matter of law and good judgment, the "fair value" may be more or less than the investment, depending on the circumstances in each case. It is subject to determination by the courts and commissions, and not by others.

Province of the Court in Valuation

One of the most disturbing conditions in this country is the unfriendly attitude of the public toward valuation by the courts. Frequently a commission decision is reversed by the courts. If this happens in the federal instead of the state court the irritation is further increased.

But in general there is no appeal from the commission to the court except on a grave charge—that of confiscation. And unless confiscation is proved, the commission cannot be reversed. Where does the fault lie? With the court which performs an unpopular duty, or with the commission which has not been so careful? It is the prerogative of the commission to make the rate. In doing so it must find the value of the property. It is only on an authentic showing of confiscation that any court can assume jurisdiction.

The Supreme Court is the final interpreter of law in the United States, and in certain contingencies for the several states. Certain engineers and commissions and some of the courts are insistent in their request that the Supreme Court establish a formula for valuation, or at least apportion the weight that should be given to reproduction cost as compared with the other factors to be considered. The answer to this request may be found in the decree of the court delivered by Chief Justice Hughes, then an associate justice, on the Minnesota Rate Cases in 1912:

> The ascertainment of that value is not controlled by artificial rules. It is not a matter of formulas, but there must be a reasonable judgment having its basis in a proper consideration of all relevant facts.

We see no good reason why the court should be expected to reverse that principle, and little prospect of its further expansion or elucidation. In so intricate a problem as valuation the "reasonable judgment" of trained and competent arbitrators would seem a safer guide than an inert formula. A general principle expressed by a tribunal of such character as the Supreme Court should be applicable to conditions of the distant future as well as of the present, and through periods of either deflation or inflation.

Supreme Court Decisions Based on Smyth vs. Ames

The relevant facts to be considered were first set forth by the Supreme Court in Smyth vs. Ames, 169 U. S. Certain things were specifically listed but the need for including other elements was recognized as follows:

> In order to ascertain that value, the original cost of construction, the amount expended in permanent improvements, the amount and market value of its bonds and stock, the present as compared with the original cost of construction, the probable earning capacity of the property under particular rates prescribed by statute, and the sum required to pay operating expenses, are all matters for consideration, and are to be given such weight as may be just and right in each case. We do not say that there may not be other matters to be regarded in estimating the value of the property. What the company is entitled to ask is a fair return upon the value of that which it employs for the public convenience. On the other hand, what the public is entitled to demand is that no more be exacted from it than the services rendered it are reasonably worth.

Although Smyth vs. Ames is taken as the comprehensive basis for valuation methods which may have general application now and in the future, it is important to note that for present or immediate use it is specifically affected by more recent decisions.

The basic case, Smyth vs. Ames, was decided about 30 years ago. For the next fifteen years the cost of construction rose so slowly and so uniformly that the reproduction cost did not vary sharply from the original cost of property constructed within that period. A similar condition has existed for the past eight years. There may be longer periods in the future when original costs and reproduction costs will be virtually the same. And in the future also, under commission regulation, it may be feasible to ascertain original costs with a greater degree of accuracy than in the past. But if part of the property was constructed or installed before the war and other parts during or after the war there can be no direct comparison between original and present costs as expressed in the dollars of their respective times. Later decisions are consistent with Smyth vs. Ames.

As to the request for a formula, and for the weight

Digitized by Google

to be given present reproduction cost, the Supreme Court has clearly stated that there can be no formula, and that reproduction cost has controlling but not exclusive weight in the reasonable determination of the present fair value which must be taken as the rate base. There seems to be no need for any further rule. With the radical change in money values caused by the war, it does not appear how any reasonable interpretation of Smyth vs. Ames could arrive at a different conclusion.

The slow and laborious part of finding present value is taking the inventory. This work could be placed by the commission on the utility, where it belongs. The pricing of the inventory by the commission staff and the finding of fair value by the commission should involve but little time and expense. Where the inventory already has been taken, as in the case of the steam railroads, it is simpler to affix the present unit prices for the entire property, and thus obtain an approximate basis for present fair value, than to apply pre-war prices on part of it and various other prices on other parts, with a final result clearly out of harmony with the legal requirements of the situation.

It should be noted that while the legislative branch establishes rates it looks to the judicial branch for the rule of valuation on which those rates are based. Thus in the Transportation Act of 1920, supplementing the Interstate Commerce Act with nineteen paragraphs designated as Section 15a, paragraph 4 provides as follows: (1) it requires "due consideration to all the elements of value recognized by the law of the land for ratemaking purposes"; (b) warns against giving undue weight to the property investment account or original cost; and (c) finally directs that "the value so ascertained shall be deemed by the commission to be the value." It does not attempt to prevent review by asserting that the courts shall deem it to be the value.

Notwithstanding that the steam railroad inventories already in the files of the Interstate Commerce Commission could be quickly priced and extended to afford a basis from which to find the present fair value, the commission early in 1930 recommended to Congress a complete revision of Section 15a to obviate finding the value by the above method, and a bill has been introduced in the Senate for that purpose. The proposed revision contains a feature hardly less important than the process of valuation. It provides that such part of the excess earnings of the prosperous roads as under the present act may be applied by government to the aid of the weaker roads shall be used by the prosperous roads themselves for extensions, improvements and reduction of debt. This constitutes a rich concession to some of the Class I railroads. It may induce that group to reach a compromise with the commission which would preclude appeals to the Supreme Court. But for the other railroads and for public utilities in general it does not appear that the valuation laws as hitherto interpreted by the courts could be affected materially by the new method.

The proposed revision omits going concern value, an element almost universally recognized as part of the valuation for rate-making purposes. The decisions declare that it always exists but is hard to measure. To set it at zero is a genuine innovation. In the attempt to measure it, the first body rendering a decision has a certain advantage, as was strikingly expressed by that brilliant lawyer and tactician, the late Judge C. A. Prouty, in an argument before the Interstate Commerce Commission on Jan. 7, 1930, speaking as director of the valuation bureau:

> Going value might be even more difficult. How are you going to determine what shall be added? The fact that a thing is difficult does not excuse you from attempting to do it and you also enjoy this advantage, that if you will just simply *do* it, without undertaking to say precisely how you did it, nobody can ever find any fault with it. That will absolutely end it.

The advocates of the "prudent investment" theory assert that once the valuation is determined by that method it can easily be kept up to date by accountancy—showing the net property additions and deductions from time to time. That is probably true. It certainly is true while construction costs continue the even tenor of the last eight years. But this condition is not a function of "prudent investment." It is entirely independent, and prevails to the same degree if the valuation be by the present inventory method. In fact, it is all very easy and simple, except finding the first valuation in those cases where the rate-making bodies insist in effect that pre-war dollars and present dollars are the same.

Frequent Valuations Not Necessary

An outstanding misconception is the idea that under the "present fair value" method frequent valuations are necessary on account of the constant fluctuation in prices. As a matter of fact, the ordinary undulation up and down leaves the net value substantially unchanged unless or until a new plateau of costs is clearly established. Generally speaking, there are only three causes for a valuation. First, an improper rate in the beginning; second, a substantial change in net revenue from operation; and third, a cataclysm resulting in a radical change of currency. Valuations are not, and cannot be, so refined as to correct for lesser aberrations than these. "Prudent investment" would avail not.

John W. Burke

THIS STUDY and the one on depreciation to be published in a forthcoming issue are based on Mr. Burke's experience of about ten years in the valuation of utility and industrial properties, and that in turn on more than fifteen years experience on their construction.

Following graduation in the civil engineering course at Worcester Polytechnic Institute, Mr. Burke was engaged four years as an assistant engineer, and during the next ten years he was successively chief engineer on the design and construction of several properties including railroads, electric railways, dams, power plants, wharves, warehouses, municipal water supplies, sewers and pavements. He also had architectural experience.

For a number of years he was on the staff of large engineering organizations as a consulting engineer and superintendent of construction on public utility and industrial properties. He also examined and reported on numerous engineering projects and existing properties in this country and abroad, and prepared estimates of their costs and earnings. As president and general manager he operated an urban and interurban electric railway for six years.

Digitized by Google

In the older utilities the rates adopted at the beginning were sometimes haphazard for lack of experience. On this rather accidental method the 5-cent car fare was adopted. And it happened on the average to be fairly satisfactory until the World War reduced the old 5-cent fare to about 3 cents. But there were many special cases where power costs, length of haul, density of population, plan and topography of the city, varied widely from the average, and in some of these cases attempts to change the fare necessitated finding a valuation for the first time on the property in question.

Changes in net revenue result, of course, from variations in patronage and in costs of operation. These in large volume seldom occur suddenly, but throughout a series of years may become so substantial as to require redress.

The third cause—great changes in the value of money—occurs most infrequently. The world has witnessed only two major phenomena of this character in more than 100 years, those due to the wars of Napoleon and to the recent World War. The Civil War in this country was another event of the same kind, but not of world-wide influence. The belief is groundless, therefore, that changes in currency require frequent valuations, and that this could be obviated by the "prudent investment" method.

There are two other important influences on money values, but these operate so slowly as not to necessitate frequent valuations. First is the increase or decrease in gold supply. Second is the economy resulting from mass production. Thus the only sudden change in money value is due to a great war. Once that is settled an early displacement of values need not be expected. A valuation properly made after the currency has reached a new and fairly steady level, need not be remade in the near future.

The present fear of frequent valuations probably was induced by recent experience in abnormal times, when we witnessed in numerous cases two or more valuations of the same utility within ten years from the beginning of the war. The reason we have had more than one valuation from World War conditions is that we did not accurately discount these conditions. In 1918 it was generally estimated that post-war costs would stabilize at about 40 per cent above pre-war, whereas the increase has been double that, and in 1920 was even more. Despite the teachings of history, many of the courts and commissions refused to make adequate allowance for the new currency, and some of them cherished the delusion that pre-war costs were the eternal standard to which we must shortly return. Early official valuations based on these errors had to be corrected by subsequent ones.

Although a valuation properly made, after the currency is stabilized, can be kept approximately up to date for many years by accountancy under engineering direction, it should not continue indefinitely without a revaluation. Constant minor fluctuation in prices may in the course of years result in a substantial net change above or below those prevailing when the valuation was made, and there likewise may be an accumulative error in the new property accounts. Just as there is an ill-defined twilight zone between maintenance and depreciation, there often is a doubt as to the exact capital charge in retiring elements of property. The only accurate check is a revaluation, which automatically corrects the inventory, the change in costs, and the errors in accountancy judgments.

To arrive at "present fair value" under our law, depreciation must be considered. Although it seems illogical to deduct accrued depreciation from the fair cost of a public utility to find the rate base, the principle has been so well established by decisions that it must be accepted. In theory, a public utility property is dedicated to the service of the public. That property is the investment, which should be kept intact and uniform by maintenance and replacements, comprising part of the operating expenses paid by the public served. It seems inconsistent that any accumulation of these operating expenses should be deducted from the capital investment, and that thereby an amount be arbitrarily taken from the investor without any fault or omission on his part.

But as the courts direct that the utility valuation shall add for actual appreciation of the property, they require also that actual depreciation shall be deducted. Presumably this legal consistency is wise and prudent. It may be asserted that it has a further justification as applied to public utilities. It may be in the interest of a sound public policy that even a property that can collect no depreciation from its patrons be charged with a nominal amount of accrued depreciation as a spur to keep it in good operating condition; so that a property with deferred maintenance, from any cause, would not be allowed its full investment. It should be remembered that exact justice seldom can be had here below; substantial justice is all that may be expected.

It is positively stated by the Supreme Court in the United Railways & Electric Company of Baltimore vs. Harold E. West et al., Jan. 6, 1930, that depreciation, like the rate base, must be predicated on present value, and not on the so-called cost, meaning the cost expressed in dollars of the time of construction or installation. From the decision it is clear that depreciation is an operating expense. It should not be deducted from the rate base except for the special reasons hereinbefore stated. In any event, the depreciation fund is not intended to restore the property to newness. The Baltimore decision twice states that the purpose is "to maintain the level of efficiency for the public service."

Finally, the Supreme Court in the Baltimore case completes the logical requirements of equitable rate making by providing for some surplus earnings, which are necessary to maintain the financial credit of any industry, public or private, and which are dictated by sound business management.

Commission Regulation Practicable

It has been charged that regulation of public utilities by commission has failed. As well might we say that it has not been tried. From the recent report of the New York special legislative committee and from other evidence the public begins to realize that the problem of regulation is not merely one of good business judgement and legal knowledge, but is largely technical. This latter character has not been recognized sufficiently, and as a natural consequence only a small proportion of the commissioners were appointed for their technical training, and the commissions generally have not been clothed with the authority, or provided with the necessary funds, to procure an adequate engineering staff.

In many of the states it has been customary to select the commissioners from men prominent in public life. They are thus likely to possess tact, patience and knowledge of human nature, all indispensable qualifications, which, however, may be found in others who in addition

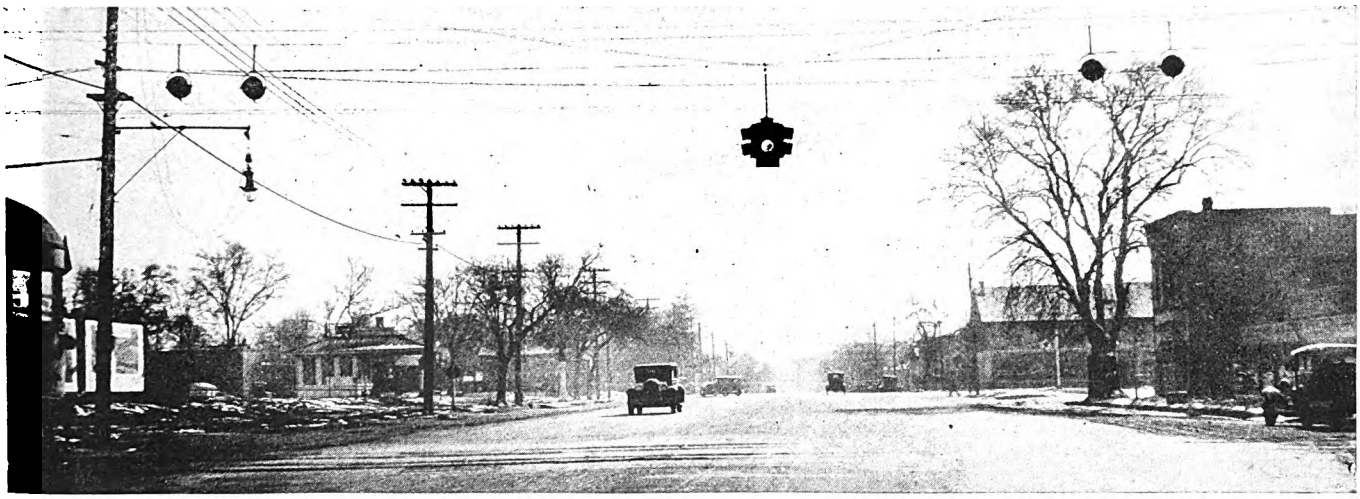
Digitized by Google

are equipped by special training to cope more effectively with questions of valuation and rate making. It would be a long step forward if the commission in its entirety had not only a good knowledge of law, but also of economics, of engineering and of finance; and if each of its members were proficient in three, or at least two, of these subjects. In an efficient regulatory body, quality also extends to the staff. It is small but select.

By far the most valuable work of a trained commission and staff would be to reassure the public. Prompt, open and clear decisions by a commission of eminent attainments would soon dispel all public doubt and suspicion. Another and hardly less important result would be that such a commission automatically would find itself in harmony with the law of the land on valuation. The dangerous discontent with many of the court decisions would cease when people discovered that there was no conflict between court and commission.

As might be expected, the Supreme Court, ever eminent in ability and experience, has developed and stated the clearest principles of valuation. These are in best accord with the views of experienced engineers and students of the subject. Of late we sometimes hear it suggested that the problem is economic rather than legal, and that therefore it is more reasonable to expect its proper solution by the commissions than by the courts. It is true that the commissions should conclude the matter and not leave it to the courts. But to accomplish this it will be necessary for some of the commissions to conform to sounder principles of valuation.

Combination Traffic and Warning Signal Used at Salt Lake City



Vehicular traffic is warned of the approach of an electric car by flashing lights in this signal installation at Salt Lake City

VEHICULAR traffic control and warning of the approach of electric interurban cars are dual functions of a novel signal installation made at Salt Lake City, Utah. The double track of the Bamberger Electric Railroad on Jennings Avenue crosses Second West Street at right angles. Because the latter street is 80 ft. wide between curbs, it was felt that a pipe standard at one side would be too much out of the line of vision. The municipal authorities would not permit the installation of a safety island in the middle of the street on which the flashing red projectors might be mounted on a pipe standard, as is usual in crossing signals. For this reason, four projectors were suspended between two messenger wires stretched across the street, one pair facing each direction. The units of a pair are 30 in. apart and are mounted adjustably on gimbal suspensions, so as to direct the concentrated beam most favorably upon the automobilist. These red projectors are 9⅝ in. in diameter with glass parabolic mirrors and 50-watt concentrated filament lamps. A traffic signal, of the four-way two-deck type with red and green lenses, is suspended above the center of the intersection, showing normally red to the railway and green to the traffic on Second West Street. Starting contactors are located above the track 400 ft. back of the intersection, with stopping contactors just on the far side of the street.

An electric train, approaching the crossing and passing under the starting contactor for that direction, throws the normally red traffic signal in the sight of the motorman to green, which indicates that the signal on Second West Street has been changed from green to red, stopping traffic on that street. At the same time, the red flashing projectors, which were hitherto dark, begin to flash alternately to indicate that a train is approaching the crossing. As soon as the trolley wheel of the electric car passes under the stopping contactor, beyond the crossing, the indications are thrown back to normal.

The lights and flasher relay are fed from a 110-volt alternating-current circuit, while the latch relays are operated from the 750-volt direct-current trolley. Separate relays are provided for each track, with their contacts in series for the red indication to the railway and in multiple for the green indication and the flashing lights. Thus a train quickly passing on one track will not stop the warning for a train approaching slowly on the other track.

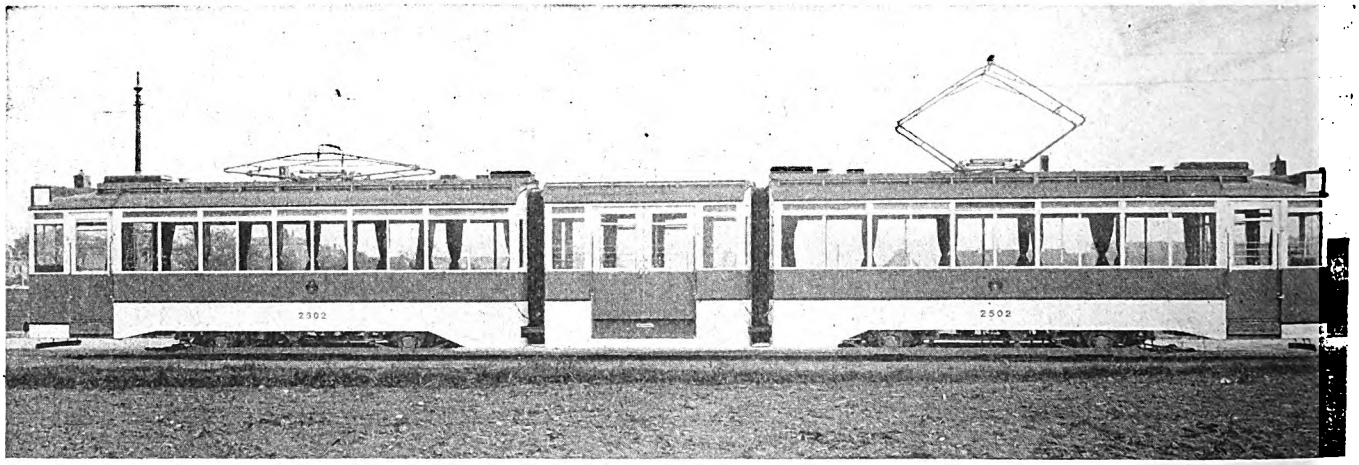
ARTICULATED CARS Teste

Two types of four-axle cars built in three sections, have been developed for street car service in this important German city. The methods used for supporting the bodies on four axles differ widely in the two designs, which were worked out in collaboration with the railway officials

GROWING street trailway traffic in Germany has caused a demand for large-capacity street cars, similar to those used extensively in American cities. This demand has led to the development by the management of the Dresden municipal railway system, in co-operation with two of the leading car builders, of two types of three-unit articulated trains which have a number of novel features.

One of the trains, built by the firm of Christoph & Unmack of Niesky, with electrical equipment by the Sachsenwerk of Niederseidlitz, comprises two single-truck car bodies with a third suspended between them by an articulated coupling. Each of the end sections has a seating capacity of 30 persons and standing room for six more. The central section has room for 30 standees and each end platform for 8 standees. The capacity is 60 seated and 58 standing passengers, a total of 118.

Extensions of the center sills of the middle section rest in articulating bearings in the end sections, which



The articulated car made by the Christoph & Unmack firm has two motor sections supporting a center section

Dresden

are carried on springs. The horizontal pull is taken on a coupling bolt which is carried in a swiveling bronze bushing. Vertical forces are transmitted through spring-supported roller bearings running on rails in the end section so as to damp out oscillations.

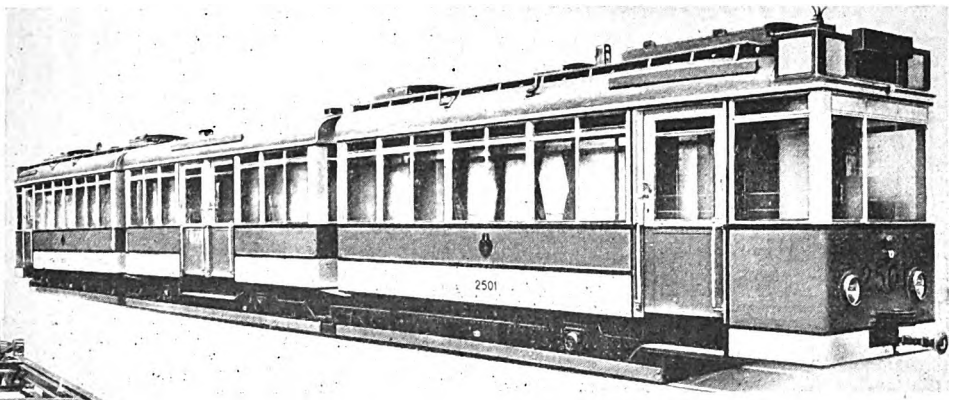
The end units are of the two-axle type without trucks, built, in general, according to standard German practice. Each wheel is supported by a leaf spring, each end of which is carried in a shackle with a spiral spring, making a three-point suspension and said to give very smooth running.

The underframing is built up of steel sections, joined with gusset plates and struts. The side frame is built according to a patented design known as the Niesky hollow-post construction. The posts are made of U-sections with reinforced flanges, while the carlines and connecting members are pressed steel. The sheet steel siding is formed into pockets for receiving the connecting bellows at the abutting ends of the bodies. The arch-type roof is covered with waterproof duck.

The double entrance doors are sliding, running in ball bearing tracks, and are geared to open simultaneously. The passageways between the sections are made of overlapping steel plates, and the bellows inclosing the sides are of leather covered with duck.

There are three independent braking systems on the car. The service brake is of the dynamic type, in which the car motors are short-circuited through suitable resistance. There is a hand brake of the toggle type acting on all axles. The new feature is a magnetic rail brake of the Jores type. To improve the braking action on slippery rail there is a sander which can be operated by hand from the motorman's position or automatically. The electromagnetic control of the sanders opens the release valve when there is an emergency application of the short-circuit brake or any application of the magnetic rail brake, which is intended for emergency stops only.

Four propulsion motors are used, one on each axle.



The articulated car furnished by the Waggon & Maschinenbau is of similar appearance to the other, although the construction differs radically

Development of controller made by the Sachsenwerk for one of the Dresden cars. The notching drums cause fingers to be depressed, closing the appropriate circuits

Each motor has a one-hour rating of 33 kw. at 550 volts d.c. and 800 r.p.m. Although the wheel diameter is only 650 mm. (25½ in.) the over-all height of the motors was kept small enough to give satisfactory road clearance and clearance between the motor and the car floor.

Since the train consists of three separate sections, and is arranged for double-end operation, it was necessary to carry the power and control wires from one end to the other. They are placed in cable ducts in the roof, terminating in connection boards at the ends of the units. Connections are made with extra flexible cable jumpers between the end and center sections.

Platform control for the motors was specified. On account of there being four relatively large motors grouped in two units, and as it was desired to be able to control each of the motor sections by itself, double-drum controllers were installed. The controllers have two interlocked drums rotating together, each drum handling the pair of motors in one section. Separate starting and braking resistances are installed for the two groups of motors. In order to make the controller approximately as easy to operate as a standard series-parallel controller, a notching type drum was adopted, in which the connections are not made directly by the pressure of the fingers on the segments, but in which the movement of the fingers opens or closes contacts pivoted to them. The one controller can handle either the two motor car sections together or one alone.

The dynamic brake for normal service is controlled by the same controller as the power. The brake circuits for the two pairs of motors are also independent, so that if one motor fails, half of the dynamic braking effort is obtained. Each magnet exerts a pull of 4,500 kg. (9,921 lb.).

Emergency braking is done with four rail shoes, with electromagnets of the Jores type. These brakes are attracted to the rails and are fed with line current. The brake controller is alongside the main controller, although not interlocked with it. The switches are so arranged that the magnets on the rear section are set first, obviating surges from having the rear section of the car strike the forward ones. When the track brakes are operating, a bell fed with line current continues ringing, so as to warn the operator not to keep the brake on longer than necessary.

Other equipment of the car is standard. The starting and braking resistors are mounted on the roof, and current is supplied through Fischer-type pantographs.

Construction of the other articulated car differs considerably from that described. It was built by the Waggon & Maschinenbau A. G. of Görlitz, and the elec-

trical equipment was furnished by the Siemens-Schuckert Werke of Berlin. In this car the center section is mounted on a four-axle truck, and the end sections are mounted on two-axle trucks, the inner ends of which rest on extensions of the middle truck, being joined with articulating couplings. The three sections are of approximately equal length, with double sliding doors in the center section. Each end section has seats for 21 passengers and standing room for three in the body, as well as eleven standing places on the end platform. The middle section has seats for twenty and standing room for 27, making altogether 62 seats and standing room for 55, or a total of 117 passengers.

The electrical equipment of this car consists of four motors of 38 kw. one-hour rating at 850 r.p.m. The control is similar to that of the other car, including dynamic braking for service and a magnetic rail brake for emergencies.

Principal dimensions of the two cars are given in the accompanying table.

Selection of Motor Controls

Depends on Circumstances

By R. S. BEERS
Transportation Engineering Department
General Electric Company, Erie, Pa.

WHEN selecting a type of control, an intimate knowledge of the work to be done, the scope of the control and the limitations of the operator, physical and otherwise, are essential. For instance, on a bus that must be steered, a control that is actuated by hand is not as desirable as one that is actuated by the foot. On the other hand, if there are few stops and little traffic, a hand control is simple and may be very successful.

One of the first considerations of controls is whether it be automatic or non-automatic. With the former the operator's work is reduced to the minimum, and the most of the control functions are predetermined, fixed and unchangeable; with non-automatic control success depends largely on skillful and intelligent manipulation.

Non-automatic control should preferably be used where the train weights vary through a wide range, such as with an electric locomotive which must run by itself as a unit and also when coupled to a heavy train. Automatic control is preferable where a number of similar units make up a train, as for motor equipments on subway, elevated and suburban electric trains.

With single cars in city streets, both types of control are successful. The majority are the simple non-automatic K type drum control. Trolley bus controls abroad are generally non-automatic, while in this country both automatic and non-automatic are in successful use. The selection of automatic control for trolley buses was made largely to relieve the operator of as much mental and physical labor as possible. Incident to this, on trolley buses, the foot is preferable to the hand for operation of the controller. This, in turn, leads to the automatic type which requires only pressing a lever to obtain smooth acceleration. The non-automatic type requires a pause on each controller notch, which is not as easily done with the foot as with the hand because the feet are not trained for such nicety of action.

Success of automatic controls depends on a governing influence, the one commonly used being a combination of motor current and time. A system control governed by current alone, if arranged for a level road, would probably make the acceleration too slow on a hill; or, if arranged for the hill, it would be too fast and jerky on the level. Likewise, if time alone is used, there is no limit to the abuse that the motors may receive. Fortunately, a combination of the two is a successful arrangement. Modern transportation vehicles, with accelerating rates as high as passenger comfort will permit, require a control that normally accelerates on time but is prevented from exceeding a safe motor current value. So long as the acceleration rate can not be tampered with by the operator, one is sure of always starting the vehicle at a high rate, which in frequent stop service is one of the essentials necessary to maintain a high schedule speed. Today we talk high accelerating rates, 3 m.p.h.p.s. being the value most frequently used, while formerly it was 1.5 m.p.h.p.s. Actually, our motormen on city cars with K controllers have been increasing the accelerating rates to maintain their running time. A survey covering the United States brought out that the average time for turning a K controller "full on" was seven seconds, but, in a number of cities, it is done in four and five seconds. Translated into average accelerating rates, this gives values of 2 to 2.5 m.p.h.p.s. When the average accelerating rate exceeds 2.5 m.p.h.p.s., it is necessary to have more notches than are included in the usual K controller in order to obtain smooth and comfortable acceleration. It is obvious that the more notches used, the smaller the current changes will be when each section of resistance is cut out. This has a twofold value, as it insures comfortable acceleration and, at the same time, reduces the likelihood of wheel slippage.

The best control for fast acceleration is automatic in action. So long as the acceleration rate is high and constant, this insures the quickest getaway. Where the acceleration rate is selected by the operator, there is no valid reason why a simpler, non-automatic control with sufficient controller notches should not be used.

The modern fast acceleration control is compact and easily installed under the car or in a cabinet inside the car or bus. Controls of this type are in successful use on either cars or buses in large cities like Chicago, Baltimore, and Brooklyn, as well as others such as Albany, New Orleans, Salt Lake City, Youngstown and Knoxville.

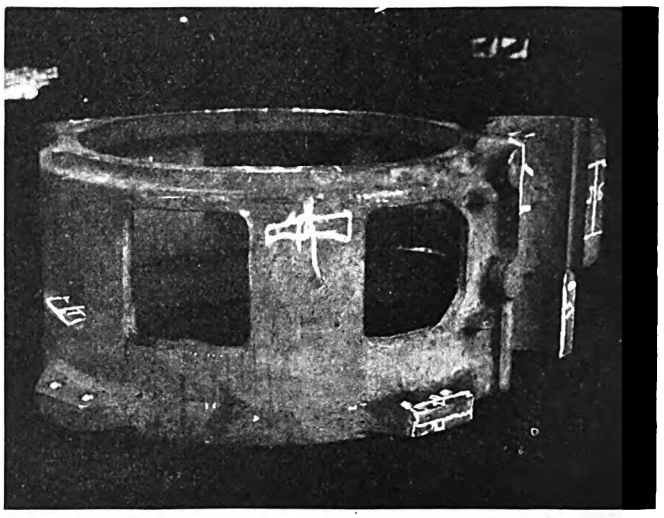
Aluminum Frame

Reduces Railway Motor Weight

MORE than a year ago the Westinghouse Electric & Manufacturing Company inaugurated plans for reducing the weights of heavy electric railway motors, particularly single-phase motors. It was realized that, where possible, use of light-weight materials would make a considerable saving in weight if substituted for steel or iron. As a result of conferences with the engineers of the Aluminum Company of America, it was estimated that savings of 600 to 1,000 lb. would be possible on a 200-hp. single-phase motor of the type commonly used on the Pennsylvania Railroad; New York, New Haven & Hartford; New York, Westchester & Boston; the Reading Railroad, and similar installations. This was found possible because the motor shell in single-phase machines is not a part of the magnetic circuit. Beside the frame, it was found possible to make end housings and axle caps of aluminum. Similar parts have been in use on an experimental car of the Cleveland Railway for some three years.

In order to make a satisfactory motor shell, it was necessary to develop an aluminum alloy casting which in strength would compare favorably with the cast-steel frame now generally in use. The first frame was cast in aluminum alloy from a pattern made for cast steel. The motor case of aluminum alloy weighed 553 lb. as compared to 1,295 lb. for the steel casting from the same pattern. It was, however, necessary to test the aluminum frame under conditions approximating those of actual service. Accordingly, the Aluminum Company set up the castings on an improvised car axle, with the motor nose centered as in service and dropped weights from various heights on to the middle of the shell. The steel frame was tested first with a 1,000 lb. weight dropped 2 ft., 3 ft., 4 ft., 5 ft., 6 ft. and 7 ft., with no resulting indications of failure. The first aluminum frame failed when the 1,000-lb. weight was dropped 4 ft., by breaking out of the nose from the main frame. With the information thus determined at hand, the frame was redesigned, certain parts being increased in cross-section and others diminished. The new frame which was cast withstood the 1,000-lb. weight dropped from heights up to 7 ft.

Not satisfied with this performance, the test was continued, a 2,000-lb. weight being dropped on the steel frame up to a height of 7 ft. at intervals of 1 ft., with no disturbance of the steel structure being evident. The second aluminum casting was then subjected to the 2,000-lb. weight and could not be fractured by it when dropped up to the 7-ft. height. It was not considered necessary to carry the test further, as the stresses existing in the frame when the 2,000-lb. weight was dropped 7 ft. were greater than could possibly be encountered in service. Furthermore, it was considered that other parts of the motor, its mounting, the parts of the truck to which the stresses must necessarily be diverted, were considerably weaker than the frame. The Westinghouse engineers considered the aluminum frame to be entirely suitable for railway service. Plans are now under way for the introduction of test equipment of the aluminum-equipped single-phase railway motors, to obtain actual service runs.



Frame for single-phase railway motor of cast aluminum alloy, which weighs only 40 per cent as much as the steel casting it replaces

By the redesign of the castings, in connection with the new alloy used for its manufacture, the weight was reduced to 533 lb. as compared with the steel castings of 1,295 lb., or a net saving per frame of 762 lb. This reduction in weight should prove a material factor in the design of future single-phase motors. It is understood that the Westinghouse Company is prepared to offer these motors with aluminum frames, end housings, axle caps, spiders, and similar castings. Direct-current motors, in which the frame is part of the magnetic circuit, are being built with aluminum end housings, axle caps and similar parts. Since the substitution means a considerable reduction in unsprung weight, it is believed the change should be attractive.

P.L.M. Gets Heavy Locomotives

NEW electric locomotives placed in service on the French Paris-Lyons-Mediterranean railway a few months ago and operating between Chambery and St.-Jean-de-Maurienne, near the Italian border, have demonstrated a remarkable hauling capacity, according to a report to the Department of Commerce by Trade Commissioner Louis Hall, at Paris.

Over comparatively heavy grades these locomotives can haul trains of 600 tons at a speed of approximately 55 m.p.h., while along other parts of the line trains of more than 800 tons have attained speeds of from 60 to 66 m.p.h. These electric locomotives are said to be twice as powerful as the most powerful steam locomotives of the "Mountain" type operated over the P.L.M.

In the Viau substation the two 12-phase, 1,500-kw. rectifiers convert power from 60-cycle alternating current to 600-volt direct current

Montreal Tramways Installs Third

Automatic Rectifier Substation

Following the successful use of mercury arc rectifiers with full automatic control for more than three years, the Montreal system continues the expansion of its power supply with similar equipment, but with many distinctive features

By

M. L. de ANGELIS
Assistant Electrical Engineer
Montreal Tramways, Montreal, Canada

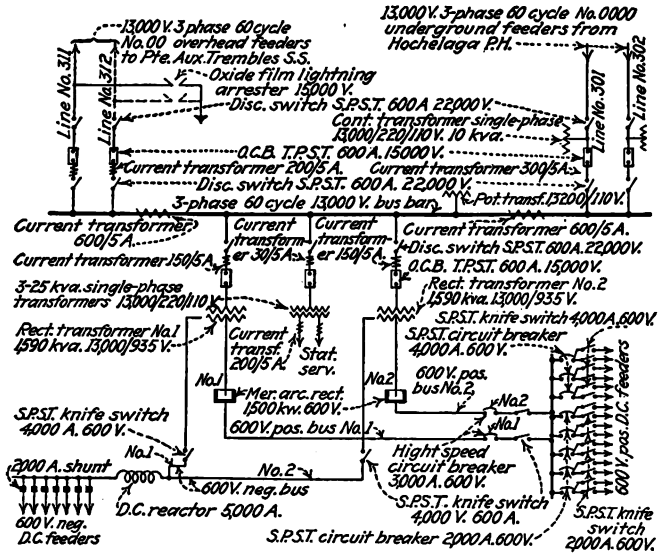
SINCE the first installation of mercury arc rectifiers was made by the Montreal Tramways in the Verdun substation in February, 1927, the results have been followed with great interest by the management. This installation, which formed the subject of an article in ELECTRIC RAILWAY JOURNAL for April 30, 1927, was followed the succeeding January by a second rectifier station at Rockfield (see the JOURNAL for August, 1929). These installations have been so successful from the points of view of reliability maintenance and operating costs that the company decided to extend the use of this type of converting apparatus and to install it in the new Viau substation. This third station began operation on April 10 of this year.

Construction of this station was necessary to take care of increased traffic in the eastern districts and to replace another one the equipment of which had become inadequate and somewhat inefficient. Moreover, due to the change in the load center of the sections fed by the old station, the latter was no longer correctly situated for minimum direct-current distribution losses. It was, therefore, decided to locate the new station further east, where several important converging lines have track loops.

In the main the building is similar to that of the Rockfield Station, the approximate over-all dimensions being 52 ft. 6 in. by 36 ft. 1 in. by 32 ft. high, the volumetric density being 20.2 cu.ft. per kilowatt. It is of brick with a concrete basement carefully waterproofed. The building is entirely fireproof. The roof is of Aerocrete slabs covered with Celotex mastic cement 1 in. thick. The high-tension oil circuit breaker and busbar cells are of concrete and situated along one side of the main room, while the rectifiers are on the other side.

The control switchboard room is on the same level as the rectifier room, without any separating wall between, as shown in the plan. This layout has given the advantage of using one side of the control room for the

Digitized by Google



One-line schematic diagram showing the circuits of the Viau rectifier substation of the Montreal Tramways

high-tension cells, reducing to a minimum the total length of the building. The bake-out transformer is between the two rectifier tanks on a small foundation against the longitudinal wall. All the high-tension compartments are provided with removable asbestos doors.

The rectifiers rest on the floor without any special foundation, and the floor of the transformer compartments is laid directly on the ground.

No lifting device has been installed above the rectifiers for maintenance purposes, because the heaviest part requiring inspection is the anode, which, with its clamping plate, can be lifted by two men without difficulty.

The basement contains a main room, a d.c. switchboard room, two small rooms for the incoming and outgoing high-tension feeders, a furnace room and a toilet. In the main room are the two fan-and-water-cooler sets, the three circulating water pumps, the water storage tank, the negative series reactor, the bake-out resistor, the control batteries, the transformer bank for station service and the negative feeder cable potheads and shunts. In the d.c. switchboard room are the rectifier and positive feeder panels, the high-speed circuit breakers, the shunt filters for attenuation of telephone interference and, in general, all the main d.c. conductors.

The transformer cells are at the side of the building nearest the rectifiers and are separated from the interior by a fireproof wall. They are roofed over but have a large front opening with Kinnear rolling steel doors and heavy wire screens. These doors permit easy removal of the transformers and provide air for cooling them. Louvers in the outside wall above the doors evacuate the hot air. In the roof of each cell a hook has been installed just above the transformer for lifting the core and windings by means of a chain block.

Ventilation of the basement and main floor rooms is obtained by means of two openings in the basement walls, equipped with horizontal shutters and screens. The hot air is discharged through two Robertson ventilators in the roof. The outlets of the fans for the water coolers converge to a vertical flue built into the wall between the two transformer cells. Solenoid-operated gates prevent the exhaust air backing into either of the two fans which may not be operating.

The electrical equipment, which was supplied by the Canadian General Electric Company. includes:

Two 1,500-kw., 12-phase, 600-volt steel tank mercury arc rectifiers with alternating-current ignition capable of carrying 150 per cent full rated load for two hours.

Two 13,000/935-volt, 60-cycle, delta/quadruple zigzag 3/12-phase transformers for the rectifiers and capable of the same overload as the latter.

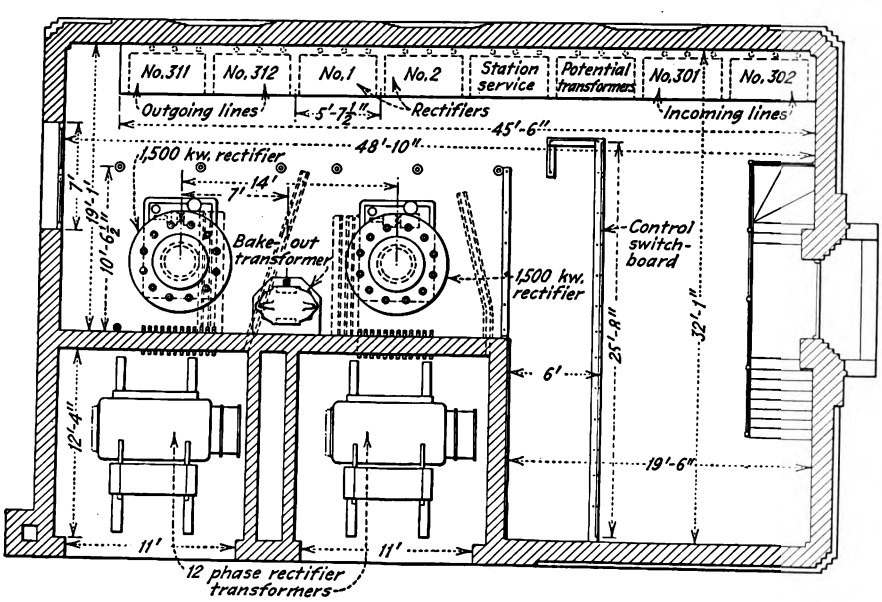
One 5,000-amp. series reactor rated to withstand 150 per cent load for two hours.

One bake-out transformer and resistors.

Two self-cooling systems for the circulating water required for cooling the rectifiers.

One complete automatic switching equipment for the operation of the following circuits:

Two incoming high-tension lines.
Two outgoing high-tension lines.
Two 1,500-kw. mercury arc rectifier units.
One station service transformer bank.
Three 4,000-amp. d.c. automatic reclosing feeders.
Five 2,000-amp d.c. automatic reclosing feeders.
One synchronous selector supervisory control equipment, and necessary storage batteries.



As in the previous rectifier substations in Montreal, the main apparatus and switchboard are on one floor, with the transformers in separate compartments

The outstanding novel features of the main apparatus are:

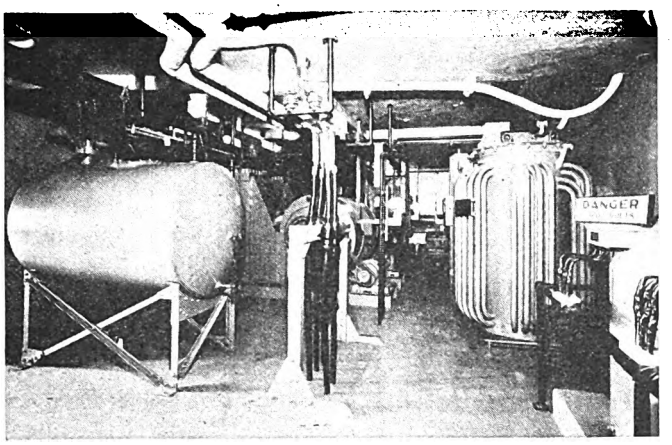
The mercury arc rectifiers, while generally similar to those in the earlier stations, have a number of different features. The tank proper with its associated devices is mounted on an insulated metal base with vacuum pumps, gages, water valves and other devices. The anodes are of graphite and are insulated from the tank by a special "micalex" insulator, which acts also as a vacuum seal. It has high mechanical strength, and its expansion coefficient is similar to that of the steel rod forming the terminal to the anode.

Anti-backfiring devices are mounted in the anode shields. Automatically controlled anode and tank heaters keep the rectifier at proper temperature under all weather conditions.

Each unit has its own water-cooling system, consisting of a blower,

Digitized by Google

radiator and pump for circulating the water. A water storage tank common to the two rectifiers supplies the make-up water should the city water fail for a long period. A third or spare pump is so arranged with valves that it may be used to replace either of the other two pumps. The fans operate only when the water has reached a temperature necessitating forced ventilation.



Auxiliary equipment, including water tanks and blowers and house transformers, are mounted compactly in the basement

The Langmuir mercury condensation pump is of the two-stage type, allowing the very low pressure to be obtained quickly in the rectifier tank. The cooling water for this pump is taken from the self-cooling system of the rectifier.

The approximate weight of the rectifier, together with accessories, is 8,000 lb.

Transformers for the rectifiers are of the outdoor, self-cooled type, with oil conservator. The three primary terminals are brought through horizontal bushings mounted on the vertical wall of the tank and located in an oil-filled junction box fixed to the tank. This box is provided with an oilproof stuffing box designed to receive the high-tension 3-phase cable feeding the transformer. The primary is connected in delta and the secondary in quadruple zigzag with the interphase transformers mounted in the main transformer tank. The complete transformers weigh 33,300 lb.

A bake-out transformer with adjustable load resistor is supplied for "forming" the rectifier tank after it may have been opened for a prolonged period. This method has proved to be simple and quick.

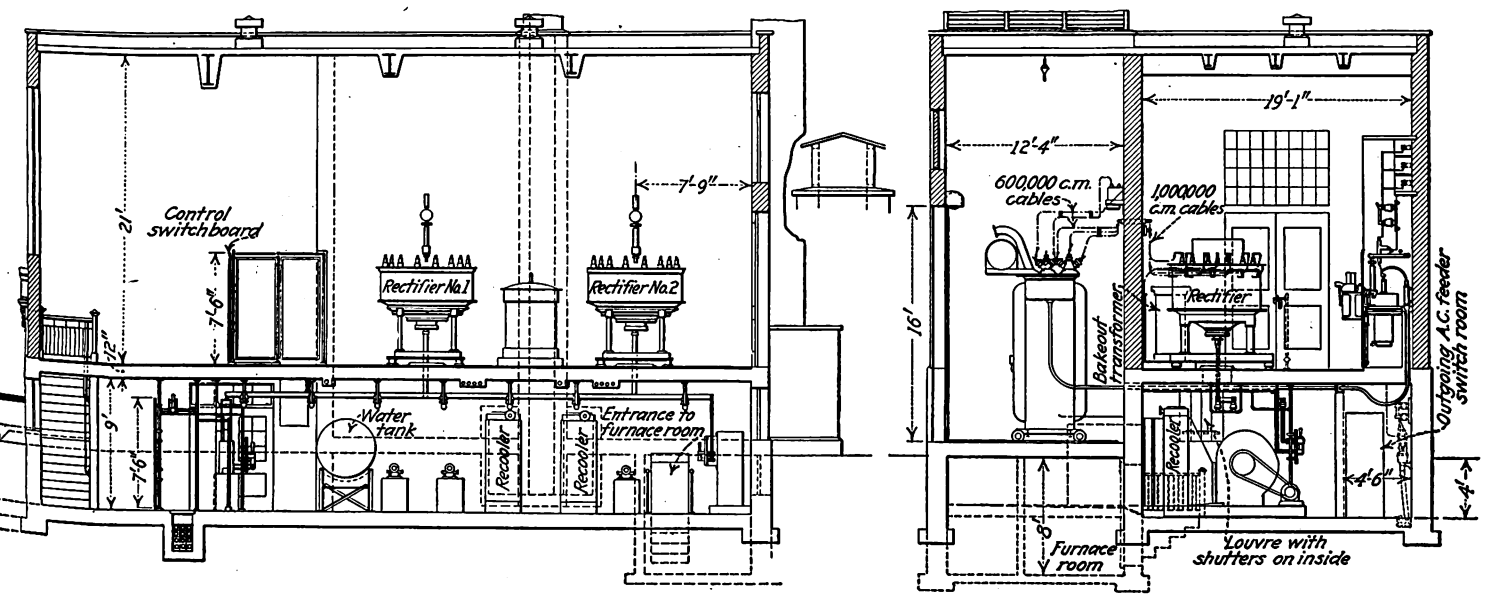
The automatic switching equipment of this station can function: (a) Completely automatically on load responsive impulse; (b) by supervisory control from the load dispatcher's office, or (c) manually from the switchboard in the substation. If operating automatically, the starting indication is given when the d.c. trolley voltage falls below a predetermined value, provided, however, that the high-tension supply has proper phase and voltage conditions. The sequence consists, as in all mercury arc rectifier installations, in establishing the excitation arcs, closing the high-tension breaker to supply a.c. voltage to the main anode and connecting the rectifier to the d.c. bus through a polarized high-speed breaker.

The second unit is started when the load on the first has reached a predetermined value for a definite time. Should the leading unit fail to start within a certain delay, the trailing unit is set in operation and replaces entirely the leading one. The trailing unit shuts down when the load on the station decreases sufficiently to be carried by one unit only, and the leading rectifier is stopped when the load has fallen below a suitable value, provided, however, that the d.c. bus voltage be above a certain amount.

The eight d.c. feeder breakers are self-reclosing and open on a given steady overload or on short circuit. They reclose on stub or multiple feed within a definite time if the load is not excessive.

The usual protective features for satisfactory rectifier operation are included in the automatic control. A throw-over switch has been included to cut out the automatic starting devices and, at the same time, to establish the excitation arcs. A pull-button switch allows the closing and opening of the high-tension rectifier breaker, and another similar switch controls the d.c. breaker. The a.c. over-current protection is retained under manual operation, and the vacuum regulation can also be operated manually, but the tank and anode heaters are always controlled automatically.

When the throw-over switch mentioned above is set for manual operation, the load dispatcher control is entirely cut out of service so as to eliminate all possibility of faulty and dangerous switching from the part of the dispatcher. He, nevertheless, receives proper indication



By the plan adopted this 3,000-kw. rectifier substation is held to small over-all dimensions without sacrifice of accessibility

Digitized by Google

the substation apparatus will be under the control of the load dispatcher located at Cote Street substation in the center of the downtown district of Montreal and adjacent to the company's head office.

The equipment is of the synchronous selector type and allows the dispatcher to perform the following operations at Viau substation:

1. Open and close—Two high-tension incoming line oil circuit breakers, two high-tension outgoing line oil circuit breakers, and one high-tension oil circuit breaker feeding the station service transformer bank.
2. Start, stop and release to automatic operation, the two mercury arc rectifier units.
3. Open and release to automatic operation, the eight d.c. feeder breakers.

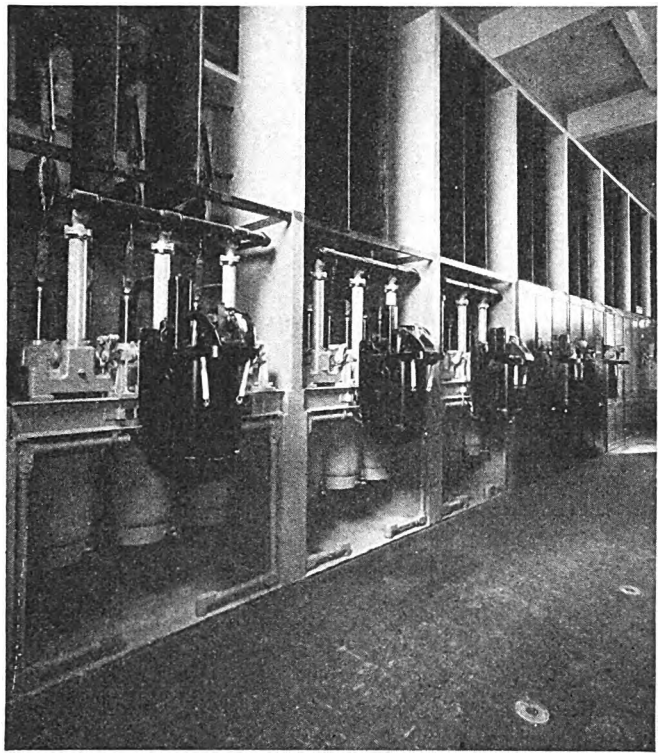
At the dispatcher's office several indications will be obtained, namely:

1. Indication for the open and closed position of two high-tension incoming line oil circuit breakers, two high-tension outgoing line oil circuit breakers, one high-tension oil circuit breaker feeding the station service transformer, and eight direct-current feeder breakers.
2. Indication for the running, stopped and automatic position of the control equipment for the two mercury arc rectifier units.

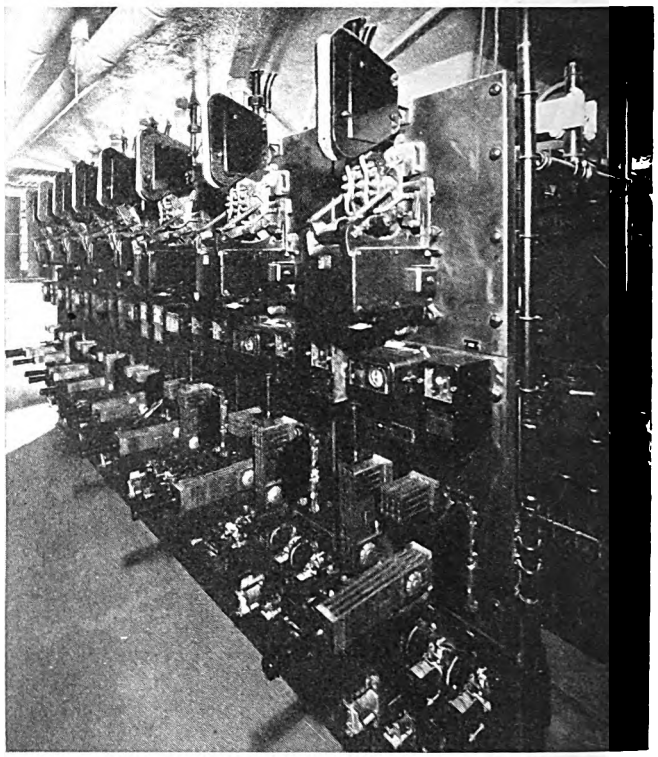
The equipment at the load dispatcher's office consists of the control keys, indicating lamps, polarized relays and synchronous selectors for sending the control impulses and indicating the positions of the various supervised units.

The equipment at Viau substation consists of the supervisory devices, which transmit the control impulses from the dispatcher to the auxiliary control relays and send back indication impulses to the dispatcher. The panels are wired for 22 controls and indications, although only seventeen are actually used at present. Each supervised unit has, at the dispatcher's office, a key and lamp combination comprising a two-position control key, a red and green indicating lamp and a white lamp which signals an automatic operation of the corresponding supervised unit. Each combination has a two-position push-and-pull selecting key to stop the selectors at a point corresponding to the unit it is desired to control and an associated amber lamp to indicate when the selectors are connected to that particular unit. An alarm bell warns the dispatcher whenever the equipment has operated for any cause whatsoever. Exide storage batteries of 120 volts are installed, one at the substation and one at the dispatcher's station. They are of small ampere-hour capacity and obtain a trickle charge from Tungar rectifiers.

This supervisory system requires only four line wires between stations, but to provide for future developments telemetering, telephone and wire break-downs, a six-pair rubber insulated, lead-covering cable has been installed in the same underground duct line as the high-tension feeders.



High-tension breakers are mounted in individual cells with fireproof partitions



A close view of the direct-current feeder board in the Viau substation

It may be mentioned that a polarized high-speed circuit breaker has been installed between each rectifier and the positive bus and set to open in the reverse current direction. This breaker, by opening the circuit in less than 0.01 second, positively prevents damage to the anodes in the occurrence of a back fire, no matter of what material the anodes are built.

One unit was started on April 10 and the other on April 29 of this year. Since then the operation has been satisfactory and without any back fire. The station has delivered 1,131,500 kw.-hr. and been continuously in service, the two units having been in operation during 1,572 hours out of a total of 1,968 hours of elapsed time. One rectifier (unit No. 2) has been available for service throughout this period, while the other was, soon after it had been started, out of service for a few days, due to development of a leak in one of the high vacuum pipes which had been damaged during erection. However, this was easily and quickly repaired and the unit has been available ever since.

Cleveland Railway Has Contributory Pension Plan

Costs are shared by the company and its employees, and the risk is carried by two long-established insurance companies. Other pension plans summarized

CONTRARY to the customary practice of electric railway companies in providing old age pensions, the Cleveland arrangement is on a contributory basis and the risk is carried by two long-established life insurance companies. The company aids liberally in the support of the plan, and acts as intermediary in the collection of the monthly dues. This plan has been in effect since July, 1927. Prior to the adoption of the plan a complete analysis of accrued and impending liabilities was made by competent actuarial authorities.

Membership in the plan is voluntary, contingent upon at least six months of continuous service with the company, but approximately 95 per cent of the company's employees have availed themselves of its privileges. In applying for membership the employee simply fills out an application consenting to be bound by the regulations of the plan, and authorizes monthly deductions from his salary. The employees are divided into five classifications, based upon the rate of pay received annually, and dues are fixed in accordance with the following schedule:

Class	Annual Basic Rate of Salary or Pay	Amount of Monthly Dues
A	$1,500 or less	$1.50
B	1,501 to 2,100	2.50
C	2,101 to 2,700	3.50
D	2,701 to 4,500	4.50
E	4,501 and over	6.00

As the plan represents a co-operative effort between the members and the Cleveland Railway, provision has been made for joint representation on the committees which handle the details of administration. There is, first of all, a general committee of 34 members, representing the six major departments of the company. Each department is subdivided according to operating units or classes of employment, and each such unit annually chooses a member to represent it on the general committee. To be eligible for election as general committeeman an employee must have been continuously in the company's service for at least one year. Each of the departmental branches of the general committee selects a chairman, who serves as a representative of that department on the advisory committee. The advisory committee consists of these six chairmen, supplemented by six members appointed by the president of the company, the appointed members including the vice-president and general manager, the superintendent of personnel, the auditor, and the chief surgeon. From the membership of the advisory committee there is elected a chairman and a secretary of the committee. The advisory committee supervises the general work of the plan and determines questions of policy relating thereto.

Membership in the plan carries with it life insurance benefits under a group insurance policy, issued by the Travelers Insurance Company, the amount of which is based upon the member's period of continuous service. Beginning at $750 for those with service records of from six months to one year, the amount increases to $1,000 after the first year, after which it is increased $100 per year until the maximum of $2,000 is attained after eleven years of service. Membership also carries with it a supplemental $500 insurance policy which had been carried by the company at its own expense for several years before the present plan was adopted. Upon leaving the employ of the company the members are entitled to continue their policies in force with the Travelers Insurance Company without medical examination, at rates applicable to the member's then attained age and class of risk.

Should death occur through accidental cause, additional amounts of insurance are paid in accordance with a group policy carried with the Metropolitan Life Insurance Company, the amount for Class A members being $1,500, and for Class B, C, D and E members, $2,000. Under this latter policy, compensation varying from one-half to the entire amount is paid for certain specified injuries, such as loss of sight, loss of limb, etc., the provisions in general corresponding with those in the standard commercial accident insurance policy.

Under another arrangement with the Metropolitan Life Insurance Company, weekly benefits for loss of time due to sickness or accident are paid to the amount of $12.50 for class A members and $20 for classes B, C, D and E. These benefits continue for thirteen weeks and are supplemented in the cases of Classes B. C, D and E by weekly "occupational accident benefits" as provided under the Ohio state compensation law.

Retirement benefits, payable monthly for life, become available to members at age 65, if then in the company's service, after at least 25 years of continuous service. By mutual consent of the railway and the members of the plan, a member may be retired prior to the normal retirement date with a modified monthly benefit. Members who have reached the retirement age if they so desire and the company approves may continue at their regular occupations. Provision has also been made whereby the member at age 60 may receive a smaller retirement benefit, varying with the age of his wife, which benefit will be paid to his wife throughout her lifetime, should she survive him. Satisfactory evidence of good health is required of a member who desires to exercise this option.

Disability retirement benefits shall also become payable to members who may become totally and permanently disabled after at least twenty years of continuous service, regardless of age. These disability retirement benefits begin following the maximum payments of weekly sick and accident benefits and any total and permanent disability benefits which may have been paid under the group life policy.

The amount of the monthly retirement benefits is determined according to the number of years of service in each salary class. Monthly payments to members in

Digitized by Google

the various classes, following 25 years of service are as follows: Class A, $30; class B, $50; class C, $70; class D, $90, and class E, $120. This rate increases slightly with each year of continuous service to the members credit at the period of retirement, reaching a maximum in the case of a member who has 59 years of service. Forty years of service, for instance, provides monthly payments in the various classes as follows: Class A, $48; class B, $80; class C, $112; class D, $144, and class E, $175.

In establishing the salary classification for members with long records of service with the company at the time the plan was set up, the salary under which the member was employed on July 1, 1927, was used as a basis for determining the amount of his retirement and other benefits. If an employee changes from one salary classification to another, the retirement benefit will be the total of the benefit in one class, multiplied by the number of years in that class, plus the benefit of the other class multiplied by the number of years in that class, etc.

Upon leaving the service of the Cleveland Railway members have the privilege of exercising any one of three options with the Metropolitan Life Insurance Company in adjusting their retirement benefits. There is a cash surrender value amounting to from 21 per cent to 69 per cent of the total contributions made to the fund, a paid-up retirement benefit, requiring no further deposits and payable for life beginning at the normal retirement date, or there is the privilege of continuing to buy retirement benefits on the individual's own account at the then prevailing rate for such a service. In the event of death while in the service of the company the member's beneficiary receives the cash surrender value under the retirement benefit in addition to all benefits payable under the group life or accidental death clauses.

All members living in the Greater Cleveland area are entitled under the plan to avail themselves, when sick or injured, of the visiting nurse service provided by the Metropolitan Life Insurance Company. The nurse will, upon call, make at least one visit on every case, and will return as often as necessary upon instructions of the member's physician. Members are urged to communicate immediately with the nursing service with the view of minimizing the effects of any illness or injury.

Other Pension Plans

The pension plan of the Lehigh Valley Transit Company, Allentown, Pa., is conducted much along the lines of certain other companies, the details of whose plans were set forth in the August, 1930, issue of this paper. It has been in effect since July, 1913, and embraces all employees of the company. The pension paid is a flat sum of $20 per month, and is available after from 20 to 25 years of continuous service. No age requirement is specified. The expense of the plan is carried entirely by the company out of current earnings, and no reserve has been set up.

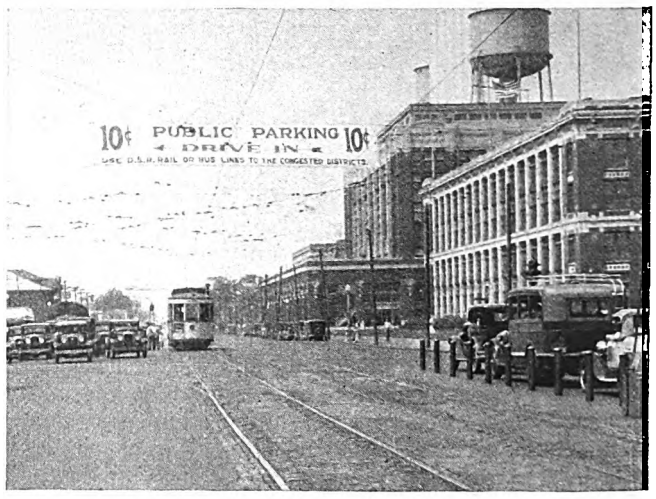
The company has never had an analysis made of its pension liabilities and costs and, with an increasing number of employees going on the pension list, is becoming apprehensive as to the future. The management, according to H. F. Dicke, vice-president, thinks that a pension plan is highly commendable, but is of the opinion that the employees should contribute to its support and that the company should take steps to accrue a necessary reserve.

Since November, 1901, the United Electric Railways of Providence, R. I., has had an old age pension plan in effect on its property. Open to all employees, it is available at age 70, without service requirements. The amount of the pension is based upon the average weekly pay for the last ten years prior to retirement. Payments are made out of current funds without the assistance of contributions from the employees themselves. No reserve has been accumulated. As the result of an analysis of its pension liabilities, the company anticipates difficulties in the future and has under consideration a revision of its present plan in order to reduce its cost, which is at present averaging approximately 1 per cent of the company's total receipts.

Under the proposed plan employees reaching the age of 70 who have served the company for 25 years would receive a pension of $40 per month, with an addition of $1 per month for each year of service over 25 years. In order to take care of special cases it is proposed that the company may, at its discretion, retire with pension any employee who has reached the age of 65 years and who has been with the company twenty years. The pension in such cases would be $35 per month, plus $1 for each year of service over twenty years.

D.S.R. Parking Service Popular

AUTOMOBILE parking service was instituted some time ago by the Department of Street Railways, Detroit, Mich., in conjunction with its street car and bus terminal on Woodward Avenue, 5½ miles from the center of the city. The parking lot is situated about 150 ft. from Woodward Avenue, in the rear of the terminal arcade, which obscures it from the view of the



Banner across Woodward Avenue advertises automobile parking service of the Department of Street Railways, Detroit, Mich.

passing motorists. With the inauguration of this service, the department circulated handbills to persons driving in that vicinity, and the patronage gradually increased to a point where there were approximately 175 cars parked in the lot daily. Recently this patronage has been further stimulated by the erection of a streamer across Woodward Avenue, indicating the location of the lot, and featuring the exceptionally low rate of 10 cents for all-day parking. The first day that the banner was erected there was an increase of 75 cars in the lot, and there is every indication that the full parking capacity of approximately 300 cars will soon be reached.

A spacious and well-lighted shop encourages good workmanship

Surrounding Men With

CONVENIENCES

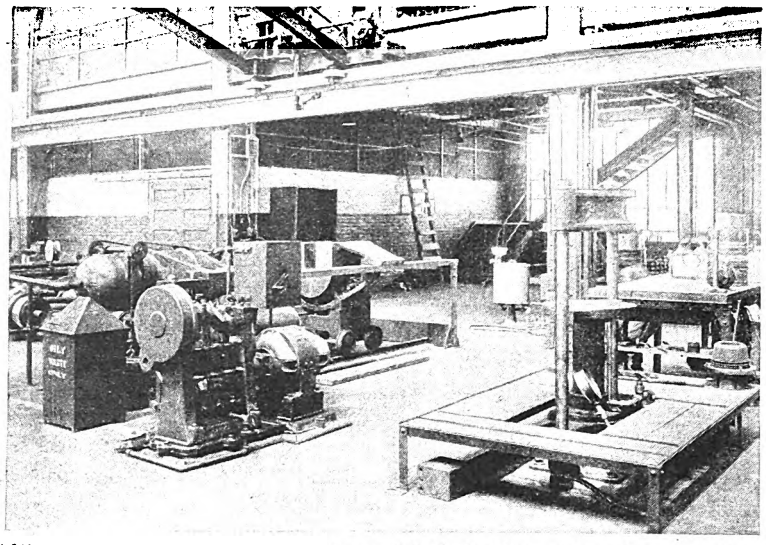
By H. W. McCARTY
Master Mechanic Capital Traction Company
Washington, D. C.

Labor is today the most important element in maintenance work and it is vital that all possible steps be taken to promote its efficiency

OF ALL the items entering into the maintenance of electric railway equipment, no single item represents so large a part of the cost as labor. It is, therefore, highly important and necessary, in order to get the maximum efficiency out of labor, that men be surrounded with those conveniences and comforts that will in a large meausre cause a voluntary response to the demands of modern efficiencey. In some instances, the charge is made that modern day labor is not as efficient, is not as responsive to the ever-increasing demands for economy and high standards of maintenance as it was in the past. This may or may not be true, but the fact remains that the average production or maintenance plant has not kept pace in meeting the rapidly changing conditions, in so far as they apply to the needs of the human element, by surrounding men with those conveniences and comforts that will promote the greatest degree of satisfaction and contentment. An agreeable surrounding elevates the morale, creates an enthusiastic cooperation and has a most definite and direct bearing on the character of the work performed.

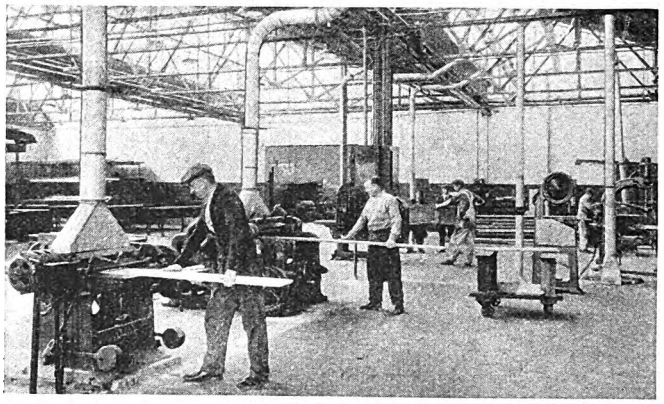
Equipment men are more alive than ever to the fact that higher standards of maintenance and inspection will improve performance, and this not only results in reducing ultimate maintenance, but has the far greater effect of improving public relations by the prevention of equip-

Digitized by Google



Individual motor drive eliminates unsightly belting and makes the shop a better place in which to work

ment failures in service. With this thought in mind, no effort should be spared in seeing that men who are engaged in the important work of maintenance are supplied with the proper tools to do that work, and that they are provided with those comforts and conveniences that will bring a real interest in their work.

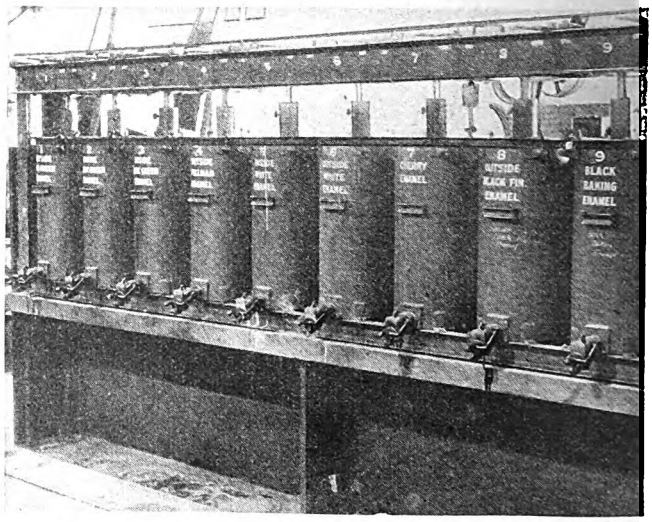


Suction waste removal system promotes cleanliness and protects health of employees

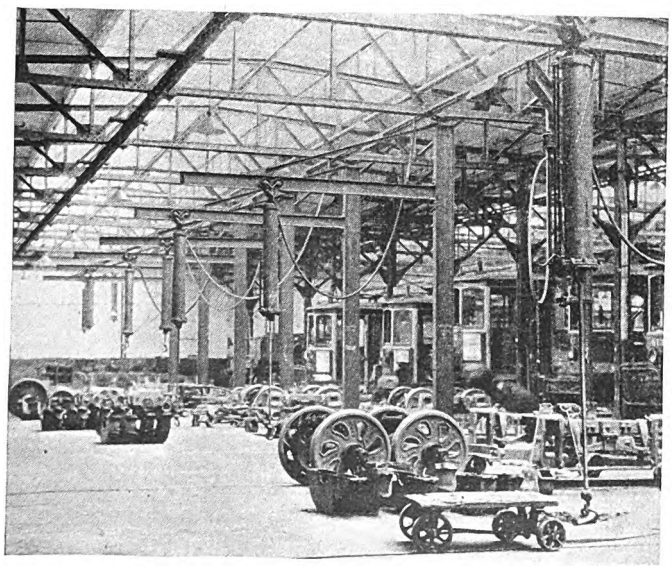
Shop methods, processes and tools used in the upkeep and maintenance of equipment become obsolete in time. There is a wide field for study in regard to the improvement of the machinery used in many of the shop plants. We cannot hope to modernize the human element without modernizing the mechanical element as well. Therefore, we should not expect the same high standard of workmanship from the man who is not given modern tools with which to do his work as we do from the man who is supplied with such tools and appliances. By the same token, we cannot expect to maintain the same high morale in an organization of men who are not surrounded with modern conveniences in the form of ideal shop layouts, as in those organizations which have provided for the welfare and comfort of the employee. Much is said and written about the modernization of equipment and operation, but too little stress seems to have been laid upon the need for the modernization of the conditions affecting the human element, which, after all, is largely responsible for the efficient manner in which equipment may be maintained and operated.

Owen D. Young has very truly said: "Time and brawn alone are not factors by which the barometer of productivity can be forecast: the problem today is to deal with the limits within which men can work with zest and spirit and pride of accomplishment. When zest departs, labor becomes drudgery; when exhaustion enters, labor becomes slavery."

Modern tools help a man to feel that the organization of which he is a part, is an up-to-date organization, and the fact that he is given modern appliances with which to work is an incentive for him to demonstrate his ability to turn out more and better work. Men will not reflect that contentment and satisfaction with their jobs if physical effort is largely depended upon to perform labors and duties that should be lightened by the use of modern appliances. Conferences for the training of foremen



Convenient storage of paints is an important factor in shop cleanliness



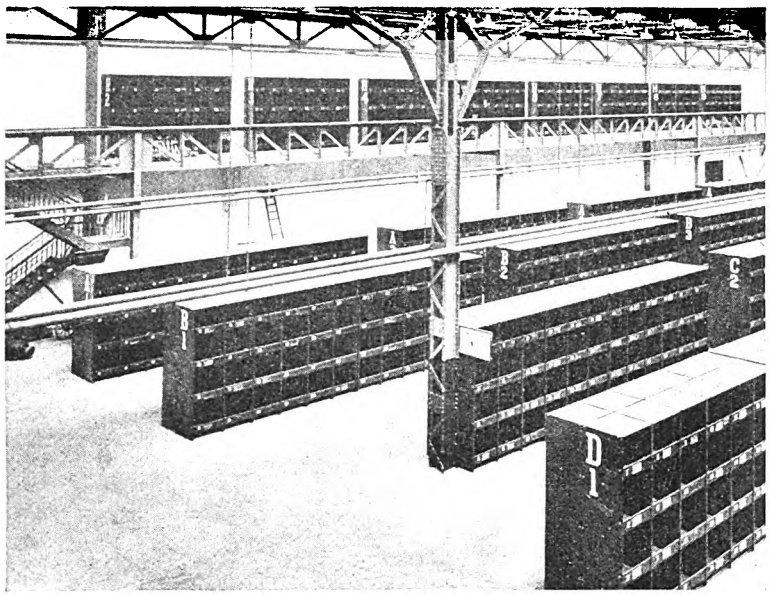
Numerous and convenient hoists save much time and labor

Digitized by Google

and workmen have come much to the fore in recent years, and they have accomplished much toward inspiring men with a higher conception of their jobs. How much more enthusiasm could be aroused in the individual, if, coupled with this training, he is supplied with the proper tools with which to carry out any ideas he may have acquired through these conferences in the matter of increased efficiency or improved methods of operation.

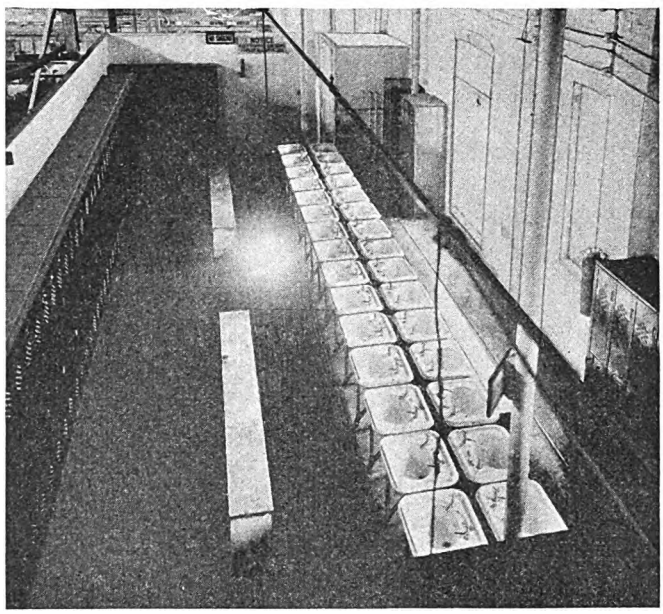
It is rather a sad reflection that, in the past development of the street railway industry, too little attention was given to the study of labor conditions, with the result that on many properties men are required to perform the work of maintenance in surroundings and with tools that thoroughly discourage the creation of a lively interest on the part of the men.

Shops should be laid out and arranged so as to provide proper light, ventilation, and sanitation. The cost of these and many other conveniences that can be supplied to the workman will be more than justified by the



Adequate storeroom facilities contribute greatly to the efficiency of the shop

First-aid cabinet and bulletin board remind employees of the importance of safety



Lockers and washing facilities are an important part of the shop equipment

increased mental and physical effort exerted in his work, and the building-up of an invaluable morale in the organization. Work, under conditions and surroundings that are pleasant and comfortable, no matter how hard, does not produce that feeling of fatigue and restlessness that accompanies labor performed under conditions that are far from ideal. A contented employee is an asset, for contentment breeds good will. These attributes, in turn, are contagious, and are forerunners of a spirit of co-operation, that, if fostered, will go a long way in any organization toward solving the problem of successful and economical operation.

No company can render the best type of service unless it has a well-trained and enthusiastic group of employees. This condition is particularly true of the electric railways; everything possible might be done in the way of improving equipment and service, but maximum results can never be obtained without the wholehearted co-operation of the men, of whom some are in the somewhat peculiar position of having to sell the product which they manufacture.

More Route Changes in Brooklyn

NEW surface car routings of the Brooklyn & Queens Transit Corporation in the vicinity of the Manhattan Bridge and Brooklyn Bridge plazas were made effective on Aug. 25, contributing to traffic relief at the bridge approaches and allowing an improvement of street car service. These changes follow an extensive rerouting in the Borough Hall section, completed on April 6.

Demonstration school of Cleveland Railway where linemen familiarize themselves with details of overhead construction

Instruction School for Linemen

Since the establishment of training facilities the Cleveland Railway has decreased the number of trolley wire breaks and reduced expenditures for overhead materials and supplies

By Angus Scott
Assistant Superintendent of Overhead Lines, Cleveland, Ohio

REALIZING that the secret of efficient line construction and maintenance lies solely in the knowledge possessed by the workmen of their daily tasks, the line division of the Cleveland Railway has developed a method of training its employees which has proved effective. If workmen can be told how to do a certain job, and also see the act performed on a model at the same time, they are far better able to fully understand the problem than if they are merely told how to do the work. With this point in mind, a small scale model of actual overhead construction has been erected in the basement of line division headquarters for the instruction of the linemen. As may be seen in the accompanying illustration, the wire is erected at a height comparable to working conditions on the towers of the line trucks and involves all the elements of a line—poles, feeder cables, span wires, frogs and crossings.

With this construction before them, the foremen and linemen are made familiar with the standard construction as shown in their standard books, and anything not clear in the book is instantly made clear through the model. How to locate switch frogs accurately, the proper method of making various ties, the location of breaks or grounds in telephone circuits, and innumerable other items can be discussed and performed by the men under supervision. Any new device or method of doing a job more quickly or efficiently can be tried out and demonstrated to the men.

Construction which is not standard, and that which embodies the use of excessive fittings, is also erected. Foremen, or those in charge of line trucks, are examined as to the details of this construction. They are then shown how a saving in both labor and materials may be effected by eliminating excess parts which would have to be periodically renewed, and by properly installing fittings so as to secure the maximum life. Correct construction is thoroughly explained to the men, with the end in view of having them understand the actual savings in dollars and cents which is brought about by obtaining the maximum life of fittings with a minimum amount of wear on the contact wire.

The model overhead plant is especially valuable in the instruction of drivers and helpers in the proper methods of installing overhead fittings, how to use their tools and how to handle blocks and tackle on a tower truck. This may be accomplished by having the men work in a small area bounded by wooden horses fashioned into a square by means of short timbers, giving the effect of a tower

Digitized by Google

table. New men are allowed to practice on the model instead of attempting to practice while working on the line. This model line, especially, proved its worth when it was necessary to practically double our working force when engaged in a rapid transit construction program.

The system of line maintenance, which is based on car movements, is explained to the men, and the stages at which different fittings are to be regarded as worn out are shown by attaching to the model actual fittings which have been removed from the line. The necessity for accurate judgment can be stressed by showing the effect on the contact wire when fittings have been allowed to remain too long in the line at acceleration points or other bad spots.

Apparatus such as wire gages, dynamometers, micrometer gages, and the use of tension-temperature charts are explained and used on the model construction. The use of these instruments results in construction which can be economically gaged and controlled, but the men using them cannot merely follow the instructions concerning their use, but must also know the "why" and "how" concerning them or our plan of procedure will be defeated.

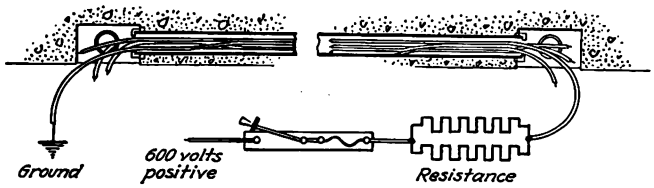
In the school, the physical characteristics of trolley wire are discussed with the men. Such facts as wire fatigue, breaking strength, expansion and contraction of wires with temperature variations are explained to them. Various samples of wire that have broken due to fatigue are shown, as are also samples of wire that should have been removed because of liability of breaking due to fatigue. In conjunction with the line school, a combined course in principles of foremanship and the elements of practical electricity is being conducted for the men.

That the school has fully justified the time and little investment put into it may be readily seen by the fact that all the major items of expense for line material such as ears, splicers, frogs and trolley wire, show considerable reductions from the previous year. A comparison of materials used during 1928 and 1929 shows a decrease of 3,020 ears during 1929. Inherent trolley breaks have also been decreased to a minimum.

Loosening Tight Wires in Conduit*

By R. S. McIntosh

Superintendent of Electrical Construction
Cleveland Railway



Heating tight wires in conduit, as done by the Cleveland Railway, softens insulation and makes removal easy

SOMETIMES wires laid in iron conduit, which after years of service have adhered tightly to the conduit walls, must be removed. The electrical maintenance division of the Cleveland Railway power department has devised a satisfactory method for loosening them when it is impossible to pull them out by ordinary means.

A bank of resistances with a capacity five to six times the current rating of the wire to be removed is placed in series with it through a fused switch, as shown in the diagram. The switch is then connected to the 600-volt line and the other end of the wire grounded. In a short time the heat developed in the wire so softens the insulation on it and on the other wires as well that they are pulled out easily. This method has been successful when wires were broken off so close to the pull boxes that no pulling was possible.

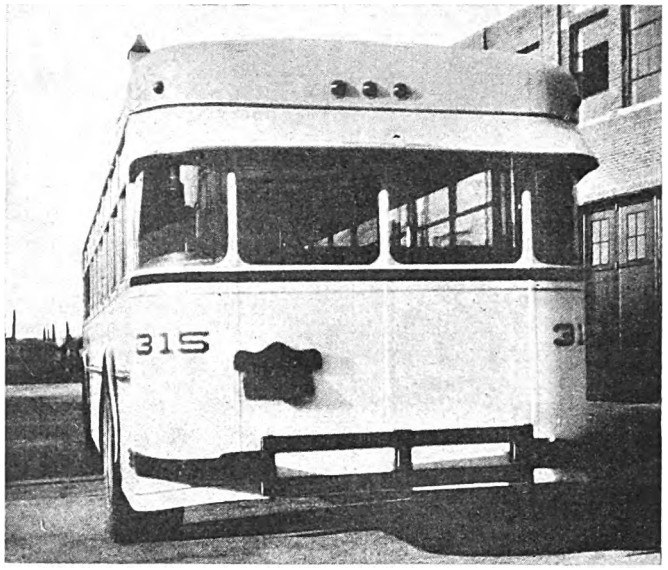
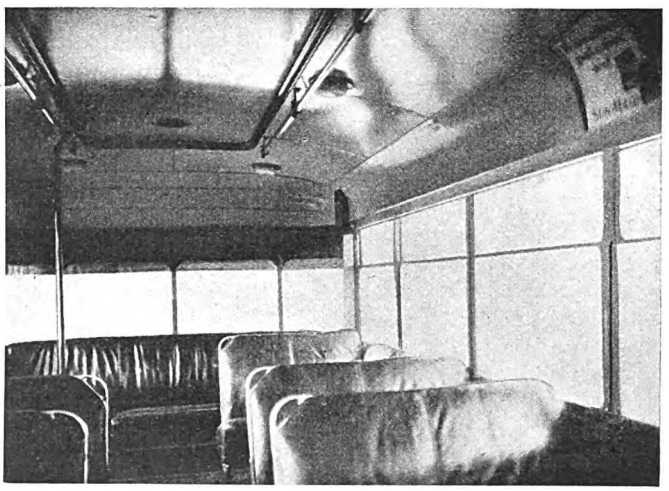
Exhaust Gas Fumes Discharged From Roof of Bus



Detroit D. S. R. bus equipped for roof discharge of exhaust fumes



An inconspicuous insulated casing carries the exhaust pipe up through the left rear corner of the bus

BY DISCHARGING the exhaust gases from the engines through the roof of the bus, the Department of Street Railways, Detroit, has been able to secure better ventilation and keep obnoxious fumes out of the interior and away from pedestrians as well. The gases are carried above the suction zone behind the vehicle so that they do not follow along with it.

The exhaust pipes from the two engines are joined at the left side of the bus into a single discharge pipe of square cross-section, and are carried upward to a point approximately 3 in. above the roof. Surrounding the exhaust pipe is a casing of 12-gage sheet steel, covered

Digitized by Google

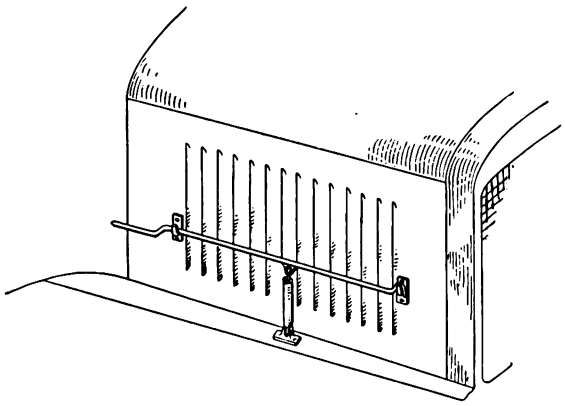
with a ¼-in. layer of molded fire-resisting material. This outer air space continues out to a point approximately 5 in. above the roof, ending in a flared cap. By this means a suction is created and cool air is drawn from within the bus into the air spaces around the exhaust pipe. This keeps the outer casing cool and eliminates any fire hazard or possibility of burning a passenger. Condensed vapors drain through a carbon-cleaning trap door with three ⅛-in. holes bored through it.

Road tests have shown that the exhaust gases are carried to a height sufficient to obviate inconvenience, and all objectionable noises have been eliminated. No added back pressure is evident.

Bus Hood Clamp Locks Easily*

By L. Rose
Cleveland Railway

IN ORDER to overcome the defects experienced with motor coach hood locks, a simple and inexpensive hood clamp has been developed by the Cleveland Railway. The hood locks were sometimes found difficult to latch, with the result that mechanics and operators developed a tendency to latch only those most conveniently located. It was also found that the hood locks were



Easily installed bar clamp reduces vibration and improves appearance

often unfastened by vibration. With either of these two conditions present, the hood would rattle or vibrate excessively.

The hood clamp consists of a single bar which is pivoted at the center to a heavy-duty standard, sleeve-type hood-clamp body. This is fastened by means of a clevis bracket, which is bolted to the hood sill or the front fender in the regular manner. Two brackets are mounted on each side of the motor bonnet, one toward the front and one toward the rear which support the clamping bars and, in this way, securely lock the motor bonnet. By mounting the sleeve body on the hood sill close to the bottom of the hood, sufficient wedging action is obtained to prevent lateral vibration of the bonnet sides.

The bar clamp has been a satisfactory substitute for the hood locks by eliminating unnecessary noise due to loose hood sides and by reducing hood wear. The manipulation of the clamp is so simple and easy that it removes any temptation for the mechanics and operators to leave the hood unlocked.

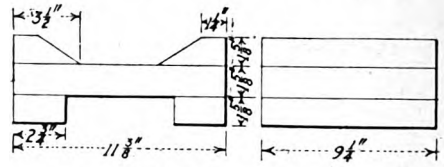
Simple Cradle for Storing Armatures

TO KEEP armatures off the floor and prevent the windings becoming damaged by coming in contact with metallic chips or some other foreign substance the Richmond Railways, Staten Island, N. Y., has built a special cradle. It is made of oak and occupies a floor space of 11⅜x9¼ in. A 1⅝-in. plank 11⅜ in. wide by 9¼ in.



Since this armature cradle has been in service at the shop of the Richmond Railways failures have been reduced

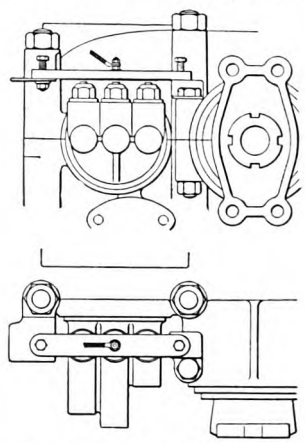
long is fastened to two rectangular blocks 2¾x9¼ in. Two tapered blocks bolted to the top of this plank directly over each foot provide a support for the armature and prevent rolling. These blocks are 1⅝ in. thick and 9¼ in. long. The bottom dimension is 3½ in. and the top 1¼ in., thereby providing a 2¼-in. taper.

Warning Signal Insures Proper Meshing of Gears*

By E. von Pirch

Hamburger Hochbahn Aktiengesellschaft
Hamburg, Germany

WEAR of transmission change gears on buses of the Hamburger Hochbahn Aktiengesellschaft was at times considerable. This was, to a great extent, due to the neglect of the operators to throw in the gear shift lever fully when changing speeds. As a result, the gear teeth did not mesh their full width, and were soon stripped by the excessive strain imposed upon them.



An electric circuit is completed through gear rods when gears are not fully meshed lighting a red lamp on the dash

To correct this fault, a red lamp is placed on the dashboard and made to light whenever the gears did not mesh fully. This is accomplished by placing the gear rods in the circuit with the lamp by a simple electrical contact at the arresting pin. With the gears fully in mesh, the lamp is shunted, but when the gears are not fully in mesh the circuit is completed through the lamp. The device has not only reduced failures, but has lessened the time for overhauling gears in the shop and the number of buses out of service.

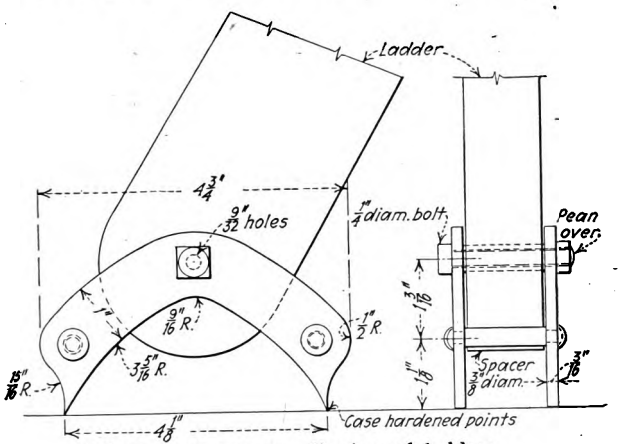
Steel Plate Safety Shoes Fitted to Ladders*

By Terance Scullin
Superintendent of Equipment and Buildings (Retired)
Cleveland Railway

LADDERS are prevented from slipping by a device designed and put into effective use at the Harvard Shops of the Cleveland Railway. By means of sharply pointed safety shoes, the foot of the ladder obtains a firm bearing against both vertical and horizontal forces.



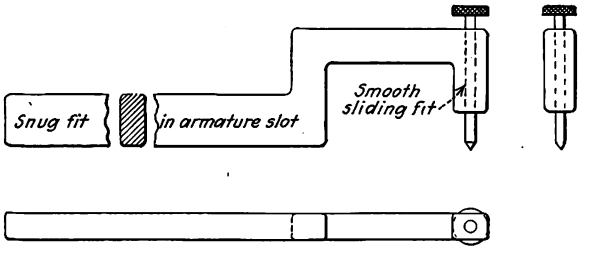
Safety shoes prevent slipping of ladders

The safety shoes consist of four U-shaped plates, two for each ladder leg, and are made of $\frac{3}{16}$-in. steel plate. The arms of the U's are brought to a point and hardened in order to increase their resistance to splitting or cracking. They are mounted at the end of the ladder leg on a toggle consisting of a $\frac{1}{4}$-in. bolt and a length of standard $\frac{1}{8}$-in. pipe. Two spacers made of $\frac{3}{8}$-in. steel rod keep the plates equidistant.

Gage to Check Alignment of Commutators

By J. S. Dean
Renewal Parts Engineering Department
Westinghouse Electric & Manufacturing Company

ONE of the essential factors for good commutation is the correct alignment of the commutator bar or mica with respect to the armature slot of the core. Depending upon the design of the armature windings of



Steel gage to check alignment of armature core slots with respect to commutator bar or mica

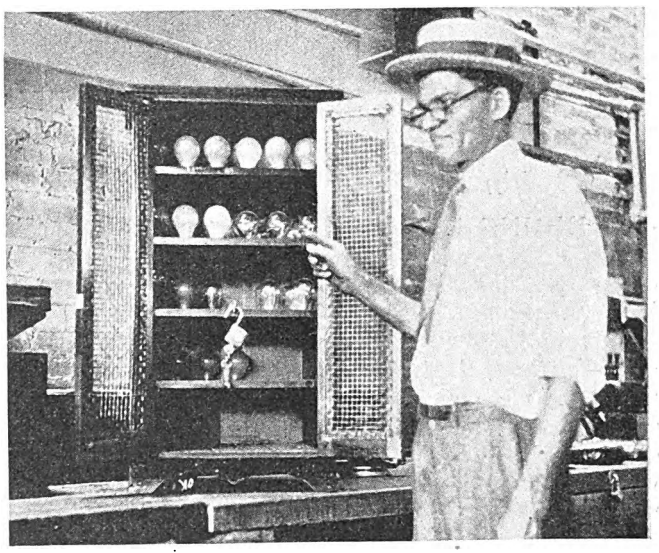
railway motors, the slots in the core should line up with either the commutator mica or the center line of the bar. For the various types of motors, this information should be obtained from the armature winding diagrams.

When refilling a worn-out commutator on a railway armature core with a new set of assembled segments, or replacing a new commutator, it is common practice to check its alignment by means of a piece of string held along the center line of the tooth or the slot of the core. This method of checking the assembly is more or less unreliable, as it depends entirely upon the accuracy of the workman's eye. A simple tool, designed as shown in an accompanying illustration, eliminates all doubt in connection with this work and provides a means to get the correct alignment of the commutator bar or mica with respect to the armature core slot. It is possible, for certain types of machines, to simplify this tool, by making the center point a part of the main body of the tool, which would eliminate the knurl headed sliding pin. Such a tool can readily be made at a very moderate cost and should prove to be a good investment for better maintenance.

Storage of Lamps During Car Overhaul*

By C. B. Hall
Chief Clerk Mechanical Department
Virginia Electric & Power Company, Norfolk, Va.

FOR the storage of electric bulbs during car overhauling periods, a convenient portable cabinet has been made in the shops of the Virginia Electric & Power Company at Norfolk, Va. The previous practice of allowing lamps to remain in their sockets while the car underwent an overhaul caused considerable breakage.



Handy cabinet used for the housing of lamps during the period of car overhaul

The plan of removing all lamp bulbs when cars are shopped has now been adopted, and the cabinet has been made for the special purpose of housing the lamps handily, pending their reinstallation in the cars on leaving the repair shops. The cabinet measures 16x19½x36 in., with five shelves having 1⅛-in. drilled holes to accommodate 150 lamps. A regular lamp socket with a non-threaded collar is placed on one side of the cabinet for a quick push-in test of each lamp prior to placing it on one of the shelves.

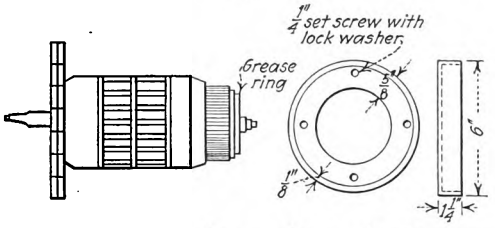
Grease Ring Protects Commutators on Ball-Bearing Motors*

By H. J. Beadle
Equipment Engineer
Dallas Railway & Terminal Company

GREASE and oil are very easily spattered upon the commutator and brush-holders of railway armatures of the ball-bearing type, especially during hot weather. To protect these parts, the Dallas Railway &



Brass cast ring fitted to ring nut keeps oil off commutator **and brush-holders** of ball-bearing armatures

Terminal Company has recently equipped the armatures of its traction motors with light-weight grease rings.

These grease rings are cast from brass and are attached to the armature ring nut which holds the commutator in position. They are held securely to the ring nut by four set screws with lock washers, lightly soldered to the ring nut.

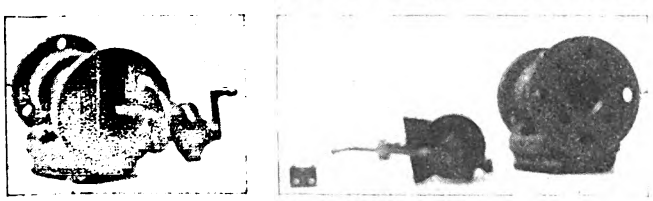
Since the installation of this device, the commutators and brush-holders have been free from grease and oil.

Slide Valve Grinder*

By C. W. Wood
Master Mechanic
Virginia Public Service Company
Hampton, Va.

GRINDING in of slide valves of type D relays is facilitated by a device developed in the shops of the Virginia Public Service Company, Hampton, Va. It replaces the tiresome method of hand grinding in which the mechanic used a rod 8 in. long with a ½-in. crossbar soldered across the rod about ½ in. from one end. The crossbar was placed in the air port of the slide valve, and moved back and forth by hand until the valve was seated.

The new device consists of a pair of automobile



Valve grinding facilitated with a device equipped with **speedometer** reduction gears

speedometer reduction gears, equipped with a handle and a flywheel to which a connecting rod and eccentric pin are attached. The eccentric pin is ⅜ in. off center, giving the connecting rod a stroke of ¾ in. A crossbar, ⅛x⅛x½ in. is fitted to the connecting rod in such a manner that it is held securely in the port of the valve by the weight of the connecting rod.

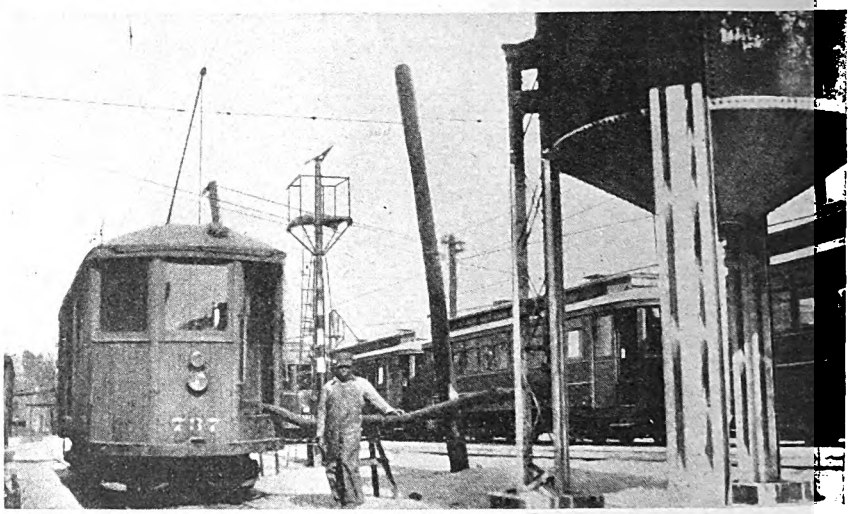
The grinder is bolted to one of the bracket bolt holes at the face of the relay casting by means of an angle bracket fitted with a stud. Pressure is applied through the bronze spring of the slide valve. To remove the valve from the port, it is necessary only to lift the connecting rod and give the handle one turn.

By slowly turning the crank by hand, ample speed is obtained at the valve through a gear reduction of three to one.

Track Sand Stored by Compressed Air*

By W. S. Yeates
Georgia Power Company, Atlanta, Ga.

TRANSPORTATION of dried track sand from a central drying plant to elevated steel storage bins in various carhouses and storage yards has been accomplished on the Atlanta railway system of the Georgia Power Company by means of an old car equipped for the purpose with a 12-cu.yd. steel tank, a 160-cu.ft. air



Elevated storage tank filled from loading car

compressor, two 4-in. rubber discharge hose and the necessary pipe lines and valves.

Sand is loaded into the car at the drying plant by inserting a hose into the tank through a cap which projects above the roof and forcing the sand through it by means of air pressure. In unloading the sand from the car to the elevated storage bins, air pressure is introduced above the sand in the tank by means of a pipe line from the compressor to the top of the tank. This pressure in the tank forces the sand through the discharge hose and up into the storage bin.

Each 4-in. discharge hose is provided with an auxiliary air line and a special butterfly valve which is located between the tank and the point at which the auxiliary pipe line is connected to the discharge hose. After the storage bin has been filled, the butterfly valve is closed, stopping further discharge from the tank. The auxiliary air line is then opened to clean the hose and loading pipe of the storage bin of any sand remaining in them. This prevents waste of sand and leaves the hose empty.

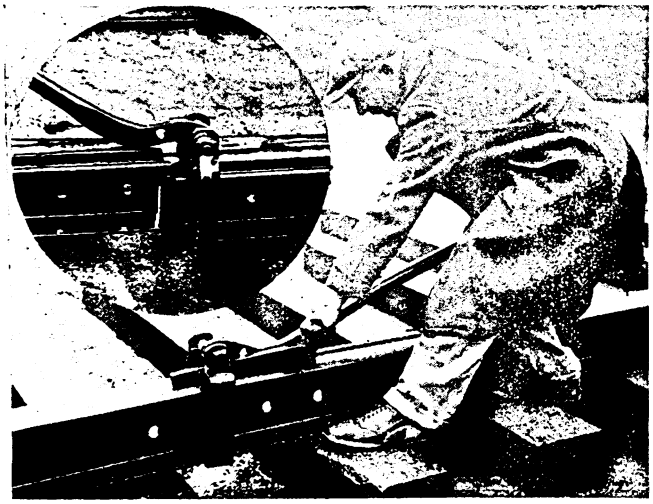
Leveling Bar Facilitates Joint Alignment*

By William Anthony
General Track Foreman Cleveland Railway

LEVELING and aligning of rails at the joints for the installation of splice bars is facilitated by a joint-leveling bar designed by the Cleveland Railway. Previously a track jack and a lining bar were used for



One man can do the entire job of splicing in a short time. The insert shows the leveling device that makes it easy to bring rails to proper alignment before attaching splice bars

the purpose. This method required the services of two men, who often experienced difficulty in bringing the rails to the proper level and alignment. One man can use the new joint-leveling bar, which can readily be placed and fixed firmly in position. The entire work of splicing takes only 1½ minutes with the new device.

The bar, as shown in the illustration, consists of a lever that rests and pivots on the high rail. At the end of the lever is a pair of clamps that fit under the base of the low rail. The fulcrum is in such a position that very little force is necessary to bring the lower rail to the proper level. After the rails have been brought to the same height, a slight lateral motion of the lever is all that is necessary to bring them into alignment. A steel wedge is then placed between the cross member of the bar and the rails, holding them firmly in place and allowing the splicing to proceed without difficulty.

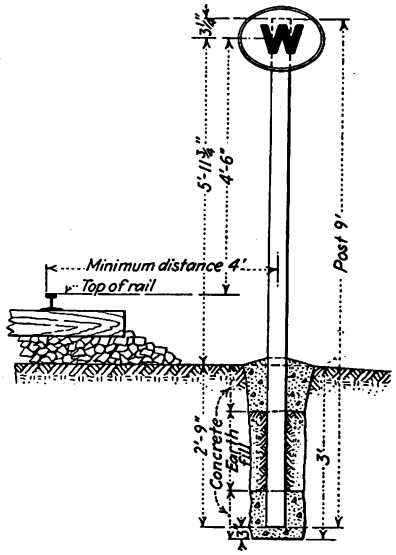
Old Rail Makes Satisfactory Whistle Post

By Joseph M. Hysan
Bridge Engineer United Railways & Electric Company Baltimore, Md.

ON THE Sparrows Point interurban line of the United Railways & Electric Company of Baltimore the conventional wood whistle posts which required frequent repainting and renewals have been replaced by metal posts utilizing pieces of old T-rail. The design consists of an oval-shaped casting of gray iron with the letter "W" and the outer rim raised ¼ in. above the surface. The letter and the outer rim are painted black and

**Submitted in* Electric Railway Journal *Prize Contest.*

Whistle post made of old T-rail is used on Sparrows Point interurban line of United Railways & Electric Company of Baltimore

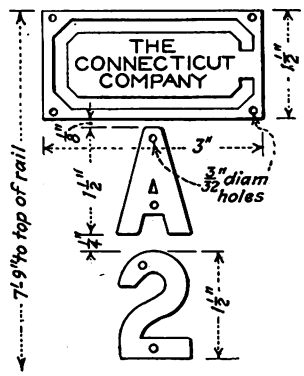


the background white. This disk is fastened to a piece of 60-lb. scrap T-rail cut to proper length and set in concrete. Some of these posts have been in service for about five years and are in perfect condition today.

Marking Wood Poles for Identification

MARKING of wood poles to show ownership and identification numbers is done on the lines of the Connecticut Company by means of aluminum plates, letters and figures. A plate carrying the company's monogram is placed on the pole, in connection with an identification composed of letters and figures. All of these are made of No. 28 gage aluminum sheet. On the plate the letters are raised $\frac{1}{32}$ in. above the body. The single letters and numbers are raised $\frac{1}{16}$ in. and have all corners rounded. They are held to the pole by No. 12 gage oval-head diamond point aluminum nails, 1 in. long. These markers are placed on the street half of the pole, 45 deg.

Aluminum name plates and figures are used to identify wood poles of the Connecticut Company



from the perpendicular line facing the direction of traffic, for span construction. Where bracket construction is used, they alternate every other pole.

Where the Connecticut Company has rights on wood poles of another company, information is given by placing a nail with a raised letter "C" on top, on the pole. These nails are made of No. 3 gage steel wire 2½ in. long. In addition to the identification, a dating nail denoting the year in which the pole is set is driven in each wood pole not higher than 3 ft. above the ground line, on the street side. This practice has been found to be cheaper than painting the markings on the poles.

Digitized by Google

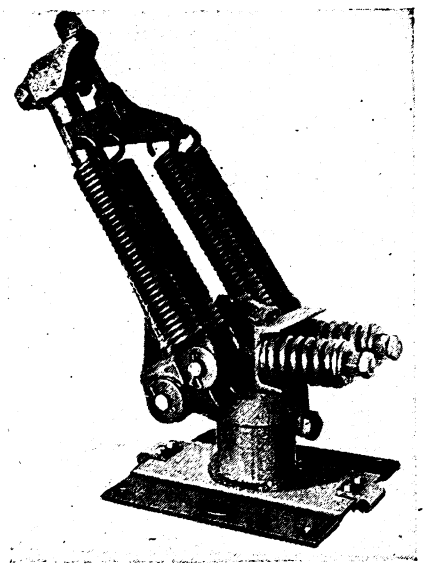
standard-size nut, having the same thread as the jaw, is beveled off. The nut is then screwed on to the bottom truck connection and the jaw screwed on until it comes against the beveled face. The jaw and nut are then welded together. This procedure lengthens the threaded portion of the jaw about 2 in., making it better than new and bringing the bearing on new screw threads of the adjusting bar. If the thread of the nut that has been welded on begins to wear, all that is necessary is to cut off the nut and weld on a new one. This process can be continued as long as the truck connection and jaw remain serviceable.

NEW PRODUCTS for the Railways' Use

Light-Weight Trolley Base

REDUCTION in weight over the lightest of iron bases has been attained by the light-weight trolley base designed by the Westinghouse Electric & Manufacturing Company. It is designated as the Type US-24-A trolley base, and has been produced for use on city, suburban and interurban cars.



This trolley base weighs only 77 lb., complete with spring buffer

Weight reduction has been attained without sacrifice in strength by using rolled steel for the base, heat treated steel tubing for the pole socket, and cast steel for the turret. It is claimed that the reduction in weight of moving parts thus secured quickens the action of the pole and permits lower wheel pressures, while the inherent ability of the steel to absorb shock minimizes noise of operation.

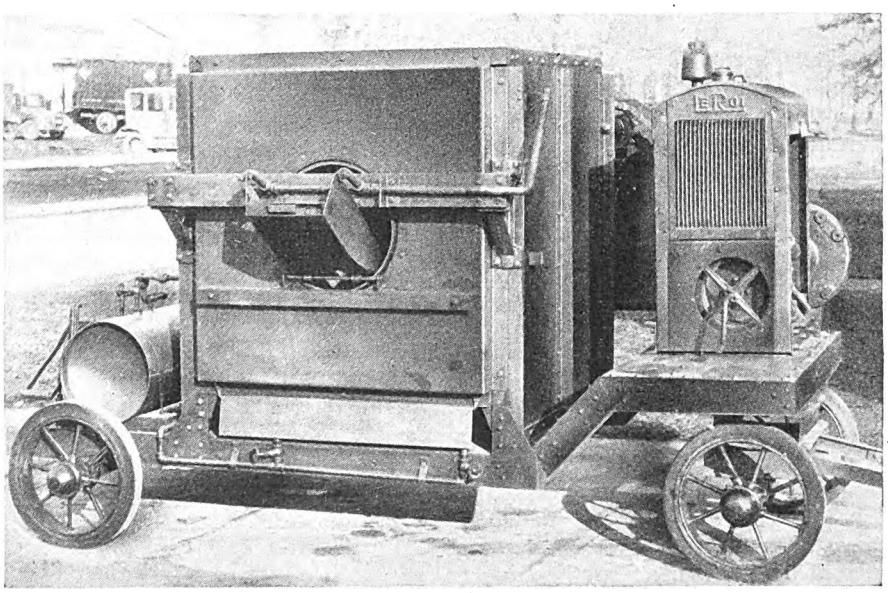
An important feature embodied in the construction is the use of Timken tapered roller bearings, there being two sets, one in the top and one in the bottom of the swivel. They are separated by a spacing bushing, and support the heavy cocking load due to the weight of the pole, harp and wheel and wheel pressure. This bearing pressure is distributed over the entire surface of the tapered rollers in a virtually perpendicular direction to the bearing surface. The tapered roller bearings also support the turret and thus prevent the bulk of the weight from being carried on the axle pin. By loosening one heavy locking screw in the flange of the turret the base can be lifted apart to expose the swivel bearing assembly. A nut on the end of the swivel permits adjustment of bearings.

The trolley base was designed to meet, with ample factor of safety, the maximum requirement of 1,000 amp. for momentary current carrying capacity, 750 amp. for continuous current carrying capacity, and operating wheel pressure on the contact wire up to 35 lb.

Portable Sand Drier and Mix Reheater

THE necessity for rapidly heating and drying sand or stone, or for reheating premixed and natural asphaltic paving materials, can be met with a new type portable heater which has been developed by the White Manufacturing Company, Elkhart, Ind. The heater consists of a rotating drum with internal cascading blades, mounted on self-aligning ball bearings and inclosed in a steel housing. A single-cylinder, 4 hp., radiator-cooled engine rotates the drum by means of a hardened roller chain.

An important feature of this machine is the indirect application of heat from two self-generating kerosene burners, located within the steel housing underneath the rotating drum. These burners apply the heat effectively on the outside of the drum so that no high temperature flame comes in contact with the drying or heating materials. This is said to be especially valuable in handling bituminous mixes, which can be very



Inclosed drum prevents contact of material with flames from burners

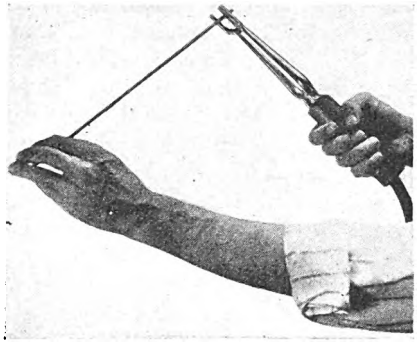
Digitized by Google

easily damaged in open-flame type heating.

The heater is equipped with a steel towing tongue and is mounted on rubber-tired steel wheels with roller bearings. Kerosene is stored in a 30-gal. welded steel tank to which pressure is supplied by a 3-in. hand-operated air pump.

Light-weight Holder for Electric Welding

SEVERAL new features are incorporated in an electrode holder for arc welding brought out by the Stoody Company, Whittier, Cal. While the weight is only 17 oz., the holder is constructed of steel forgings with a turned composition fiber handle, and the conductor cable is attached to it without the usual process of sweating in or soldering.



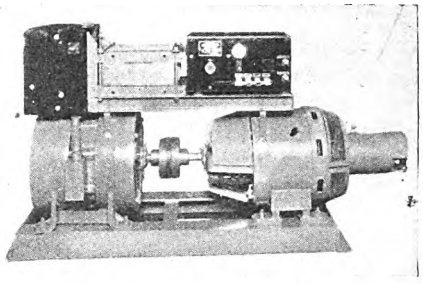
Electrode waste is small with this narrow-jaw holder for electric welding

The three jaws are corrugated, each at a different angle, so that the electrode may be held securely at any working angle. The holder arms are made of a special alloy steel, and are nickel plated and buffed. The spring tension is sufficient to hold electrodes from $\frac{1}{8}$ in. to $\frac{5}{16}$ in. or even greater diameter. The holding jaws remain parallel regardless of the size of the electrode, and the tension pressure extends through the entire length of the prongs.

The principal feature claimed for this holder is the narrow jaw which permits the use of the electrode with a waste of less than $1\frac{1}{2}$ in.

Large-Capacity Welder

DEMANDS for a high welding current to be used with large-size metallic and carbon electrodes have been met by a welder recently placed on the market by the Lincoln Electric Company, Cleveland, Ohio. This welder may be had in either the portable-truck type or stationary-truck type. It is a motor-driven, single-operator, variable-voltage machine, and has a current range of from 180 to 750 amps. The motor and generator are direct connected and the working mechanisms of all controls are contained in a ventilated, inclosed steel cabinet with hand regulators and switches mounted on a panel which forms a side of the cabinet. The control panel contains rheostats, diverter switch, safety starter switch, volt-ammeter and wing nut terminals for cables. The control cabinet is mounted directly over the motor-generator for easy access by the welding operator. This arrangement permits the removal of the motor-generator armature without disturbing any other parts.



Control mechanisms conveniently arranged above motor-generator set for welding

The facility with which the lead cables may be connected to the wing nut terminals lessens necessity for a polarity reversing switch.

Improved Marathon Ear Reduces Wheel and Wire Wear

WITH the purpose of still further reducing the wear on trolley wire, ears and wheels, the Ohio Brass Company, Mansfield, Ohio, has just put on the market a new ear having tapered sides and known as the improved Marathon. In place of the shorter and more abrupt approach-and-leave of the old type ear the improved Marathon has a long, gradual, tapered approach-and-leave. The tapered approach permits the trolley wheel to pass on to the ear without bounding from the wire, to ride easily over the ear and to pass from the ear to the wire without any abrupt pounding action. The whole wheel passage is said to be smooth and continuous.

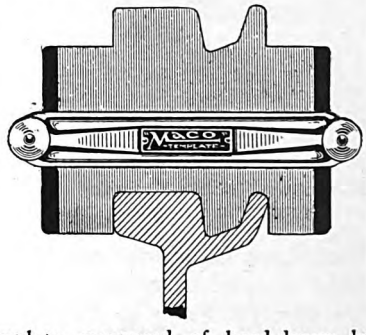
Tapering begins at the end with practically knife-edge thinness and, in the 15-in. ear, extends almost 4 in. toward the center section. Because of the long, tapered approach, it has been possible to increase slightly the section at the center, the point of greatest wear. This makes no appreciable difference in the peening qualities but adds materially to the service life of the ear. The tapering has been effected by means of special milling equipment which cleanly cuts the metal and insures uniform smoothness and precision.

Improved Marathon ear affords easy approach to trolley wheel

Service tests have indicated that because of the smooth wheel passage, arcing and pitting of the wheel, ear and wire have been eliminated with the result that better and longer service is obtained from each.

Maco Template for Registering Rail Contours

DETERMINATION of rail contours is accomplished accurately and easily by means of a registering template made by the American Maco Template Company, Inc., New York City. This is composed of a number of fine strips of hard-drawn brass held in an aluminum frame. The thickness of each strip is 0.007 in. The laminations are held in position by two special clamps which are fitted with sections of corrugated rubber. When a profile is required, all that is necessary is to loosen the screws and gently press the adjustable template against the contour. The result of such pressure is that the laminæ take a perfect outline of the surface against which they are pressed, their extreme thinness materially assisting in the facility and precision of the process. When the impression is complete, the laminæ are held in position by merely locking the screws. From the template thus produced other permanent templates may be made or a record of the section of the profile may be kept and filed for future reference.



Template composed of hard-drawn brass strips facilitates the registering of rail contours

New

Maintenance Contest

to Start Nov. 1

THE fifth annual Maintenance Contest conducted by ELECTRIC RAILWAY JOURNAL in conjunction with the American Electric Railway Engineering Association, will begin Nov. 1, 1930. More interest than ever before was shown in the contest which has just ended, and prospects are bright for keen competition next year. Full details concerning rules, etc., will be given in the October issue.

NEWS *of the Industry*

LATE NEWS

Baltimore, Md.—The Sun Cab Company, which operates a large fleet of taxicabs here, has been ordered by the Maryland Public Service Commission to take out public liability insurance for the protection of its passengers on or before Sept. 8. The order fixes a minimum sum of $10,000 for a single passenger and $20,000 for more than one passenger. The company may, however, as an alternative provide and maintain a bond or cash indemnity reserve fund of not less than $100,000, based on the number of cabs in operation.

✦

San Francisco, Cal.—Seizing the opportunity to secure life insurance at exceptionally low rates by adding to the company free policy a small amount paid voluntarily by themselves, 2,304 out of 2,667 employees of Market Street Railway have taken out additional insurance amounting to about $3,350,500 in protection.

✦

Camden, N. J.—Public Service Coordinated Transport carries passengers from its Jersey Bus Terminal in Philadelphia to Central Airport, Camden, where passengers board the planes and are taken to Atlantic City. Buses are operated from Bader Field in Atlantic City directly to the Public Service Union Bus Terminal in that city. The service was started on Saturday, July 2, and 300 passengers sought to be accommodated. Two trips were scheduled between Philadelphia and Atlantic City. Ten trips were operated. When the service was started it was planned to operate only on Saturdays and Sundays. However, the demand for service has necessitated a daily schedule.

✦

Hartford, Conn.—The Connecticut Company has adopted the one-man system on its Rockville line preparatory to the substitution of buses under permission from the Public Utilities Commission when convenient to the company. The Rockville-Hartford line is divided into three zones.

✦

Chicago, Ill.—Special service direct to the National Air Races at Curtiss-Reynolds Airport was operated by the North Shore Line from Aug. 23 to Sept. 1, inclusive, with reduced round-trip rates. Service by train was to Northfield station on the Skokie Valley route and thence by motor coach to the grandstand.

✦

Haverhill, Mass.—The Massachusetts Northeastern Railway installed bus service on three lines on Aug. 20 under a 5-cent zone fare. It is expected that the lines in the vicinity of Haverhill will be entirely motorized by Sept. 7. Service by bus between Haverhill, Mass., and Plaistow, N. H., will be started on Sept. 3.

Seattle Municipal Having Its Own Troubles

Many Problems Plague City Officials. Employees Again Paid With Warrants Redeemable in Future. Attempt at Refinancing Unsuccessful

SEATTLE'S chances for refinancing its Municipal Railway debt through a new issue of long-time utility bonds are decidedly slender. So Mayor Frank Edwards, prime mover in the refinancing efforts, has admitted after conferences with investment bankers and advisors closely in touch with the bond market.

With the problem again acute because of the railway's inability to cover its current payroll with cash from revenues, and, at the same time, meet minor bond and interest payments, an entirely new program of relief probably will have to be devised.

Efforts have been under way for more than a year to assure a satisfactory market for about $10,000,000 in new street railway bonds, payable in about twenty years. This, it is figured, would wholly retire the balance of nearly $9,000,000 still owing to the Pudget Sound Power & Light Company on the purchase price of the railway system, under a short-term contract which has been temporarily relieved by the moratorium. It was counted upon, also, to provide means of extending street car lines, buy new equipment and rehabilitate the entire system. Mayor Edwards says he has been advised that "a straight out-and-out street railway bond issue would not be attractive to investors under present conditions in Seattle."

Meantime, members of the City Council are considering two plans for relief, one to include an item of about $200,000 in the 1931 city budget to assist the street railway department out of tax funds with the cost of maintaining paving and planking between street car tracks. Councilman Case declares the railway is burdened with the entire cost of maintaining the paving between tracks, whereas it should be required to maintain only about 18 in. along its rails where special paving is laid to permit of easy access to the rails when repairs are needed. He would relieve the railway of the burden of maintenance costs of $403,000 a year on paving between car

The Business Outlook

AFTER about two weeks delay due to drought scare, the signals of the beginning of definite business recovery now flicker faintly amid the encircling gloom. This week nearly every important weekly indicator has turned upward. Steel activity, coal production and carloadings are up more than seasonally; electric power output is increasing slowly; building is resisting seasonal decline; general trade volume is rising nearer to normal levels; and commodity prices have ceased their rapid decline. To carry us beyond the seasonal hump during September, the upturn depends on whether the Federal Reserve will keep the credit clock wound up and whether business brains will jump energetically into the job after Labor Day.—*The Business Week.*

Five-Cent Local Fare Restored in Boston

For an experimental period of 30 days, beginning Sept. 1, the board of public trustees of the Boston Elevated Railway have authorized a reduction in the rate of local fares from 6¼ to 5 cents, without transfers.

The reduction of fare in local fare zones is prompted by the necessity of increasing riding in order to offset, if possible, the loss in riding from the use of the private automobile and present industrial conditions. These two factors together are estimated to have caused a reduction of 1,380,409 revenue passengers, about 5 per cent on the system during July, 1930, compared to July, 1929.

General Manager Dana said:

Under the law, the Boston Elevated must be operated on a service-at-cost basis. A decrease in revenue, due to a reduction in riding, can be met ultimately only through proper economies, or by an increase in the rate of fare, or by increasing riding. A reduction of $2,000,000 in operating expenses during the past three years, resulted in offsetting the reduction in revenues due to the decrease in riding. This reduction in the local fare rate is an effort to increase riding. It is hoped that this change will be successful and that no further adjustment in the rate of fare for local zones will be necessary.

The local rate of fare is of value for short rides throughout the Elevated system. There are 120 routes over which the local rate of fare is in effect. During the year ended Dec. 31, 1929, 56,272,366 passengers were carried at the local rate of fare. This represented almost 16 per cent of the total number of revenue passengers that year.

It is the earnest desire of the trustees to increase riding in local fare zones by offering a fare of 5 cents for such rides. It is hoped that this action will receive the co-operation of the public and that riding will be increased.

The change does not affect the rate of the regular fare or the transfer privileges at the regular fare.

LATE NEWS

(*Continued from Page* 596)

Salt Lake City, Utah.—Trolley buses are to be substituted for trolley cars by the Utah Light & Traction Company on the Capital Street line under an order of the Public Utilities Commission. Service with the new equipment will be in operation from South Temple and Main Streets and to the east side of the Capitol grounds, except during the winter, when the company may restore service by trolley if it so desires.

✦

Los Angeles, Cal.—Permission for the Los Angeles Railway temporarily to discontinue shuttle car operation on Santa Fe Avenue and Mateo Street between First and Seventh Streets and to substitute a bus service in order not to hamper construction of the Fourth Street viaduct has been granted by the Board of Public Utilities.

✦

Columbus, Ohio—Three street cars were destroyed, twenty others were damaged, and the roof burned off the Milo carhouse of the Columbus Railway, Power & Light Company, Aug. 22. The damage to the cars is estimated at $55,000 and to the building at $20,000. The building will be repaired immediately.

✦

Stockton, Cal.—The City Council has adopted the proposed harbor development plan of Colonel Allin, director of the port of Houston, and has authorized City Attorney J. Leroy Johnson to apply to the Interstate Commerce Commission to build a rail extension to the Rough and Ready island area. Thus the city has committed itself definitely to a policy of public ownership and control of railroad facilities' serving the future deep water harbor here.

✦

Springfield, Mass. — The Springfield Street Railway has discontinued bus service between Springfield and Westfield. In 1905 railway service was started between these two cities, but due to lack of revenue cars were withdrawn in 1928. When the new Apremont State Highway was opened only two months ago a bus service was started.

✦

Lawrence, Mass.—The Massachusetts Northeastern Street Railway has been authorized by the Public Utilities Commission to operate buses over twelve routes in Lawrence, Methuen, Merrimac, Amesbury, Haverhill, Salisbury and Newburyport.

✦

New York, N. Y.—The Board of Transportation is pursuing a policy of keeping sidewalks as free of subway entrance encumbrances as possible, especially in congested districts, and has set up a force of engineers to specialize in location and design of such entrances. This policy was applied not only to the new subway system now being built, but to the older lines wherever it was feasible to change locations. As a result, 59 entrances on the new system have been laid out in city parks, malls or through private buildings. In addition to these, 30 stairways that obstructed sidewalks at entrances to existing subways have been relocated on private property.

✦

Gary, Ind.—A new skip-stop system between Broadway and Colfax Street in West Gary and reduced running time between Gary and Hammond is in effect on the Hammond division of the Gary Railways. The skip-stop system eliminates a number of stops through Tolleston and West Gary where city blocks are short and the frequent stops slow up operation. The stops are staggered, eastbound and westbound blocks falling on alternate streets. With the introduction of the skip-stop system and with the improved roadway resulting from reconstruction, running time between Gary and Hammond has been reduced to 45 minutes, five minutes faster than the former schedule.

✦

Lynn, Mass.—The property of the Nahant & Lynn Street Railway, operated between Nahant and Lynn, was purchased at a public auction on Aug. 20, by the Eastern Massachusetts Street Railway for $13,500. The purchase includes the carhouse site, twelve cars and parcels of land along the right-of-way.

✦

Utica, N. Y.—The Public Service Commission has authorized the New York State Railways further to discontinue its shuttle line on Auburn Avenue from the intersection of Genesee Street and Auburn Avenue to the intersection of Prospect Street and Holland Avenue. This further discontinuance is effective until July 1, 1931. Since the suspension of the shuttle line in 1926 the Utica Railway Co-ordinated Bus Line, Inc., has operated buses over practically the same route. The company does not want to abandon the shuttle line altogether because it desires to await the development of the residential section at the end of the line.

✦

Pittsfield, Mass.—The Berkshire Street Railway has applied for a franchise for a cross-over from East Street to West Street here to permit direct connection with the New Haven Railroad, as part of plan of the General Electric Company to lease the route from the Berkshire Street Railway. The General Electric Company plans to direct its freight over the route daily between midnight and 6 a.m.

✦

Chicago, Ill.—The committees appointed to obtain deposit of Chicago Rapid Transit Company securities sent letters on Aug. 18 to all known holders of these securities, requesting deposits. The letters set forth that there is no great hope of an adequate return for the "L" without consolidation with the surface lines, but that with consolidation returns may be materially increased.

✦

Tacoma, Wash.—Bills of the municipal belt line for operation of buses past the obstruction to railroad traffic, caused by reconstruction of the Milwaukee Viaduct, have been passed by the Council at the full figure of $15,498. The bills cover the period of operation of buses from Feb. 10 to May 30, and when the full period of such operation is paid for, the total cost is expected to be $35,000. The cost of bus operation has been a heavy drain on the belt line. The financial straits of the belt line were pointed to as reason for liberal allowance for detouring traffic, and it was also argued, that, as bus service merely in the immediate vicinity of the construction job was impractical in combination with railway service, the belt line had to put in buses to make up the entire run.

✦

Seattle, Wash.—Unable to meet a semi-annual interest and principal payment of $421,360, due Sept. 1, on the purchase bonds, the municipal railway department has petitioned the Council or another loan from city light construction bond funds. The last loan extended to the railway system was from the city water fund, Jan. 1, 1929. It was for $800,000, but has been paid off with funds saved by the two-year moratorium on railway purchase bonds. Meanwhile business and civic leaders demand the withdrawal of the transportation system from politics and the setting up of the system as a separate governmental unit under a non-political commission.

✦

Hamilton, Ont.—The Hamilton Street Railway and the fleet of interurban buses has been offered to the city for $2,500,000 by the Dominion Power & Transmission Company. F. A. Gaby, chief engineer of the Ontario Hydro-Electric Commission, emphasized that the Hydro did not want either the street railway or the buses, but this may not represent the opinion of the full commission.

✦

Holyoke, Mass.—The Holyoke Street Railway proposes to install one-man service on local lines early in September. Veteran employees will be retained according to senority.

✦

Portland, Ore.—The operating department of the Pacific Northwest Public Service Company, has worked out a plan to indicate by colored cards whether a car is a "front" or "rear" entrance car. A bright chrome yellow dash sign on the front of the car indicates "front entrance," loading at the nearside crosswalk. If the dash sign is a rich azure blue in color, that means a "rear entrance" car, and should be boarded on the back platform.

✦

Walworth, Wis.—The Chicago, Harvard & Geneva Lake Railway has applied to the Interstate Commerce Commission for permission to abandon, and sell for dismantling its interurban line between Harvard, McHenry County, Ill., and Fontana, Walworth County, Wis. The company previously has had authorization from the state commission to abandon its passenger service in Illinois. The interurban line's right-of-way is paralleled by a concrete highway on which passenger bus and trucking service is available.

✦

Buffalo, N. Y.—Plans to effect improvements to the Falls View bridge across the Niagara gorge at Niagara Falls, ordered by the Canadian Board of Railway Commissioners are being studied by the engineering staff of the International Railway, owners and operators of the bridge. The commissioners recommend strengthening of the guard rail, the construction of an inner guard rail, the raising of the sidewalks 10 in. above the level of the vehicle section, and the use of a new type of floor construction at both ends of the bridge to prevent skidding when motor cars are halted for customs inspection.

Baltimore Introduces Its New Rolling Stock

First of Order of 150 Cars Placed in Service Under a Rehabilitation Program Following the Recent Favorable Fare Decision

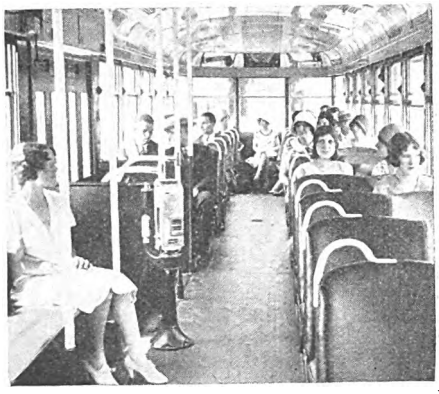
SERVICE with twelve new cars, the first of 150 to be received, was started on Sunday, Aug. 17, by the United Railways & Electric Company of Baltimore on its Madison Avenue line. Modern in their appearance, the cars symbolize the great improvement program instituted by the company, following the favorable fare decision made recently by the United States Supreme Court. The new cars are being delivered as rapidly as possible, and the company expects to have the entire 150 in operation by autumn.

While the cars are designed for one-man, two-man operation, the company started them out with two men, using the conductor as a helper to the operator. Taking a position at the front end of the car instead of at the middle, where the exit is, the conductor assisted the passengers in boarding, made change and instructed them in the use of the fare box. It will thus be possible, when the time comes to run the cars with one man, to do so with less confusion than if the company had started them out as two-man cars, operated on the pay-as-you-pass principle.

Although the weather was rainy and unpleasant most of the day, the line showed an increase in revenue over the corresponding Sunday for last year, when the weather was pleasant. Many favorable comments were made by those who rode on the cars, everyone being highly pleased with the new equipment. Coincident with the inauguration of the vehicles, an editorial, praising the efforts of the United Railways to increase its patronage by betterments, appeared in the Baltimore *Sun*.

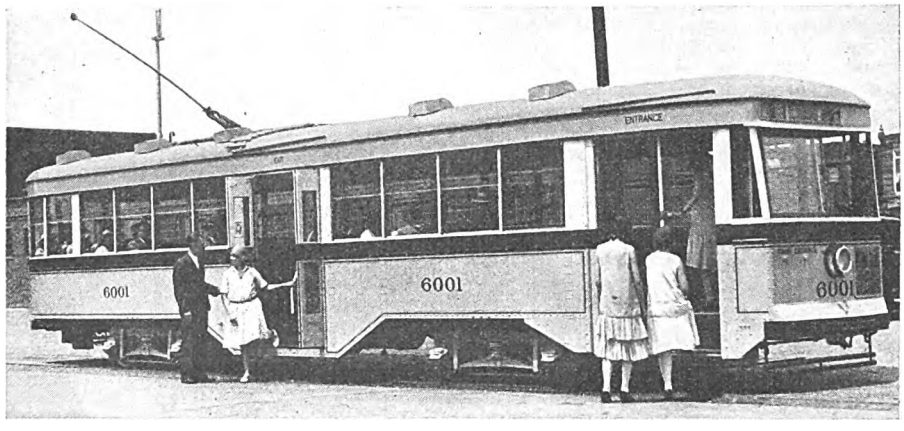
Effective publicity for the introduction of the cars was given in a special "New Car" edition of the company's publication, *Trolley News*. Printed in the form of a miniature newspaper and devoted entirely to the cars, the issue proved a valuable means of stimulating interest among the railway patrons. On the first page appeared a feature item, captioned "Better Transporation for Baltimore Is Promised as New Cars Come to Town," and a facsimile of a letter from the president of the Baltimore Association of Commerce, congratulating the company on the new cars and other service improvements. Individual articles contained in the issue described the use of metal, the low step and floor level, the use of stanchions and handholds in place of car straps, the improved heating and ventilation, the effective lighting system, and the mechanical devices assuring safety. The issue also included several illustrations and statistics regarding the new cars.

Of the 150 cars being built, 100 are being supplied by the J. G. Brill Company and 50 by the Cincinnati Car Corporation. Full details of these cars were given in a comprehensive article in the May, 1930, issue of ELECTRIC RAILWAY JOURNAL. The cars are of the double-truck, single-end, front-entrance, center-exit type, with an over-all length of 46 ft. All of the cars



Leather upholstered semi-bucket type seats, and dome lights add to the comfort and convenience of patrons

are being mounted on Brill 177-E-1 trucks with 26-in. rolled steel wheels. Each car will have four 50-hp. motors, either Westinghouse 516-A or General Electric GE-301. Automatic control of the PCM and VA type will be used, to obtain a smooth acceleration of 3.25 m.p.h.p.s. The total weight is 38,933 lb. and the seating capacity 52.



One hundred and fifty cars of this type are being received by the United Railways & Electric Company of Baltimore. The first twelve to arrive were placed in service on Aug. 17

Trailers Dropped on Lorain Avenue Line in Cleveland

An experiment designed to increase street car riding by giving faster and more frequent service has been started by the Cleveland Railway on the Lorain Avenue line, one of the longest in the city.

The principle is the same as that which has been in effect on the Madison Avenue route of the Chicago Surface Lines since July 19; namely, the substitution of single motor cars for trailers during the rush hours.

Under the new schedules of the Cleveland Railway, the headway is reduced from five to two minutes during the rush hours and the running time is cut from 47 minutes to 42 minutes. The base table running time has been reduced from 44 to 39 minutes and the night running time from 40 to 35 minutes.

The use of single-motor cars instead of trailers will increase operating costs, but it is expected the increase will be more than offset by the saving which will result from closing the Lorain Avenue carhouse.

Safety Congress to Meet in Pittsburgh

An interesting program has been provided for the Electric Railway Section of the National Safety Congress and Exposition, which is to meet in Pittsburgh from Sept. 29 to Oct. 3. The address of welcome will be made by Thomas Fitzgerald, vice-president and general manager Pittsburgh Railways. Other speakers will be Charles Gordon, managing director American Electric Railway Association, who takes as his subject, "Improved Public Relations a Result of Safe Operation," and C. H. Evenson, superintendent of transportation Chicago Surface Lines, whose subject is to be "Accident Prevention Through Supervisory Training." L. G. Tighe, assistant general manager Northern Ohio Power & Light Company, Akron, Ohio, will speak on "Experience of a Public Transportation Company in the Prevention of Street and Highway Accidents," and Chester K. Thomas, division superintendent Chicago, North Shore & Milwaukee Railroad, will discuss "How to Operate a Public Vehicle Safely."

Others who will participate include W. J. McCarter, of the personnel department, Cleveland Railway; E. K. Eastham, safety director St. Louis Public Service Company; Glenn Shaw, superintendent department of accident prevention, Northern Ohio Power & Light Company; Edward McCoy, superintendent employment-instruction Public Service Co-ordinated Transport; L. J. Troy, supervisor of safety Boston Elevated Railway; L. D. Voshall, superintendent of equipment Washington Railway & Electric Company, and John C. Baldwin, Pittsburgh Railways.

Engineers Organize to Seek Formula on Suitable Vehicle

An interesting program of activities for the coming association year was outlined at the first meeting of the new executive committee of the Engineering Association, held in New York Aug. 19. Of particular interest was the proposal, tentatively agreed upon after a lively discussion to appoint an independent committee, reporting to the executive committee, to study all factors which must be considered in determining the relative cost of operation of the three types of vehicles, the street car, the trolley bus, and the motor bus, and, if possible, to arrive at a formula which may be applied to select the proper type of vehicle. The personnel of the proposed committee would embrace engineers whose interests cover phases of practice which a problem of this nature involves.

Making convention programs more interesting was the subject of general discussion. Opinion was divided as to the necessity of presenting all committee reports on the convention floor, but it was conceded that if this is done they should be made as brief as possible. There was general agreement on the desirability of having at least one paper or address on a live subject at each meeting. The view was expressed that by outlining definitely to speakers the phases of a subject to be covered an added interest could be secured and a valuable discussion ensured.

Assignments for the coming year were agreed upon, and committee appointments will be sent out soon. A. W. Baker, engineering secretary, reported that the Manual will be ready for distribution in a few weeks. C. R. Harte presented the report of representatives on American Standards Association committees. This is to be published in summary form in the proceedings. Various routine matters were settled and adjournment taken, subject to the call of the president.

Members present at the meeting included President L. D. Bale, C. H. Jones, P. V. C. See, John Fleming, W. H. Wysor, C. R. Harte, E. M. T. Ryder, H. H. George, A. T. Clark and R. C. Cram.

Rerouting Suggested Under Indianapolis Traffic Survey

Proposals for rerouting of street cars in downtown Indianapolis to relieve traffic congestion are under consideration by the Citizens' Traffic Committee in connection with the redrafting of the city traffic code.

Members of the committee believe that the Indianapolis Street Railway can save money and operate more efficiently by establishing through service on the principal lines, thus eliminating numerous turns in the downtown section.

The committee recently announced plans to conduct a survey in co-operation with the Indianapolis Merchants' Association to determine the method of transportation used by shoppers. The count will be taken at a selected group of stores representative of all lines of business in all parts of the business district. Six-pointed question cards will be used, one being given to each customer as he enters the store. Each detachable point will carry a specific statement as to mode of travel in coming downtown. The one fitting the case will be torn off and deposited in a box. The points are: "Came by auto and parked at curb," "Came by auto and parked at parking lot or in garage," "Walked," "Came by trolley," "Came by bus," and "Came by train."

The count will cover an entire business day, from 9 a.m. to 5 p.m. The returns will be collected hourly and counted by hours and by types of businesses where collected.

Segregation Move in Portland, Ore

Paving a way for the Pacific Northwest Public Service Company, Portland, to separate its power and railway business into two operating subsidiary companies, the City Council has passed an ordinance permitting transfer of the existing franchises. The company expects immediately to proceed with plans for the formation of the Portland General Electric Company to take over the power and light franchises and physical property, and the Portland Traction Company to take over the railway.

Present plans involve an adjustment of the capital structures of the proposed companies requiring a vote of the stockholders and it is understood a special meeting of stockholders is to be called shortly.

Segregation is desired to facilitate compliance with the recent order of the Oregon Public Service Commission, and to facilitate negotiations with the City Council on any possible new railway franchises since the city has a "service-at-cost" franchise in preparation for the consideration of the voters probably in November.

Temporary Financing Proposed for Chicago "L"

The Chicago Rapid Transit has asked the Illinois Commerce Commission for permission to issue $6,872,000 of two-year 6 per cent notes at 96 to pay for the cost of construction work and improvements contemplated in the near future under the terms of the recent unification ordinance.

The principal expenditure will be for purchase of right-of-way for two additional tracks on Garfield Park Branch, Marshfield Avenue to Laramie Avenue, which will cost $2,009,000, and for addition of one track, Garfield Park Branch, Laramie to Marshfield Avenue, including realignment through Sacramento station, which will cost $2,517,000.

COMING MEETINGS

Sept. 5-6 — Central Electric Traffic Association, Wawasee, Ind.

Sept. 10-11 — Central Electric Railway Master Mechanics' Association, Miami Hotel, Dayton, Ohio.

Sept. 11-12—Maryland Utilities Association, leaving pier 19, Light Street wharf, Baltimore, Md., at 3 p.m., Sept. 11, for steamship cruise to Jamestown and Yorktown.

Sept. 17-19—Canadian Electric Railway Association, 26th annual convention, Ottawa, Canada.

Sept. 25 — Pennsylvania Street Railway Association, Casey Hotel, Scranton, Pa.

Oct. 9-11 — Midwest Electric Railway Association, Miami, Okla.

Oct. 22-24—National Transportation Meeting of the Society of Automotive Engineers, Pittsburgh, Pa.

Oct. 29-30—Iowa Electric Railway Association, Des Moines, Iowa.

Suburban Rapid Transit Fare Controversy in Cleveland

Discovery that a heretofore overlooked amendment to the Cleveland Union Terminal ordinance of 1919, giving the city the right to control rapid transit fares within a 15-mile radius of Cleveland, has laid the groundwork for a legal battle between the City Council and the Van Sweringen interests who control both the Cleveland Railway and rapid transit operations in the Cleveland territory.

Protests against the 15-cent rate charged by the Cleveland Interurban Railway on the Shaker Heights line led to the discovery that the Van Sweringen interests plan to charge the same fare on the projected East Cleveland rapid transit line, scheduled to go into operation in a few months, and a projected West Side rapid transit line along the Nickel Plate right-of-way, which it is proposed to put into operation next year.

The East Cleveland commission has voted to file a protest against the 15-cent rate of fare on the East Cleveland line, while attorneys for Shaker Heights residents have petitioned the Ohio Utilities Commission charging that legal steps were not complied with in raising the fare from 10 to 15 cents on the Shaker line.

The Cleveland law department called attention to the provision of the old terminal ordinance, under authority of which the Van Sweringen terminal was built, giving the city the right to fix the rapid transit fares within a 15-mile radius of the terminal and also specifying that the city should have the power to fix stops and that any rapid transit lines established under authority of the ordinance should have provisions for transfers between rapid transit and city cars. None of the rights granted under these provisions have ever been exercised. However, any attempt to enforce these provisions probably would lead to suit on the grounds that there is a conflict between the city ordinance and the utility regulations of the state.

Value of Winnipeg Railway Reported

The present value of the railway property of the Winnipeg Electric Company, Winnipeg, Man., is $17,024,658, according to an inventory and appraisal filed with the Municipal and Public Utility Board. To replace the property with new plant would cost $19,596,915. Distribution of value shows that the company's property has a new replacement cost of $18,259,395, but depreciation cuts this figure to $15,892,819. The report allows $1,770,500 for company's intangible assets as a "going value," because of its patronage and earning capacity. Among larger assets are listed 108 miles of single tangent track. The audit was filed in connection with the plans for an increase in fares and reductions in payments to the city.

Veteran prepared to guide visitors to Boston's Tercentenary

Helping Visitors to Boston

The Tercentenary Committee of the city of Boston and the Boston Elevated Railway on Aug. 18 opened an official booth to give visitors to Boston information on events relating to the tercentenary, and also general information relating to places of historical interest, near-by pleasure resorts, means of transportation and any other information that visitors want.

The booth is located adjacent to the memorial shaft and faces directly the main entrance to the South Station. It will be open from 10 a.m. to 6 p.m. on weekdays. Michael J. Dockery is in charge of the booth. He has been in the employ of the Boston Elevated Railway for 34 years, and for the last six years has been one of the information clerks at the Park Street subway station. The location for the booth was granted by the Boston Terminal Co.

New York's New Subway Nears Completion

Prospects point to the completion of construction work on the new Eighth Avenue subway line in New York City in time to permit the beginning of operation in the Fall of 1931. With the exception of three or four short stretches, the basic construction work has been finished from Chambers to 207th Street.

Mayor Walker and his transit advisors, it is known, regard the question of how the new line will be operated as of vital importance in the pending negotiations for unification of the new subway system with the B.-M. T. rapid transit lines. If the Eighth Avenue line is to be operated next year, it must be decided well in advance whether it will be part of a unified system or turned over to municipal operation, or leased to the B.-M. T. as an addition to the city-built lines operated by that company under Contract 4 with the city.

The most recent rumors are that a plan for operation of the new subway system at a 5-cent fare by a corporation whose shares are controlled by the city, obviating municipal operation or lease to existing traction companies, is being considered by city officials. This proposal is contingent on failure of negotiations to buy B.-M. T.

No Zone Fare Cabs in Cleveland

The Cleveland Railway, which opposed the projected invasion of Cleveland by a fleet of low-fare taxicabs and secured a temporary injunction restraining the city from granting the Zone Cab Company a license, has now won a partial victory.

The court has ruled that the cab company may be granted a license, but that it may not operate under its projected zone fare system. Instead, it must conform to the city ordinance and install meters which calculate the fares mechanically. The decision was handed down by Chief Justice Powell of common pleas court.

George D. McGwinn, vice-president of the Cleveland Railway, said:

"Judge Powell's decision prevents the operation of taxicabs on a zone basis. In obtaining this decision, I believe the company has done its full duty by its partner, the city of Cleveland, and by its stockholders."

Officials of the Zone Cab Company announced that meters would be installed and the cabs would go on the streets shortly.

Toledo Displays Its Wares

Transportation progress in Toledo was featured by the Community Traction Company, Toledo, Ohio, in its booth at the recent Toledo Industrial Progress Exposition. At the back of the display was an illuminated map of Toledo's co-ordinated railway and bus system flanked by a series of interesting pictures selling the idea of modern transportation.

Two motion picture machines were in constant operation One showed "The Story of Local Transportation" and the other action pictures in connection with operation and improvement of the railway. Model cars and buses were used to attract attention to modern equipment in use by the company.

Outside the exposition the company had special buses to connect with its main lines in the heart of the business and hotel district, giving an actual demonstration of service.

Effective display of facilities of Toledo Company for serving the public adequately

New Effort to Reach Equitable Philadelphia Value

A checking up and appraisal of the physical assets of the Philadelphia Rapid Transit Company and underliers has been ordered by the valuation committee of Judge McDevitt's General Transit Conference.

J. A. Emery, vice-president of Ford, Bacon & Davis, Inc., and a member of the valuation committee, will be in charge. He will receive the co-operation of Dr. Milo R. Maltbie, public utilities expert, who has been assisting Comptroller Hadley in his P. R. T. audit.

The purpose is to assist the valuation committee in determining a price to be paid by the city for the P. R. T. and the underliers, as recommended by the General Transit Conference.

The valuation committee was created to establish a "fair price" for the entire transit system. Members of the committee are: Judge McDevitt, chairman; Deputy City Comptroller S. Davis Wilson and Mr. Emery. Joseph Wayne, Jr., president of the Philadelphia National Bank, was named as the fourth member, but resigned because of the press of other business.

At the meeting at which decision to embark upon the appraisal was reached it was agreed that hearings will be resumed in mid-September in the city's equity suit against P. R. T. and the Mitten interests for alleged violations of the 1907 city-P. R. T. transit agreement.

Hearings in the city's suit were suspended in January to permit a survey of the transit situation by a conference of city officials and P. R. T. representatives in order to solve the tangled transit situation.

Upon organization the members of the conference which has come to be known as the General Transit Conference designated four experts to make a survey of the transit situation and to report a plan for its solution. Dr. Maltbie, representing Comptroller Hadley; Mr. Emery, representing Mayor Mackey; Solomon M. Swaab, acting for City Council, and W. K. Myers, vice-president of Mitten Management, Inc., for the transit interests, were the four selected. Their survey crystallized in a plan that the city purchase the entire transit system at a "fair price" as the only possible solution of the muddled transit situation.

They pointed out that at a price of $150,000,000 the city would save $7,319,365 annually in operating the transit system. A price of $200,000,000 would result in a saving of $4,644,635 annually, the experts reported.

Subsequently, Comptroller Hadley announced that he would not approve payment of a price in excess of $150,000,000, while sources close to the P. R. T. and underliers indicated that the minimum acceptable price would be $175,000,000.

It was at this point that the valuation committee was delegated to fix a "fair price" acceptable to both the city and the P. R. T. and underliers. In announcing the new check-up Judge McDevitt said:

We have concluded that we cannot reach a proper determination as to price until a check-up appraisal of the physical assets of the P. R. T. and underliers is completed.

The data to be gathered in such a check-up appraisal will supplement the facts already before the valuation committee. Once this new information is available we will then be in a position to make a report to the general transit conference.

It is our opinion that we will not be in a position properly to discharge our task until the most complete information as to every phase of the transit situation is accurately collated and digested.

In a matter of such vital importance every possible step should be taken to determine the value of the physical assets as well as the earning capacity, present and potential, of the transit system.

The cost of the work will be insignificant in comparison to its tremendous value and importance.

"Faster than We Build Them in New York"

The Chicago Board of Local Improvements has adopted a resolution ratifying the appointment of employees of the advisory subway commission and approving delayed payrolls for these employees. The recent opinion of Corporation Counsel Ettelson that the board should have a governing hand in subway construction was thus carried into effect.

Some authorities in Chicago are holding that substantial improvement in transportation will come before a subway is available. In this connection Alonzo J. Hammond, a prominent engineer, has proposed a plan whereby the capacity of the present "L" structure in the Loop can be doubled by utilizing the Loop structure differently.

When asked whether Chicago's new subway would be ready for the World's Fair in 1933, Robert Ridway, chief consulting engineer, said: "That's faster than we build them in New York."

Seattle Municipal Having Its Troubles

(*Continued from page* 597)

tracks, paying all but $153,000 of this amount out of the city's general budget. He also favors a straight city bond issue of $1,500,000 to provide funds to "buy fast, modern street cars, upholstered and comfortable to ride in."

Another problem is the one of pensions. To settle this matter voters may be asked to decide whether the civil service pension system, now applying to all employed outside the police and fire departments, shall be abandoned so far as the railway is concerned, or whether the railway department's present contribution to the fund shall be assumed by the city taxpayers.

The railway, light and water departments are now matching their employees' contribution to the pension system out of their utility earnings. In view of the railway department's present financial embarrassment, it probably will not be able to continue its pension contributions out of earnings with the extra burden, also, of the 44-hour week and the 4-cent-per-hour increase in wages granted to the railway employees a year ago. The railway's pension requirements for 1931 will amount to $150,000, while the 44-hour week is costing about $45,000 a year and the 4-cent increase about $80,000 a year, all to come out of current earnings even now inadequate.

*The three index numbers marked with an asterisk are computed by Mr. Richey, as follows: Fares index is average street railway fare in all United States cities with a population of 50,000 or over except New York City, and weighted according to population. Street Railway Materials index is relative average rice of materials (including fuel) used in street railway operation and maintenance, weighted according to average use of such materials. Wages index is relative average maximum hourly wage of motormen, conductors and operators on 136 of the largest street and interurban railways operated in the United States, weighted according to the number of such men employed on these roads.

City Begins to Realize on Its Rapid Transit Investment

New York City's entire bonded investment in the Interborough Rapid Transit system, totaling more than $163,000,000, is on a self-supporting basis for the first time since the signing of the dual subway contracts in 1913. The immediate result will be to reduce by at least $5,500,000 the debt-service item in the city's budget for the coming year.

Under the 1913 contract with the Interborough, by which the city contracted to build the lower west side line, the upper east side line and the Brooklyn extensions, the city issued bonds totaling $104,000,000 for its share of construction work. The city was to receive a return of 8.76 per cent on its investment, after the Interborough had deducted enough to cover its rental of $2,600,000 a year for the old subways, its interest on bonds, operating expenses and a preferential of $6,335,000 a year.

For years after the entire system was in operation deficits in the Interborough's preferential, which comes ahead of the city's return, prevented the receipt by the city of any sum at all on its investment. As a result the city had a frozen credit of $104,000,000 in the system, with $5,250,000 going into the budget each year to pay the carrying charges on the bonds, plus an even larger amount to carry the $166,000,000 the city invested in the B.-M.T. system, where a similar financial situation has prevailed.

BOOK REVIEWS

Co-ordinated Transportation

"Co-ordinated Motor - Rail - Steamship Transportation." By G. Lloyd Wilson, Ph.D., Professor of Commerce and Transportation, Wharton School of Finance and Commerce, University of Pennsylvania. D. Appleton & Company, New York. 228 pp., illustrated. Price $3.50.

The thesis presented and supported in this book is that the interest of the shipper, carrier and public are best served if each transportation agency is used in the service to which it is especially adapted and for which it is most efficient and economically equipped. Significance of co-ordinated transportation is described in detail in the first chapter and attention is called to the fact that all transportation agencies have a common interest. This, however, does not necessarily have to be identical. Having discussed the transportation facilities, the author also looks at the terminal problems because here all transportation begins and ends and much of the efficiency and speed of haulage depends upon the management and equipment of the terminal, whether for passenger or freight purposes. Terminal arrangements in New York, Chicago, Boston, St. Louis and Cincinnati, are adequately described, and terminal systems in England and Canada are discussed also. Important problems such as store-door freight service and co-ordinated motor-rail passenger service are treated adequately, while the various layouts of system are illustrated to give the reader a better understanding of the different phases of co-ordinated transportation discussed.

High-Voltage Oil Circuit Breakers

By Roy Wilkins, consulting engineer Pacific Electric Manufacturing Company, and E. A. Creilin, assistant engineer, division of hydroelectric and transmission engineering, Pacific Gas & Electric Company. Published by the McGraw-Hill Book Company, Inc., New York, N. Y. 296 pages, 121 illustrations, price $4.

This volume brings together all the major facts concerning the characteristics and advantages of the principal types of oil circuit breakers.

The authors have set forth in their book a chronological account of the development of the high-voltage oil circuit breaker, a discussion of the theory of its action, descriptions of modern forms and an account of the results of many field tests.

Descriptions of the modern high-voltage oil circuit breakers are given in considerable detail. Recent developments in operating mechanisms designed to meet the demands for greater speed and better control are presented and discussed. Field tests of performance of a number of different breakers are presented and reviewed. The tests made with relatively high charging current are particularly interesting, since such conditions can be obtained only in the field. The authors have treated their subject largely from the standpoint of the user, but the viewpoint of the manufacturer has not been overlooked.

Problems in Public Utility Management

By Philip Cabot, professor of public utility management, and Deane W. Malott, assistant professor of public utility management, Graduate School of Business Administration, Harvard University. Published by the McGraw-Hill Book Company, Inc., 628 pages. Price, $6.

The book consists of a varied selection of cases prepared under the supervision of the department of public utility management, of the Graduate School of Business Administration, Harvard University, from printed reports of court and commission decisions and from information supplied to the authors by the officers of public utility companies. These problems have been selected and prepared primarily for teaching purposes. Nevertheless, public utility officials and their lawyers will find the treatment of the problems by the case method of great interest and value.

The book consists of four divisions, each with an introduction by the authors, setting forth the principles supported in the cases. The readings of the treatment is as follows:

I. Characteristics of a Public Utility.
II. Valuation, Depreciation and Fair Return.
III. Marketing.
IV. Finance.

The authors have assumed the belief that the most urgent engineering problems of public utility management have been solved and that the major task during the next generation will be that of marketing the products of the utility companies. For this reason, they have placed emphasis on the economic rather than on the engineering or administrative side, in demonstrating the complexity of the marketing problems and how the difficulties of public utility rate-making are further complicated by the regulation of prices by state commissions.

Public Utility Control in Massachusetts

By Irston R. Barnes, Yale University. Yale University Press. 1930. 239 pages. Price $3.

Professor Barnes gives the results of an investigation of the practical application of the doctrine of prudent investment theory to the problems of rate regulation. Massachusetts was selected for the study, and the book gives the first compilation of the laws and all the reports of the state. The chapters deal with: the development of regulatory machinery in Massachusetts; statutory control over security issues; statutory control over rates; rate regulation under the federal rule, the investment theory, and the Massachusetts policy; critical appraisal of public utility regulation in Massachusetts.

A Traffic Control Plan for Kansas City

"An Outline of Principles and Practical Methods for Traffic Control of Value to all American Cities." By the Albert Erskine Bureau, Harvard University, Miller McClintock, Director, Civic Department, Chamber of Commerce, Kansas City, Mo. 272 pages, 57 illustrations and charts and 24 tables. Price, $5.

The report shows how the standards and recommendations developed by the National Conference on Street and Highway Safety may be adapted for use in a city with average traffic problems. The report has been prepared with a view, not only of developing a constructive plan of traffic control for Kansas City, but also of presenting principles of traffic relief valuable in any city where problems of street congestion and traffic hazards exist. Numerous graphs and charts are used to portray the findings of the survey. Many of these charts are of an entirely different nature from those used in any similar report previously issued.

Mr. McClintock regards the report as one of the best and, in many ways, the most interesting report on street traffic planning which the Erskine Bureau has yet prepared. While it was compiled primarily for the relief of local street traffic problems, it should be of value to public officials and others interested in traffic conditions in any city. The bureau tried to a greater extent than ever before to use the pictorial or graphic method in presenting essential facts and conclusions. This accounts for the large number of plates included. These should make the work of particular value in other cities, as they reveal in a simple manner the technique which was used. Moreover the book contains a number of new studies never before undertaken in connection with street traffic planning. Among these the exhaustive analysis of retail store sales in relation to various types of transportation patronage should be of special interest.

PERSONAL MENTION

Personnel of Successor Company in Indiana Announced

Henry Bucher, L. M. Brown and J. A. Greenland All Elevated to Important Posts with Indiana Railroad, Now Operating Former Lines of Union Traction

ROBERT M. FEUSTEL, executive vice-president of the Midland United Company and president of the newly organized subsidiary Indiana Railroad, which has assumed control of the properties of the Union Traction Company of Indiana, has announced the appointment of the following officials of the Indiana Railroad and other interurban electric railway lines under the same co-ordinated management:

Henry Bucher, who is manager of the railway department of the Indiana Service Corporation, Interstate Public Service Company and co-ordinated companies, will be vice-president and general manager of the new company in charge of operations.

W. A. Sauer, vice-president, will have general supervision of accounting and financial matters. Walter Shroyer will direct the accounting work, reporting to E. J. Booth, comptroller.

L. B. Andrus, power executive of the Midland United Company, will have charge of the operation of all power stations, substations and transmission lines. F. L. Ray, superintendent of power plants, and J. O. Peniston, superintendent power distribution, will report to Mr. Andrus.

L. M. Brown, general manager of the Interstate Public Service Company railway department, will be general superintendent of interurban lines of the Indiana Railroad as well as the Interstate Public Service Company, Indiana Service Corporation, and Northern Indiana Power Company. C. C. Lentz, superintendent of transportation, will report to Mr. Brown.

J. A. Greenland, who has been superintendent of transportation of the Indiana Service Corporation at Fort Wayne, will be general superintendent of city lines in charge of local operations of the Indiana Railroad at Anderson, Marion and Muncie; of the Indiana Service Corporation at Fort Wayne, Wabash, Peru and Logansport; of the Interstate Public Service Company at Coumbus, Jeffersonville and New Albany, and of the Northern Indiana Power Company at Kokomo.

W. L. Snodgrass, superintendent of traffic of the Indiana Service Corporation, will be general superintendent of traffic of the Indiana Railroad and co-ordinated systems. C. D. Hardin, traffic manager of the Interstate Public Service Company, and F. D. Norveil, general passenger and freight agent of the former Union Traction Company, will report to Mr. Snodgrass.

H. V. Norford, formerly superintendent of maintenance of way of the Indiana Service Corporation, Fort Wayne, will be general superintendent of maintenance of way of the Indiana Railroad and co-ordinated lines. L. A. Mitchell, engineer of maintenance of way, will report to Mr. Norford.

Henry Bucher

Heber LaMonte will be superintendent of motive power of the joint properties, reporting to Mr. Bucher.

E. E. Slick, claim adjuster of the former Union Traction Company, will continue in that capacity, also reporting to Mr. Bucher.

HEADQUARTERS IN INDIANAPOLIS

Operating headquarters of the Indiana Railroad and other lines under the same management will be located in the Traction Terminal Building in Indianapolis. Only the auditing department and division operating staff of the Indiana Railroad will remain in Anderson, Ind., where general offices of the Union Traction Company formerly were located.

With the transfer of the properties of the Union Traction system to the Midland United Company, Harry A. Nicholl, general manager of the Union Traction for 25 years, and C. S. Keever, superintendent of transportation for the past ten years, resigned.

L. M. Brown

J. E. Cullen in Special Baltimore Post

John E. Cullen, who was with the United Railways & Electric Company, Baltimore, Md., from 1918 to 1922, has been appointed technical adviser to the company. Mr. Cullen does not become a member of the company, but will devote a part of his time to the work. President Storrs explained that because of Mr. Cullen's intimate knowledge of conditions in Baltimore and his experience in the utility field be can be of great help on many subjects.

Mr. Cullen has spent many years in the newspaper field, beginning his career in Baltimore. He became managing editor of the *Evening Sun* and later was advertising and business manager of the *New York Mail*. After leaving the United Railways & Electric Company in 1922 he joined the Hearst organization and took charge of the concern's publications in various cities. On two occasions he was publisher of the Hearst newspapers in Baltimore. He also was a member of the general management staff of the Hearst organization.

Several months ago Mr. Cullen entered the investment brokerage business at the head of Cullen & Company, Baltimore.

✦

J. F. Gardiner Publicity Manager for Byllesby

J. F. Gardiner has been appointed advertising and publicity manager of H. M. Byllesby & Company, Chicago.

T. P. Pfeiffer has been appointed advertising manager of the Byllesby Engineering & Management Corporation and Standard Gas & Electric Company.

J. W. Hicks has been appointed publicity director of the Byllesby Engineering & Management Corporation and Standard Gas & Electric Company, also remaining in charge of the publications of these companies issued for executives and employees.

✦

Mr. Mahaffie With I.C.C. Eight Years

Charles Delahunt Mahaffie, ap[pointed by President Hoover to fill the v[acancy on the Interstate Commerce C[ommission caused by the resignation of Co[mmissioner Thomas F. Woodlock, has beer[connected with the commission since 1922 [chiefly as director of the bureau of finance

Mr. Mahaffie was born in Ol[he, Kan., in 1884. He received an A.B. d[gree from Kingfisher College in Oklahon[in 1905, and was a Rhodes scholar from [Oklahoma at Oxford University, England, [rom 1905 to 1908. From 1908 to 1909, [was instructor of jurisprudence at [Princeton University, and later practiced [in both Oklahoma and Oregon. He [tered the government service in 1916 as [licitor of the Department of the Interior [and from 1921 until he joined the com[ission he was an attorney for the United [tes Railroad Administration.

Commissioner Thomas F. Wo[lock, Mr. Mahaffie's predecessor, was a[pointed to the commission by President [olidge in 1925. He was serving his [st term, which would have expired on [c. 31 of this year.

A. R. Hanbury New Assistant Engineer Way and Structures

Arthur R. Hanbury has succeeded H. W. Smith as assistant engineer of the way and structures department of the Kansas City Public Service Company. He has been a member of that organization since May, 1927, when he went to Kansas City as an engineering representative of the William G. Woolfolk Company, for which he inspected and supervised the roadway rehabilitation then in progress. Upon its completion in March, 1928, he was made assistant to John V. McKinney, the executive vice-president of the company.

Prior to becoming a member of the Kansas City railway organization, Mr. Hanbury was associated with various engineering enterprises. During the World War he served with the expeditionary forces in France, being attached to the

A. R. Hanbury

engineer unit, and when peace was declared he had attained a grade of master engineer in the Rainbow Division.

In July, 1919, he became associated with the Southern Pacific Railway as assistant engineer in survey work in California. When this work was successfully finished in 1921 he entered the service of the Illinois Central Railroad as an assistant engineer. This position he relinquished to engage in railroad location work for the Soviet Government in Russia.

Upon his return from Russia Mr. Hanbury became connected with the William G. Woolfolk Company, Chicago. He proved himself so valuable in his work for this company that at the completion of the rehabilitation of the railway he was transferred to the Kansas City Public Service Company as assistant to the executive vice-president.

Arthur R. Hanbury was born in Chicago on June 13, 1897. He was educated in the grade schools of Chicago and was graduated from the Carl Schurz High School of that city. Later he attended Lewis Institute, also of Chicago.

✦

New Officials in Spokane

Frank T. Post was elected president, J. E. E. Royer, general manager, and R. B. Childs, assistant general manager, respectively, of the Washington Water Power Company, Spokane, which controls the Spokane United Railways, at a meeting of the members of the board of the trustees held Aug. 4 in New York.

Mr. Post has been chief counsel of the Washington Water Power Company since 1909, and a vice-president since 1926. He succeeds as president D. L. Huntington, who died last September. Mr. Royer entered the employ of the company in 1907 and became assistant general manager on Nov. 1, 1924. He succeeds the late Miles W. Birkett. Mr. Childs has been a commercial engineer with the company since 1923 and previous to that was in the employ of the Montana Power Company. He was a captain in the 363rd infantry of the 91st division in the World War.

L. W. Chubb to Direct Westinghouse Research

L. W. Chubb, former manager of the radio engineering department of the Westinghouse Electric & Manufacturing Company, has returned to the company as director of the Westinghouse Research Laboratories. For some months past Mr. Chubb had been located in Camden, W. Va., as assistant to the vice-president of the Radio Victor Company. Mr. Chubb is filling the position left vacant by the promotion of S. M. Kintner to assistant vice-president.

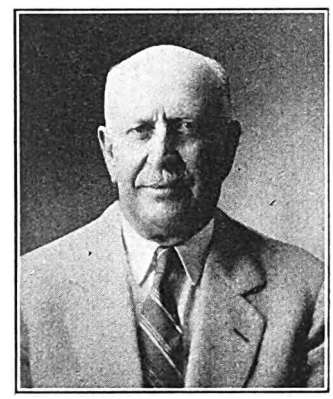
H. A. Nicholl Resigns from Indiana Union Traction

WITH the resignation on Aug. 1 of Harry A. Nicholl, general manager of the Union Traction Company of Indiana for the past 25 years, one of the most prominent and experienced figures in the electric railway industry retired. Extensive and varied business interests require his attention in Indianapolis and Anderson, and Mr. Nicholl does not expect to re-enter the electric railway field for the present. He will continue to reside in Anderson with his wife and family of two daughters. His only son, Thomas H. Nicholl, recently was made superintendent of shops of the Cleveland Railway, Cleveland, Ohio.

The measure of Mr. Nicholl's contribution to the thought of the industry is reflected not only in his work for the Union Traction Company but by his activities in association affairs. He has participated in the work of the American Electric Railway and Central Electric Railway Associations, and in the Central Electric Traffic Association almost since its inception. He was second president of the C.E.T.A., and in 1915 was chairman of the transportation and traffic committee of the C.E.R.A. Since that time he has served in various executive capacities with all three associations, having been chairman of the executive, pick-up and delivery, finance and constitution and by-laws committees of the C.E.R.A. and a member of the rules, insurance and other committees of the A.E.R.A.

Mr. Nicholl has devoted more than 40 years of his life to every phase of the steam and electric railway business. Following in the path of his father, who was a civil engineer with the Illinois Central Railroad, Mr. Nicholl began his career in the late '80's as a transitman for the Chicago & Northwestern Railroad at Chicago. During the next few years he successively held the positions of yard clerk, baggage-master, freight and passenger agent with the Northwestern system and the Illinois Central Railroad, and finally as assistant general freight agent of the Natchez, Columbus & Eastern Railway, a subsidiary of the Illinois Central in the South.

In 1895 Mr. Nicholl withdrew from the steam railway field to become vice-president and general manager of the North Chattanooga Street Railway and Chattanooga & Northside Railway at Chattanooga, Tenn. Three years later he became connected with a financial syndicate



H. A. Nicholl

controlling the Rochester (N. Y.) Railways (now the New York State Railways) as purchasing agent and superintendent of motive power. While occupying these positions he also had charge of construction of the Rochester & Sodus Bay Railway, connecting Rochester with summer resorts on Lake Ontario.

In 1900 he was made manager of the Taunton Street Railway, Taunton, Mass., but the following year he went to Ithaca, N. Y., as general manager and treasurer of the Ithaca Street Railway. After serving in this capacity for two years, Mr. Nicholl joined the Cleveland & Southwestern Railway as general manager. In 1905 he left this company to go to Anderson, Ind., as general manager of the Indiana Union Traction Company, succeeding A. L. Drum, now president of the Eastern Michigan Railways. He was simultaneously named president of the Traction Light & Power Company, a subsidiary serving 50 small communities located along the railway lines and adjacent to them.

At the time Mr. Nicholl entered its employ, the Indiana Union Traction was only two years old, having been incorporated in 1903 as a consolidation of the Indianapolis Northern Traction Company extending from Indianapolis to Peru and other small lines connecting Marion, Muncie, Anderson and Indianapolis. The company was reorganized in 1912 as the Union Traction Company of Indiana, but by purchase and construction was subsequently increased to a system with more than 450

Digitized by Google

miles of track, making it at that time one of the largest interurban electric railway systems in the world.

For many years the railroad enjoyed a profitable business, but under the pressure of paved roads and mounting automobile competition, its revenues began falling off in 1921, and in 1924 Arthur W. Brady, its former president, was appointed receiver. Extensive improvements were effected during the receivership, including the purchase of new all-steel passenger coaches and parlor-buffet cars, but operating deficits continued to grow, until on July 2 of this year the road was sold at public auction to the Midland United Company, Chicago, which controls the Interstate Public Service Company, Indiana Service Corporation and other electric railways serving central and southern Indiana. When the receivership was dissolved and the property was deeded to its new owners, Mr. Nicholl resigned his position as general manager.

Mr. Nicholl was born in 1862.

✦

S. Johnson, Jr., Bendix-Westinghouse Chief Engineer

S. Johnson, Jr., has been appointed chief engineer of the newly formed Bendix-Westinghouse Automotive Air Brake Company at Pittsburgh. In assuming his new responsibilities, Mr. Johnson has, as a background, many years of service and a broad experience in automotive circles.

Last July Mr. Johnson went to Pittsburgh as general engineer for the automotive division of the Westinghouse Air Brake Company. Previous to this time he had served successively in the capacity of inspector, mechanical expert, assistant district engineer, and service engineer over a period of six years, during which time he was identified with the Chicago office of the automotive brake division.

Mr. Johnson is a recognized authority on air brake equipment as applied to modern automotive transportation and is widely known by those closely associated with the industry. He was graduated from the University of Michigan with the degree of mechanical engineer.

✦

J. Franklin Pond Made Manager at Petersburg

J. Franklin Pond, for many years superintendent of the Petersburg division of the Virginia Electric & Power Company system, has been promoted to manager of the Petersburg and Hopewell division of the company. Mr. Pond joined the company in July, 1903, as time keeper on construction work. Since that time he has worked his way up through the various branches of both the transportation and the light and power departments.

Simultaneously with his own promotion, Mr. Pond has announced the following changes in the staff of the Petersburg and Hopewell division:

C. L. Longanecker, who joined the organization in December, 1925, as distribution engineer, has been made superintendent of the electric department.

J. J. Duell, who entered the service in 1903, leaves his position as railway and bus dispatcher to become superintendent of the transportation department.

R. M. Bush, who joined the organization as a draftsman, and who has been assistant distribution engineer since June, 1929, has been promoted to distribution engineer.

T. R. Langan

T. R. Langan Promoted by Westinghouse Company

C. E. Stephens, vice-president, Westinghouse Electric & Manufacturing Company, announced, on Aug. 10, the appointment of T. R. Langan as assistant northeastern district manager of the Westinghouse organization.

Mr. Langan has been with the Westinghouse company for more than twenty years. Starting as an apprentice in the engineering department, he advanced through the construction, service and sales departments of the company to the office of manager of the transportation division of the Northeastern District which office he held at the time of his promotion. He has been identified with the major high-voltage alternating-current railroad electrifications in the United States, and when the New York, New Haven & Hartford Railroad system was electrified, Mr. Langan acted in a supervisory capacity on this installation for three years.

Before going to the New York office, Mr. Langan served the Westinghouse company in Philadelphia, Baltimore, Buffalo and was manager of the Syracuse office.

Mr. Langan will make his headquarters at New York. He will continue to function as manager of the transportation division of the northeastern district.

✦

Well-Known Engineer With Fairmont Railway Motors

H. W. Protzeller has been appointed engineer of maintenance of equipment of the Fairmont Railway Motors, Inc., Fairmont, Minn., makers of section motor cars and an extensive line of other railway supplies. He has long been connected with electric railway work, specializing in railway maintenance equipment and labor-saving devices for handling railway roadbed problems. In the past ten years he has been granted 42 patents on equipment of this kind.

H. W. Protzeller

Mr. Protzeller was graduated from Lehigh University, specializing in electrical and mechanical engineering. This training he supplemented by taking the graduate test course of the General Electric Company. With the General Electric Company he spent several years in the construction department installing railway equipment. He served as assistant superintendent of the Twin City Rapid Transit Company at Minneapolis for three years, and as general superintendent of transportation of the St. Mary's Traction Company at Sault Ste. Marie, Mich., and Ontario.

Following two years at Sault Ste. Marie, he served another two years as consulting engineer for electric railways in Minnesota, Michigan, and Illinois. He assisted in organizing and helped to build the Minnesota Northwestern Electric Railway, and operated that property as general manager for eight years. More recently he has acted as development engineer of the O. F. Jordan Company, East Chicago, Ind. His service with that company covered a period of six years.

✦

John F. McCabe Relinquishes His Springfield-Worcester Duties

John F. McCabe, purchasing agent for the Springfield and the Worcester Consolidated Street Railways, has completed his service for the companies, with the discontinuance of the companies' purchasing departments and the combining of their functions with those of the New York, New Haven & Hartford Railroad in New Haven. His assistant, James E. Meehan, is being transferred to the purchasing offices in New Haven.

Mr. McCabe had been in electric railway work for nearly 40 years. He started as clerk in the storekeeper's department of the West End Street Railway in Boston in 1891. From there he was transferred to the auditor's office and later to the president's office. From 1893 to 1901 he was in charge of the department of tracks, accounts and division correspondence.

On leaving the company at Boston he became chief clerk to R. T. Laffan, general superintendent of the Worcester Consolidated Street Railway, and in 1920 he was given the title of purchasing agent. Later the purchasing activities of the Worcester and the Springfield companies were concentrated in Springfield.

✦

P. S. Arkwright Heads N.E.L.A. Policy Committee

P. S. Arkwright, president of the Georgia Power Company, Atlanta, Ga., has been reappointed chairman of the public policy committee of the National Electric Light Association. Mr. Arkwright first was appointed to the chairmanship of this committee by M. S. Sloan, former president. As chairman of the public policy group, Mr. Arkwright has an important part in the affairs of the association. During the past year, the task of the committee was exceptionally difficult, and Mr. Arkwright's reappointment is regarded as a distinct honor. Mr. Arkwright was formerly president of the association.

W. B. Spencer in New Post at Providence, R. I.

William B. Spencer, director of public relations for the United Electric Railways, Providence, R. I., is also to fill the newly created post of traffic manager. Mr. Spencer will have full charge of the operation of the transportation department.

G. B. Merchant, paymaster, and R. H. Matthews, tax agent, have been retired on pension by order of the board of directors. Both have served the company many years.

The office of general superintendent of transportation is abolished and the incumbent, J. A. Lockhart, has been made assistant claim agent. He will continue as head of the operating staff.

R. W. Hayward, formerly associated with the claim department, is appointed safety manager.

A department of research is created, and H. S. Thorsen, supervisor of schedules, is made a member of the new department.

Mr. Spencer has been prominently identified with many local civic projects, having served as president of the two largest civic clubs in Providence. He is also well known locally as a public speaker. He has a long record of service with the United Electric Railways, having entered the service of its predecessor, the Rhode Island Company, on Aug. 7, 1907, as office boy in the accounting department.

After that he was successively night clerk at one of the carhouses, clerk in the main office of the transportation department (working as both motorman and conductor in his spare time, to round out his street railway experience). In 1913 he was appointed chief clerk in the transportation department. The same year, he was also placed in charge of publicity and public relations, as assistant to the president, but in 1928 was appointed executive

W. B. Spencer

assistant to the vice-president and general manager carrying responsibility for publicity, public relations, safety and other matters.

To help fit himself for his successive promotions Mr. Spencer supplemented his early schooling by attending business college and by taking extension courses at Brown University, so directing his studies along cultural and practical lines as to stand him in good stead in his work with the railway.

From office boy in 1907 to executive in 1930 at the age of 37 and in a period of 23 years is Mr. Spencer's record, the more remarkable because of the wide range of his work and the exacting nature of many phases of it.

✦

Thomas H. Nicholl Now In Important Cleveland Post

Thomas H. Nicholl, who succeeds Terance Scullin as superintendent of buildings and equipment of the Cleveland Railway, Cleveland, Ohio, joined the research department of the company at Cleveland in 1929. Before that he had been superintendent of motive power of the Union Traction Company of Indiana.

From September, 1914 to 1916, Mr. Nicholl was engaged as light and power solicitor with the Traction Light & Power Company, Anderson, Ind. In May, 1917, during the World War, he entered the First Army Officers Training Camp at Fort Benjamin Harrison. Upon completion of this training course he received a commission as Captain of the Tenth United States Infantry, where he served through the duration of the war.

Mr. Nicholl's first position upon leaving the army was with Ball Brothers, Muncie. He next was employed as manager of the Komo Chemical Company, Kokomo, where he remained until his resignation in August, 1922, to accept a posititon as acting superintendent of motive power with the Union Traction Company of Indiana, in which capacity he continued until he joined the railway in Cleveland. During the past year or two Mr. Nicholl has been active in the Central Electric Master

T. H. Nicholl

Mechanics Association, being its first president. Subsequently he served as chairman of the standardization committee and as a member of the handbook committee of that organization.

Mr. Nicholl was born at Baltimore, Md., on Dec. 11, 1893. He was educated at the University of Michigan.

OBITUARY

W. N. Ryerson

William Newton Ryerson, president of the Trojan Engineering Corporation, New York, and a director of the People's Light & Power Corporation, New York, died recently. Mr. Ryerson was born in New York City, Dec. 7, 1874. Following his graduation from the Columbia School of Mines, he entered the employ of the Sprague Electric Elevator Company, Bloomfield, N. J., serving on electrical testing and drafting from November, 1896, to January, 1898. In the same year, 1898, he worked as draftsman for the Western Electric Company, New York, and as assistant to the chief engineer of the Waldorf Astoria Hotel.

In October, 1898, he became associated with the Metropolitan Street Railway, New York, on construction and power work and substation operation, but resigned from the company in June, 1901, to go with the Manhattan Railway as chief operator of its steam electric generating station. His chief interest at that time was electric railways and subways. In October, 1901, he became superintendent of the substations for the Interborough Rapid Transit. In 1905 he was made assistant superintendent of construction for the Niagara Construction Company, and later in the same year, superintendent of construction for the Ontario Power Company, Niagara Falls, Ont., a position he held until January, 1909.

It was then that he became general manager and chief engineer, and also a director of the Great Northern Power Company, Duluth, Minn. He was in this position more than thirteen years. About the time the Duluth properties were acquired by the Electric Bond & Share Company, Mr. Ryerson left to form a connection with Day & Zimmermann of Philadelphia, as assistant manager of the public utility management department, where he supervised the details of operation of all the utility properties, budgets, new business, rates, public relations, accounting and major construction progress.

In January, 1925, the United Gas Improvement Company of Philadelphia, made him assistant to vice president, in charge of operations and engineering. When the Trojan Engineering Corporation was organized in September, 1928, Mr. Ryerson became its president, which position he held at the time of his death.

✦

H. R. Wair

Harry R. Wair, vice-president and general counsel for the Northern Indiana Railway, Inc., South Bend, Ind., died July 11. Mr. Wair had been legal counsel for the street railway and interurban properties in and about South Bend for 35 years.

Upon the reorganization of the street railway property to the Northern Indiana Railway, Inc., his long years of service and outstanding activity in the building up of street railway service in South Bend brought him the appointment as vice-president of the new company.

Mr. Wair was born in September, 1871. In addition to his activity in the railway, he was one of the most prominent attorneys in South Bend, being counsel for many of the large corporations in Northern Indiana.

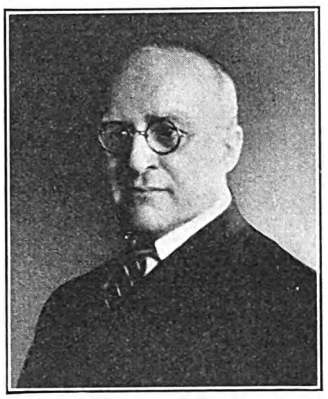
James Carey Davis

James Carey Davis, advisory operating vice-president of the American Steel Foundries, Chicago, Ill., died at Mackinac Island on Aug. 10, aged 65 years.

For seventeen years Mr. Davis was associated with the Sargent company. In 1896 he became general superintendent of operations, in which position he remained until 1901 when he accepted a similar position with the Leighton & Howard Steel Company, St. Louis. He remained in this capacity until both companies were absorbed in 1902 by the American Steel Foundries. He then became western district manager and in June, 1905, was transferred to the Chicago office as assistant to the first vice-president in charge of



J. C. Davis

operations. In 1912 he was elected fourth vice-president of the company, in charge of foundry operations, and continued to occupy that position until March 21, 1929, when he was elected advisory operating vice-president.

Scott H. Blewett

Scott H. Blewett, general agent in St. Louis for the American Car & Foundry Company, died on July 24 following a long illness. Mr. Blewett joined the company as a general agent 35 years ago. Prior to that he was principal of two public schools in St. Louis. He was born at Georgetown, Ky., on Nov. 28, 1851, and was graduated from Colby University, Waterville, Me. For four years after leaving college, he was connected with a publishing concern in Cincinnati. He went to St. Louis in 1874. In 1880 he left the public school system there to become general superintendent of the Scruggs-Vandervoort-Barney Dry Goods Company with which he continued until he joined the American Car & Foundry Company in 1894.

✦

Thomas H. Rowland, one of the organizers of the company which constructed the first street railway line—a steam tramway—to reach from Kansas City, Mo., into the newly platted suburban districts of Kansas City, Kan., died in Santa Ana, Cal., recently.

✦

Dimmitt Elwood South, manager of the office of the Georgetown, Portsmouth & Cincinnati Traction Company at Bethel, Ohio, and former employee of the United States Treasury, is dead.

INDUSTRY MARKET AND TRADE NEWS

Delivery of New York Subway Cars Begins

Ten of an order of 300 new cars for New York's new subway system were delivered in the first week in August to the 207th Street yards, where motors and electrical equipment will be installed. More than 1,000 workmen are engaged in filling the city's $9,000,000 order at the Berwick, Pa., shops of the American Car & Foundry Company, and deliveries will be made from time to time as the units are completed.

Painted an olive green and bearing the name "City of New York" along the side, the new cars embody in their design several original features of construction. Four pairs of double doors on each side, with each opening 3 ft. 10 in. wide, allow entrance and exit in eight lanes, and are expected to facilitate the interchange of passengers at station stops. Quick dispatch will be further expedited by an improved door mechanism, which will prevent the holding of cars by delayed passengers. If the door, in closing, strikes any object, it halts, but does not completely reopen as do the doors on the I.R.T. trains. When the object is removed the door closes. The new cars have no vestibules.

New Cars a Substantial Improvement Over Present Models

Fully equipped, with motors, the new cars cost approximately $38,000 apiece. Each car is a complete unit and none of the trailer variety are being purchased by the city. Cars are 60 ft., 6 in. long, 9 ft. 2 in. longer than the I.R.T. cars and about 7 ft. shorter than the single steel cars used by the B.-M.T. The triplex B.-M.T. cars are 137 ft. long. I.R.T. cars cost approximately $26,000 and triplex B.-M. T. cars in the neighborhood of $75,000.

The new cars will seat 60 passengers and have a total capacity of 280. This compares with a capacity of about 600 in the B.-M.T. triplex units, and is more than the comfortable capacity of the I.R.T. cars. Station platforms on the new city subway have been designed to accommodate trains of eleven cars, longer than either the B.-M.T. or I.R.T. trains.

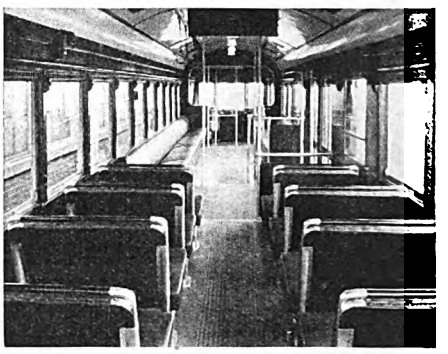
Maximum speed of the cars is between 45 and 50 m.p.h. Automatic, quick release, electro pneumatic brakes should stop them within 500 ft. when operating at 40 m.p.h.

All cars are equipped with multiple-unit door control, with only three men needed to operate a train—a motorman, a conductor and a rear guard.

New Street Cars Arrive in Detroit

The first of an order of 130 street cars, ordered earlier in the year from the St. Louis Car Company for the City of Detroit Department of Street Railways, was delivered in that city on Aug. 11. The remaining cars are to be shipped at the rate of six each week until the order is completed.

Costing approximately $13,500 each, the new cars are of the single-end, double-truck, front-entrance, center-exit type, arranged for two-man operation and seating 52 passengers. Orders for motor and control equipment were divided equally between the Westinghouse and General Electric companies.



In addition to leather upholstered seats, ample standing capacity is provided in new Detroit cars

Oklahoma Railway Awaits New Cars

Delivery is soon to be made by the St. Louis Car Company of ten one-man, single-end, double-truck passenger cars which were ordered last April by the Oklahoma Railway for service in Oklahoma City. The new cars will be of all-steel construction, with arch roofs, and will weigh approximately 25,000 lb. Length over all will be 37 ft. 5 in.; length over body posts, 27 ft. 2 in., and over-all width 8 ft. 4 in. Motors and air brake equipment are to be supplied by Westinghouse, and trucks are of the St. Louis Car Company Type GR-54.

Other specifications are as follows:

Armature bearings	Plain
Car signal system	Faraday high voltage
Compressors	Westinghouse D.H.-16
Conduit	Flexible
Control	Westinghouse K-35
Curtain fixtures	National Lock Washer Co.
Curtain material	Pantasote
Door mechanism	National Pneumatic
Doors	Folding
Fare boxes	Johnson
Finish	Duco
Hand brakes	St. Louis Car Company-Harmon type
Heaters	Consolidated
Headlights	Golden Glow SM-95
Interior trim	Mahogany
Journal bearings	Plain
Journal boxes	St. Louis 4 7/16 x 4 in.
Lamp fixtures	Westinghouse
Roof material	Wood, canvas covered
Sash fixtures	Adams & Westlake
Seats	St. Louis
Seat spacing	29 in.
Seating material	Rattan
Slack adjusters	St. Louis
Steps	Folding
Step treads	St. Louis
Trolley catchers	Ohio Brass
Trolley base	Westinghouse
Trolley wheels	Westinghouse
Wheels	Steel, 26 in. diameter
Wheelguards	St. Louis

New Cars for Edmonton Property

Edmonton Radial Railway, Edmonton, Alta., has placed an order with the Ottawa Car Manufacturing Company for five double-truck steel motor cars, equipped with safety features, for one-man operation in city service. General dimensions of the new cars are: length over all, 46 ft.; length over body posts, 30 ft.; height, rail to top of roof, 10 ft. 6 in.; width over sheathing, 8 ft. 3 in. Total weight will be approximately 38,675 lb., made up as follows: car body, 19,000 lb.; air brake equipment, 2,200 lb.; electrical equipment, 7,400 lb.; trucks, 10,075 lb. Seating capacity will be 51 passengers.

The roof is to be of plain arch type, with steel carlines. Cars will be equipped with double folding doors at the front, and a treadle-operated exit door near the center. The forward door of the pair at the front will be for entrance, and the other will be for exit purposes. The front doors will be operated by folding door engines. Haskelite will be used for interior finish, such as curtain boards, waist paneling and bulkhead lining.

Electrical equipment will include four GE-247-J, 40-hp. motors. Canadian General Electric Company is to supply air brake equipment and safety car control equipment with selective valve and treadle for center doors. Trucks will be of Canadian Car & Foundry Company's design, with 5-ft. 4-in. wheelbase, and with cast-steel bolsters and patented spring-tension, drop-forged, case-hardened link bolster guides. Axles will be A.E.R.E.A. standard forged steel type, with 4-in. diameter motor bearings, Journal bearings will be of the roller type, and the wheels, of rolled steel, will be 26 in. in diameter.

Other specifications are as follows:

Car signal system	Faraday
Curtain fixtures	National Lock Washer Co.
Curtain material	Pantasote
Destination signs	Keystone
Fare boxes	Cleveland No. 5
Hand brakes	Peacock staffless
Headlights	Ohio Brass Company
Headlining	5/16 in. Agasote
Interior trim	Birch
Painting scheme	Red, cream trim
Roof material	Wood, canvas covered
Seating material	Leather
Step treads	Honeycomb
Trolley catchers	Earll No. 10
Ventilators	Nichols-Lintern
Wheelguards	H-B life guards
Special devices	Nichols-Lintern air sand hoppers

Dodge Brings Out New Models

Two new body designs, each of 21-passenger capacity in a new 172-in. wheelbase chassis, as well as changes in power plants of existing models have been announced for production by Dodge Brothers. The new chassis is of the conventional type, powered with an eight-cylinder 3½x5-in. engine of 384.84-cu.in. displacement, which develops maximum of 120 hp. at a speed of 300 r.p.m.

Body designs are radical in appearance in that the fronts have been designed to produce less wind resistance. At the same time the driver is moved up alongside of the engine so that 20 in. of body seating area has been released for widening out seat centers and to give more comfortable wheelhouse seats.

A single body shell is designed to be used for either parlor car or city service. In the latter service, doors are of the double jacknife type, folding inward, with a rear exit door cut in behind the rear axle on the right-hand side. Both of these doors are operated by vacuum engines under the control of the driver by a four-position lever control valve. The first position opens the front service door, the second position is neutral, while the third position opens the rear exit door. Thus the rear door opens last and must be closed prior to operation of the front service door.

As for weights, the chassis tips the scales at 7,500 lb. The parlor car, ready for service with full complement of gasoline, spare tires, etc., weighs 12,000 lb., while the city service vehicle weighs 500 lb. less, or 11,500 lb. Equivalent weight on a per seat basis for the parlor car is 572 lb. and for the city bus, 547 lb.

Recent Bus Deliveries to Electric Railways

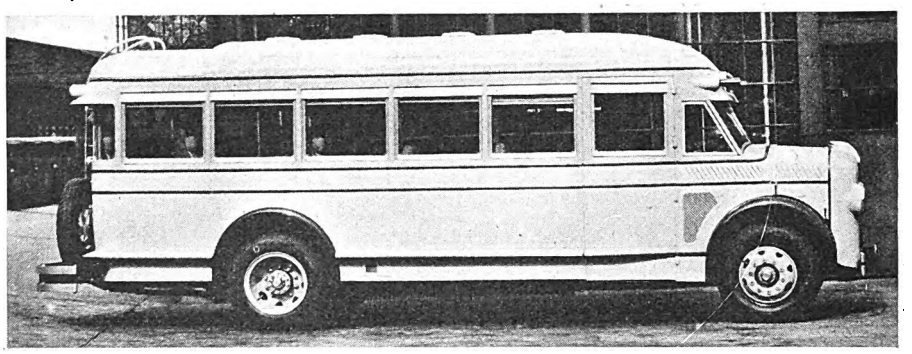
The General Motors Truck Company announces the delivery of 30 Yellow Coaches to electric railways, divided as follows: Twelve double-deck gas-electric coaches to the Baltimore Coach Company; twelve Type Z 38-passenger city service coaches to New Orleans Public Service, New Orleans; ten additional Type Z 29-passenger city service coaches to the Connecticut Company, New Haven; two additional Type Z 29-passenger city service coaches to the Delaware Bus Company, Wilmington, Del.; and two each of the Type U 21-passenger city service coaches were delivered to the Mississippi Valley Electric Company, Iowa City, Ia., and to the Beaver Valley Motor Coach Company, Pittsburgh.

The Eastern Massachusetts Street Railway has accepted within the past month six A.C.F. buses of the 40-passenger all-steel Metropolitan type, and five White Model 65A buses. Other A.C.F. deliveries include thirteen 40-passenger all-steel Metropolitan coaches to the United Electric Railway of Providence, R. I., and two 23-passenger street car coaches to the Triple Cities Traction Company, Binghamton, N. Y.

The White Company reports 21 bus deliveries for the month of July, among which were one White Model 54 and one White Model 54A to the Boston, Worcester & New York Street Railway, Framingham, Mass.; two White Model 65 to the Wisconsin Public Service Corporation, Green Bay, Wis.; one White Model 54A to the Brooklyn Bus Corporation, Brooklyn, N. Y.; three White Model 65A to the Evansville Suburban & Newburgh Railway, Evansville, Ind.; and eight White Model 65 to the Aronomink Transportation Company, Upper Darby, Pa.

Twin Coach Corporation also reports for the month of July one trolley bus to the Brooklyn & Queens Transit System, Brooklyn, N. Y.; three urban buses to the Milwaukee Electric Railway & Light Company; eight urban buses to the Aronomink Transportation Company, Upper Darby, Pa.; and two urbans to the United Electric Railways, Providence.

Deliveries by the Mack International Motor Truck Corporation of recent date consist of one Model BC, 29-passenger city-type bus to the Holyoke Street Railway, Holyoke, Mass.; one Model BC and one Model AB city-type bus to the Fonda, Johnstown & Gloversville Railroad, Gloversville, N. Y.



Reduced wind resistance and increased comfort of wheelhouse seats feature radical body designs incorporated in new bus models

Electric Railway Material Prices—September, 1930

Metals—New York

Copper, electrolytic, delivered, cents per lb.	10.75
Lead, cents per lb.	5.00
Nickel, cents per lb., ingot	35.00
Zinc, cents per lb.	4.35
Tin, Straits, cents per lb.	30.00
Aluminum, 98 to 99 per cent, cents per lb.	23.30
Babbitt metal, warehouse, cents per lb.:	
Commercial grade	37.00
General service	31.00

Bituminous Coal

Smokeless mine run, f.o.b. vessel, Hampton Roads, gross tons	$4.15
Somerset mine run, f.o.b. mines, net ton	1.75
Pittsburgh mine run, Pittsburgh, net ton	1.40
Franklin, Ill., screenings, f.o.b. mines	1.50
Central, Ill., screenings, f.o.b. mines	1.15
Kansas screenings, Kansas City	1.75

Track Materials—Pittsburgh

Standard steel rails, gross ton	$43.00
Railroad spikes, drive ⅝ in. and larger, cents per lb.	2.80
Tie plates (flat type), cents per lb.	2.075
Angles bars, cents per lb.	2.75
Rail bolts and nuts, cents per lb.	3.90
Steel bars, cents per lb.	1.70
Ties, white oak, Chicago, 6 in. x 8 in. x 8 ft.	$1.40

Hardware—Pittsburgh

Wire nails, base per keg	$2.10
Sheet iron (24 gage), cents per lb.	2.45
Sheet iron, galvanized (24 gage), cents per lb.	3.05
Galvanized barbed wire, cents per lb.	2.80
Galvanized wire, ordinary, cents per lb.	2.80

Waste—New York

Waste, wool, cents per lb.	12.00 to 15.00
Waste, cotton (100 lb. bale), cents per lb.:	
White	9.00 to 13.00
Colored	5.00 to 7.00

Paints, Putty and Glass—New York

Linseed oil (5 bbl. lots), cents per lb.	13.3
White lead in oil (100 lb. keg), cents per lb.	13.75
Turpentine (bbl. lots), per gal.	0.48
Putty, 100 lb. tins, cents per lb.	5.725

Wire—New York

Copper wire, cents per lb.	12.75
Rubber-covered wire, No. 14, per 1,000 ft.	$5.05
Weatherproof wire base, cents per lb.	4.89

Paving Materials

Paving stone, granite, 5 in., f.o.b.: New York—Grade 1, per thousand	$150.00
Wood block paving 3½, 16 lb. treatment, N. Y., per sq.yd., f.o.b.	2.50
Paving brick 3½x8½x4, N. Y., per 1,000 in carload lots, f.o.b.	50.00
Paving brick 3x8½x4, N. Y., per 1,000 in carload lots, f.o.b.	45.00
Crushed stone, ¾-in., carload lots, N. Y., per cu.yd., delivered	3.40
Cement, Chicago, in carload lots, without bags, f.o.b.	1.95
Gravel, ¼-in., cu.yd., delivered New York	3.40
Sand, cu.yd., delivered New York	2.15

Old Metals—New York and Chicago

Heavy copper, cents per lb.	8.75
Light copper, cents per lb.	7.75
Heavy yellow brass, cents per lb.	5.75
Zinc, old scrap, cents per lb.	2.25
Lead, cents per lb. (heavy)	4.25
Steel car axles, Chicago, net ton	$15.25
Cast iron car wheels, Chicago, gross ton	13.75
Rails (short), Chicago, gross ton	14.00
Rails (relaying), Chicago, gross ton (65 lb. and heavier)	28.50
Machine turnings, Chicago, gross ton	6.25

American Turnstiles for Argentine Subway

Perey Manufacturing Company has received an order for more than one hundred Perey Coinpassers and a number of Perey Standard Passimeters for installation in the stations of the new Lacroze subway in Buenos Aires, Argentina. The system of collection will be similar to that used on the B.-M.T. subways in New York. The fare to be charged is ten centavos and the coinpassers are being made to receive a coin of this denomination. The instruments are to be provided with bulls-eye illuminated coin detectors to prevent the deposit of slugs and counterfeit coins.

Brill Company Reports Orders

The J. G. Brill Company announces that it has recently received orders for three double-end, double-truck cars, to be equipped with Brill 84-E trucks, from York Railways, York, Pa. Eighteen double-end, double-truck cars, to be provided with Brill 177-E type trucks, have been ordered by Empresas Electricas Associadas, of Lima, Peru. The Brill Company will also supply eight 40-passenger trolley buses for the Chicago Surface Lines.

Equipment Ordered for Reading Railroad's Substations

Another step in the $20,000,000 electrification program of Reading is reflected in an order to the Westinghouse company for supervisory control and switchboard equipment for seven power substations and fourteen intermediate stations to supply current to the electrified zone. There will be a total of 24 controlled stations in the present electrification project.

Power will be received from the 60-cycle commercial lines of Philadelphia Electric Company, at the Wayne Junction converter station, and distributed at 25 cycles to substations as required for operation of trains. The electrical energy will be under immediate supervision of chief power dispatcher at Wayne Junction, and any rearrangement of the power feed, necessitated by failure or repair to lines, may be made without interruption of service.

Ohmer Directors Meet

At the meeting of the board of directors of the Ohmer Fare Register Company, Robert C. Lee of the Guardian Trust Company, Cleveland, was elected a director to fill a vacancy on the board. Other directors are John F. Ohmer, H. B. Ohmer, John P. Breen, John S. McIntire and H. W. Baker, of Dayton; Freeman C. Allen of Rochester, N. Y.; F. J. Lisman of New York City and John F. Ohmer of Los Angeles.

During the meeting at the company's offices, several new machines that will shortly be announced to the public, were inspected and plans approved for their distribution.

Copper Lowest in Twenty Years

With sales of copper in considerable quantity at 10.75 cents during the past few weeks, this commodity has attained its lowest price in the current market, as well as the lowest level in more than twenty years. The decline started shortly after the first of the year, when the price was cut 4 cents a pound from the 18-cent level, where it had been pegged for several months. In spite of efforts on the part of producers to maintain the price at a higher level, there has been a steady decline to the present low figure. Heavy stocks of the metal on hand and a decreased demand on the part of certain interests, which have been large consumers, have contributed to lower the price. A sharp curtailment of output is now forecast, with a probable gradual upswing in the quotation.

Production to Start by General Car & Coach Company

O. F. Warhus, president of the General Car & Coach Corporation, has announced that production of the company's standardized street car and trolley bus will start on a schedule of 100 cars a year at the factory established in Rensselaer, a suburb of Albany, the plant representing an investment of $175,000. It is intended to start manufacture within a few weeks, and within three months it is expected that 150 men will be at work. This number will be increased to 200 when production begins to hit the stride now planned.

The type of car proposed for manufacture will be similar to Car No. 301 of the United Traction Company, Albany, to be built under patents held by Mr. Warhus. The vehicle will weigh 12 tons.

The site acquired by the new company for its plant was formerly owned by the Eastern New York Utility Company. It includes a carhouse, freight shed, power plant, machine shop, garage and offices and contains approximately 45,000 sq.ft. of floor space. The property covers 5 acres in the heart of lower Rensselaer.

Mr. Warhus is a native of Davenport, Iowa. He has had twenty years of experience in the field of electric transportation. He was vice-president and general manager of the Versare Corporation and later vice-president and director of the Cincinnati Car Company, where he was in charge of engineering and sales.

T. M. van der Stempel, formerly of the staff of ELECTRIC RAILWAY JOURNAL, and a graduate mechanical-electrical engineer, will be in charge of sales. He has had experience both here and abroad in electric railway and highway transportation engineering problems.

✦

Firestone Tire & Rubber Company, Akron, Ohio, has prepared figures showing the sharp decline in tire-mile costs over a period of years, indicating the engineering and manufacturing progress made in this field. According to the company's reckoning the average tire-mile cost of its product for 1930 is approximately one-fifteenth of the cost in 1910.

✦

White Motor Company, through its directors, at a meeting held on Aug. 1, reported net earnings for the first six months of the current year of $1,048,000, as compared with earnings of $1,404,000 for the same period last year. Sales during the period exceeded $21,000,000, which is approximately 90 per cent of the peak period of last year. The showing is regarded as particularly gratifying in view of general business conditions. Through a readjustment of working schedules and rearrangement of hours, the company has maintained its full working force in the production department of the business, and there have been no reductions in the wage rates of any of the workers.

Conditions Favorable Now for Modernization

TO UNDERTAKE extensive plant improvement at a time like the present, when business conditions are considerably below normal, might at first appear to be the application of a counsel of perfection, but actually there are excellent reasons for so doing. The general feeling existing among business men that expenditures of all kinds should be curtailed until conditions improve, appears to be founded upon vague apprehension rather than definite facts. In many respects the immediate future presents an unusually promising opportunity for modernizing equipment and machinery.

For some time past the barometer of business has stood without much change at about 85 per cent of normal. This closely approximates the minimum figure recorded during the 1921 depression. Past experience indicates that stiff resistance begins to be felt at about this point, and it appears improbable that any further serious decline will now occur, although a definite upward movement may not set in immediately.

PRICES are now the lowest in years. Economists who have studied the matter state that they are not likely to go lower. On account of its feeling of apprehension, business has not been borrowing extensively and idle money has been accumulating. This has resulted in the creation of a favorable credit situation which makes the forward buying of raw materials at this time a thoroughly sound policy. There are signs that shrewd management in many lines has already begun to buy. Stocks of commodities and raw materials have been allowed to run extremely low. If buying becomes general the situation may change with the suddenness of the bursting of an ice jam and a lively scramble for materials may ensue.

Not only is the present a favorable time for buying ordinary materials and supplies, but it is also a particularly opportune time to undertake modernization of plant and equipment. This is no less true for the electric railways than for other industries. The future undoubtedly will make exacting demands upon the transportation companies as to quantity and quality of service. Any idea that standards of living will be permanently lower and that former automobile users will be compelled to patronize the public transportation service is likely to prove an illusion. The history of business depressions in the past shows that standards of living are not permanently affected. Electric railways cannot afford to postpone improving their equipment in the hope that the public will remain satisfied with what they now have. The railways must continue to improve their product to keep pace with public demand.

ANOTHER factor of supreme importance is the economic advantage of modernization of plant and equipment. It has been demonstrated again and again that new rolling stock can be made to pay for itself out of the larger earnings and the operating savings. This is equally true of other improvements. Shop costs can be substantially lowered by the introduction of up-to-date machinery. Track and line maintenance costs can be reduced through modernization.

Under existing conditions the financing of improvements should not present any very serious problems. The electric railways have been less affected than any other industries by the present business depression. Credit is comparatively easy. The bankers will scarcely remain deaf when it appears that the work to be carried out will be quickly paid for by the resultant savings. A dollar spent today for modernization will buy substantially more that it has for some time past, and more than it is likely to do in the future.

Timidity a Bar to Progress in Car Design

EXPERIMENTAL designs of cars incorporating radical innovations have been comparatively numerous during the past few years. These developments have been received by the industry with lively interest. But only in a few instances have railways actually bought such cars and tried them out on an extended scale. When purchases have been made it has been customary to order cars designed very much along traditional lines.

In defense of this policy it is contended that the new developments have not yet been proved out in service and that their adoption on a large scale would involve grave risks. There is some truth in this contention, but it should be remembered that there is also a certain amount of risk in not buying equipment of the latest design. New cars bought today but built along the same general lines as the cars of a decade ago, may be rendered obsolete almost at the outset if the latest designs prove successful.

The fear that equipment of new design will not stand up in service has been exaggerated beyond all reason in the electric railway industry. No such apprehension exists in other fields. When Henry Ford brought out his new model automobile a few years ago, prospective purchasers did not question its practicability and continue to buy the old Model T. They bought the new machines as fast as the factory could produce them.

The latest types of electric railway equipment are the outgrowth of painstaking scientific study. That they will give faultless service is too much to expect. On the other hand, there is no reason to anticipate that they will prove less satisfactory than the older types. In fact, there is every reason to expect that they will prove more satisfactory. So long as the railways refuse to adopt these new designs and cling tenaciously to the designs of a decade or more ago, they must expect to have their equipment appear obsolete.

Neglect of Precautions Against Fire May Prove Costly

INDUSTRY pays the cost of fire insurance. From that fundamental principle there is no escape. This means that a favorable record maintained over a period of years will make possible lower rates; conversely, a succession of disastrous losses will just as surely produce higher rates.

As a result of the improved record of the electric railways of the country for some years past, the insurance committee of the American Electric Railway Association, through co-operation with representatives of the stock fire insurance companies, was able in 1929 to secure a substantial reduction in the cost of insurance to the industry, resulting in an aggregate saving of many thousands of dollars in insurance premiums. Within the past year, however, there has been a change in the trend. Carhouse fires resulting in losses in excess of a million and a quarter dollars have been reported.

Investigation into the causes of some of these recent fires would suggest that adequate precautions have not been taken. In one instance, where a large loss was sustained, there was a delay of fifteen minutes between the discovery of the blaze and the turning in of the alarm. The employee who discovered the fire ran past one alarm box, the location of which should have been familiar to him, to another box located a quarter of a mile away. The presence of dry grass in car storage yards has been responsible for a number of dangerous blazes. Certainly this would appear to be an inexcusable neglect of ordinary precautions. On one particular property more than 40 fires occurred in the switch groups of cars in service. Lax inspection seems to be the only possible explanation of this situation.

If, in a spirit of economy, there had been a tendency to reduce expenditures for fire prevention below a safe margin, it is much to be regretted. In the long run it will certainly prove to be very poor economy. While the routine of fire prevention is not a particularly inspiring job for those who carry out its details, it is a most important one. If it is neglected, the entire industry will pay heavily.

Investment by Compulsion

UNREASONABLE in the extreme is the attitude of some municipal authorities in requiring the electric railways to make non-productive investments. An excellent example of this is furnished by the experience of an electric railway company which owned a combination railway-highway toll bridge. In response to a widespread popular demand that this be made a free bridge, the company presented it without charge to the municipality, stipulating only that its cars should always have free use of the bridge. But the number of automobiles using this bridge increased rapidly, and the municipality soon decided that the old bridge should be replaced by a larger and more pretentious structure. This was done at no inconsiderable expense and the railway was presented with a bill for something more than $100,000 as its share of the cost of building a bridge which served its purposes no better than the bridge which it had once owned and given away.

Not altogether unlike this, is the situation in another city where it is proposed to create an impressive plaza adjacent to a handsome new steam railroad passenger station. Numerous street changes are contemplated in this project. Near by is a power house owned by the local electric railway, and under the streets are many cables running to outlying substations. Relocation of conduits and cables will probably cost nearly $100,000. Does the city expect to pay the cost of this phase of its civic improvement program? Certainly not—the brunt of the cost is to be borne by the company, which is perfectly satisfied with the present location of its conduits and cables.

Another similar instance is found in a plan for extending the municipal park system in a certain city, involving the relocation of street railway tracks at an estimated cost of about $500,000 to the company. In return for this the railway gets exactly nothing—no more passengers, no more revenue, no reduction in operating expense.

Now, it so happens that in the cities where these companies operate there is great hue and cry about the high cost of street railway service. Officials of the local government are loud in their assertions that the companies' figures of capital invested are far too high—that these investments do not truly represent property "used and useful in the public service." These officials are ardent advocates of the prudent investment theory of valuation. But they are strangely silent about the prudence of a railway making an investment of $100,000 in a new bridge for private autos, or a similar sum in

Digitized by Google

new cables and conduit to permit the creation of an impressive plaza at the gateway to the city, or $500,000 in track changes necessitated by the extension of the municipal park system. Such expenditures, into which the railways are forced without hope of ever getting back one single penny in return, would be severely criticized if they were done voluntarily. Because they are done under compulsion does not make the expenditure any more justifiable. It merely shifts the blame to the municipal authorities.

Seattle's Ever-Present Problem

TURMOIL and trouble have been the lot of the city of Seattle ever since it took over the railway lines of the Puget Sound Power & Light Company shortly after the war. The prediction was made at the time that difficulties would ensue, but there was no stopping the politicians then in the saddle. They have now passed into oblivion, but what a heritage they have left to their successors! At Seattle mayors have come and mayors have gone, as have councilmen, too, while the Seattle Municipal Railway has proceeded from bad to worse, physically and financially. In the post-war period, the privately owned railway systems have certainly had their troubles, but no patient on the sick list suffering from complications incident to recent economic changes is nearer financial death than the Seattle Municipal Railway.

Ole Hanson, Seattle's Mayor who put the city into the railway business, is merely a memory. But municipal ownership in that city is more than a memory. It is a very unpleasant reality. To review all the details is not necessary. Although a moratorium on the principal of the debt has been arranged for a period of two years to give the municipal railway a breathing spell, the situation is so bad that resort has again been had to warrants payable in the future to provide cash to meet the current interest charges. In effect, Seattle has been robbing Peter to pay Paul. The city has at times borrowed from the light fund to meet railway obligations. It has been constantly living out of capital. It has gone from one unhappy expedient to another. Each has failed except as a temporary measure. Even the grandiose plan went askew involving the marketing of $10,000,000 of general city obligation bonds, $9,000,000 to be applied to the liquidation of original purchase price and the rest to go for improvements. The present mayor was right in saying that "a straight out-and-out railway bond issue would not be attractive to investors under present conditions in Seattle." Thus, as one commentator has said, Seattle's experiment in running its railway seems to be entering its last disastrous phase.

Of course, high-grade managerial talent might help the situation, but men of real capacity are few and far between who would risk their reputations under the system that endures in Seattle. What is the answer? Seattle got nowhere on a 5-cent fare. It has got nowhere on a 10-cent cash fare with three tickets for 25 cents. The existing situation presents an economic problem of the first magnitude. As such it must be solved. Politics has not found the answer in the past fifteen years. Will the committee of citizens now charged with the work of planning a remedy have the gumption to suggest the one answer that might contain a ray of hope —to divorce the operation of the system from politics? That would be a strange anomaly—municipalization without politics.

Dropping the Trailer

CONSIDERED to be an economical means of increasing passenger carrying capacity on heavy traffic routes, the operation of multiple-unit and trailer trains enjoyed marked popularity during the first half of the past decade. As congestion on the streets became worse and peak loads became heavier, more and more trailers were pressed into service. Almost every large city railway used trailers, some on an extensive scale. But conditions have changed during the past few years, and a number of companies are reverting to single car operation. The move made recently by the Chicago Surface Lines in abandoning all of its trailer operation is particularly significant. Shortly after this came news that the Cleveland Railway, another large user of trailers, was suspending their operation on the Lorain Avenue line to study the results with single units.

In both cities the trailers were dropped so that more frequent service could be given and faster schedules maintained. Since speed and frequency are important factors in encouraging the public to patronize street cars, the companies feel that this move should result in increased riding. Use of single units may actually decrease the cost of operation, and if riding is stimulated the additional gross income and net income may be quite pleasing.

Speaking generally, trains operated in city service have been of three types: (1) motor car and unmotorized trailer; (2) motor car, and trailer with motors but without control; (3) multiple-unit cars. In most cities the practice has been to operate the motor car as a single unit in the slack hours and pick up the trailer for the rush. This has the advantage of increased rush-hour carrying capacity without a corresponding increase in platform labor. On the other hand, picking up and dropping trailers is a cumbersome job unless special facilities are provided. Moreover, to haul a trailer at the desired speed, the motor car must be equipped with large capacity motors making it overpowered for operation as a single unit.

Permanently coupled trains have been used to some extent, and recently a considerable number of articulated units have been placed in service. But operation of these large units throughout the day can be justified only on lines where riding is exceptionally heavy. A serious disadvantage of all types of train operation is that it is ordinarily slower than single-car operation because of the greater number of stops which each unit must make.

Weighing the cost of operation against the resulting patronage is the only way to determine which type of service is the most satisfactory. Analyses of this kind seem to indicate that on some properties train operation is more satisfactory than single units. On other properties it appears that single units are the better choice. In Chicago, the frequency of service was doubled and the running time reduced 12 per cent on Madison Street when trailer operation was abandoned. These are important improvements, and their effect in making the service attractive deserves serious consideration. Similar improvements are anticipated as a result of the change in Cleveland. Whether or not the theory on which these companies are working has a wider application is difficult to foretell. Certainly, the comparative results of single units and trailer operation in both Chicago and Cleveland will be observed with keen interest by the entire electric railway industry.

Cincinnati & Lake Erie's

NEW DE LUXE CARS

Challenge the Steam

WHAT is perhaps the most interesting and significant experiment of recent years in the development of interurban passenger traffic appears to be a pronounced success. This experiment, which has been tried on the lines of the Cincinnati & Lake Erie Railroad in Ohio, seems to point the way for the upbuilding of the passenger business of many interurban properties whose physical characteristics are such that sustained high speeds can safely and comfortably be made.

Early in 1929 the management of this interurban, under the leadership of its president, Dr. Thomas Conway, Jr., began a series of experiments designed to point the way to the evolution of an interurban car much faster and more comfortable than any which had theretofore been built. To this end the company adapted some of its low-level trucks to permit of unusually high speed and mounted them under car bodies generally similar in appearance and size to those which the management had in mind. These experiments were conducted in conjunction with the Westinghouse Electric & Manufacturing Company, the General Electric Company, the J. G. Brill Company, the Cincinnati Car Corporation, and the Westinghouse Traction Brake Company. Many valuable lessons were learned; many baffling problems were encountered and, one by one, they were solved. Specifications embodying these developments were thus gradually built up under the active supervision and direction of W. L. Butler, executive vice-president of the railway, who, more than any other man, is responsible for this unusual contribution to the car builders' art.

In these experiments certain premises of the management were clearly established:

1. That it was possible to build a car of aluminum and steel which, while light in weight, would possess the necessary staunchness and rigidity for sustained speeds on level tangent track in excess of 75 m.p.h. and also have satisfactory riding qualities.
2. That it was possible to obtain these results with a low-level truck, using 28-in. wheels, provided the adaptations and changes worked out during these experiments were made in the truck design to withstand the extreme stresses and to absorb and cushion the magnified road shocks, side sway and other forces incident to such high speeds.
3. That, all things being equal, a car of the low-level type would ride much better at high speeds than the conventional interurban car.
4. That the attainment of such speeds was conditioned upon the evolution of motors which would meet the truck clearance limits and possess the power necessary.
5. That with such high speeds one of the most serious problems was braking, and that methods of braking additional to air brakes must be employed. The new cars are equipped with both air and magnetic brakes, interconnected so that the latter come into use only after the air-brake application approaches the safe limits of wheel friction.
6. That to attain great speed the lines of the car itself were important. The roof must be as low as possible consistent

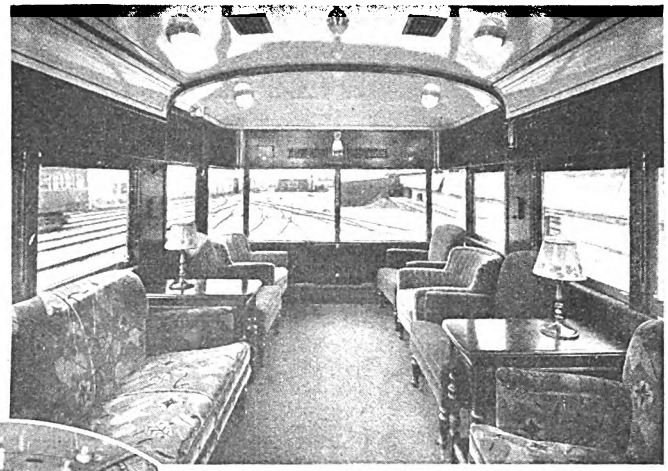
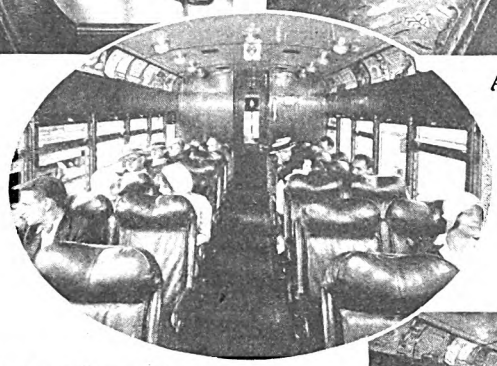
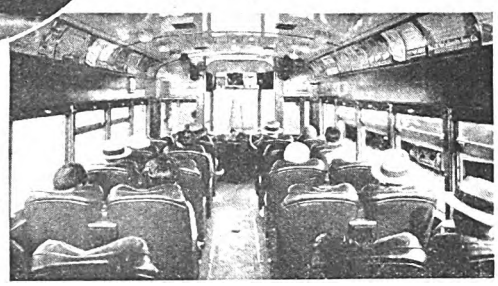
Luxurious fittings are used in the observation-lounge compartment



An unobstructed view is obtained from the rear of the observation compartment



Comfortable seats are used in the coach, and the entire front end of the car has been opened up so that passengers may look ahead



Revolutionary and luxurious equipment attaining speeds in excess of 80 miles per hour permits a brand-new type of long-distance passenger service. Rapid increase of business is being made without undermining existing traffic

Railroad and the Bus

with proper ventilation and interior appearance, and the lines of the car such that it would not tend to "float" at high speeds. The car should be streamlined, and the roof lines should be so designed as to increase the traction at high speed.

Clear Vision Front Deemed Essential

From interviews by the company's traffic supervisors and checkers with hundreds of passengers, both on its own rail and bus lines and those of competitive steam railroads and interstate bus lines, the management became convinced that one of the major objections of the traveling public to the interurban car in favor of the bus was that the bus passenger's view was unobstructed; he could see where he was going and enjoy the scenery in front as well as on either side. This greatly increased his interest and enhanced the attractiveness of the journey. While it was recognized that electric railway operators were reluctant to have the front ends of their cars "opened up" because of the danger of flying glass in collisions, the management determined to adopt the characteristics of the bus and of the limousine and by placing shatter-proof glass in all front and rear sash of the car, reduce or eliminate this hazard. Moreover a metal bulkhead with shatter-proof glass between the front corner posts of the car at the rear of the platform, forms, as it were, a second line of defense to the passengers in the event of a collision.

Interesting and serious construction problems were presented in thus opening up the front of an interurban car designed to operate at unusually high speeds. Unusual aerostatic pressure would be encountered. The problem of making a car airtight in severe weather must be solved. Because the rear was to be arranged like a steam railroad observation car, it was necessary that all passengers should enter and leave, except in emergency, through the front door. With the future possibility of operating in the Cincinnati subway, it was decided, rather than to have the door extend to the bottom of the lower step, to use a short door and a hatch, mechanically operated and weather and wind proof.

The primary problem was the development of motors within the clearance limits with power to attain the desired free running speed of at least 75 m.p.h. After prolonged negotiations, both General Electric and Westinghouse contracted to construct such motors.

One-half of C. & L. E.'s new interurban cars are the de luxe observation-lounge type; the remainder are coaches. In neither is provision made to carry dispatch freight or trunks—the management being convinced that passengers will not tolerate delays to load merchandise or heavy baggage. Trunks and dispatch freight are handled on certain local runs at times of light traffic, where the type of car purchased in 1927 is operated. In their general features the new coach and the de luxe car are

Totals	47,800 lb.	48,300 lb.

identical except that the space set apart as an observation-lounge in the de luxe type is fitted with transverse seats in the coaches and no luggage compartment is provided in the coach, a small space being reserved for this purpose behind the rear seats.

The railway has had in force about a year a successful profit and savings sharing plan by which its employees participate in the fruits of economies and increased profits. When the time came to formulate definite plans for the operation of the new equipment and the inauguration of the new long-distance high-speed service, President Conway submitted to the trainmen a proposal that all passenger service on the Columbus and Toledo divisions should be operated by one man and that all de luxe service on the system should be so operated. After thorough consideration the men voted to adopt the plan. One-man operation of this service has been entirely successful; both men and management are enthusiastic concerning it. An interesting feature was that, through the introduction of the blue ribbon long-distance service, enough additional car-hours were run to provide employment for all trainmen. Thus it has been possible to give a largely augmented service with a relatively low increase in operating expenses.

The salient features of the specifications of the new cars are summarized in Table I.

The first impression gained is that the car is very low. Its riding qualities, unusual even in a car for ordinary speeds, are due to its low center of gravity, made possible by the use of a low-level type of truck, the absence of high bolsters and the low roof. The taper of the ends to cut down wind resistance is clearly apparent, as is also an adherence to recent notable tendencies in automobile design such as high body sides, or a relatively high window sill. By thus bringing up the window ledge the problem of keeping the car comfortable at high speeds in severe winter weather is minimized. Drafts when the windows are raised in the summer also are reduced. It is, moreover, possible to raise the window sash sufficiently to avoid interference with vision. The relatively high side sheathing and wide letterboards give the car an appearance of solidity and permit a maximum of diagonal and lateral bracing. Concealed lights on the front dash, standard on earlier C.&L.E. equipment, were retained, as were the lamps at the four corners of the car, which the company has found greatly decreases automobile collisions in city streets. Space is provided on the front dash to carry signs for company advertising. Because of the speeds attained, a special locking device had to be devised to prevent these signs from being blown off. A double Hunter illuminated sign shows the destination of the train in white and its name in red letters, a black background being used for both. Attractive train emblems, similar to those on the crack steam railroad trains, are carried on the rear of all de luxe cars. The names of these trains were selected from some 1,211 submitted by employees and their families in a cash prize contest inaugurated by the company. The art work in connection with the train emblems was executed by the Geyer Company, advertising agent of the railway. Upon the inaugural trip of each of these trains, the respective prize winners and their families were the guests of the management. This tangible recognition of the part which the employees played was featured in the local newspapers as a "human interest" story.

Digitized by Google

toilet and luggage compartment, 14 ft., or approximately 37 per cent, are contained in an observation-lounge section in the rear. This section is furnished attractively with large, comfortable lounge chairs and couches upholstered in mohair and small reading tables, carrying attractive reading lamps, spaced at convenient intervals. A Wilton carpet covers the floor. The forward section of the car is equipped as a coach.

In the design of seats for these coaches, the plan originally worked out by the Conway interests for the Chicago, Aurora & Elgin was adhered to. Care was taken to make sure that the seats were low enough to be comfortable for the short-legged passenger. Seat centers were spaced at 33 in. to give plenty of leg room. After much experimentation the proper construction of seat cushions and back cushions was determined to give comfort without excessive springiness, tending to intensify road vibrations. A type of headroll was chosen which would invite relaxation but not be so bulky as to strike the hat. The seats are finished in genuine green leather. They are 39½ in. wide and designed to "fit the back."

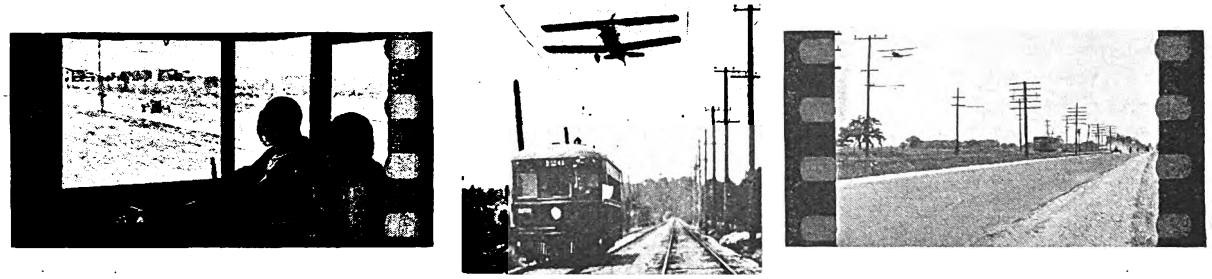
Believing that the operator should be as comfortable as the passenger, equal care was given to the design of his seat. Sample seats embodying varying characteristics were constructed by the Hale & Kilburn Company and shipped to the plant of the Cincinnati Car Corporation, which received the contract for the construction of the cars in accordance with the plans and specifications of the company. These seats were set up in a dummy front end, or platform, in which was located the controller, air-brake valves and other apparatus to be placed on the operating board of the car. The trainmen's cooperative committee then journeyed to Cincinatti, and after explanation of the features of the operator's board, made a careful study of the arrangement from the standpoint of the trainman. The outcome was an entire rearrangement of the operator's board. All apparatus on the front end of the car is inclosed, avoiding unsightly piping, wiring, etc., and improving the appearance of the car. In accordance with the practice on its Cincinnati division, the National cash register is used to record fares.

The new car is equipped with the most modern type of toilet, and the latest sanitary standards have been observed in providing iced water for passengers. Another special feature of the de luxe car is a luggage compartment, situated opposite the toilet.

Remarkable Acceleration and Speed Shown in Tests

In the official tests of these cars, conducted by the railway and representatives of Westinghouse and General Electric, respectively, recently concluded, results were obtained that exceeded all expectations. These are summarized in Table II.

No interurban car has ever equalled the speed developed by this new equipment. Many miles have been "clocked" by competent and experienced observers in which the new cars ran better than 90 m.p.h. The particularly remarkable thing about these cars is that at such high speeds their riding qualities are better than those encountered upon many Class 1 steam railroad observation cars on crack trains. There is a reassuring absence of side sway, tremor or vibration. The passenger enjoys the exhilaration of air flight, where no air pockets are encountered, but without its noise and vibration. In the earlier days of operation, many men who thought they had fast automobiles tried their luck in racing these fliers. They were soon left far behind. Certain of the de luxe trains overtake and pass such steam trains as the "Ohio State Limited" to the great amusement and gratification of the interurban's passengers.



The fast trains broke into the movies by winning races against an automobile and an airplane

The Cincinnati & Lake Erie Railroad, like the typical interurban, runs on city streets in several places. The high speed of its equipment is not required for city service, but it enables the cars to make up for time lost in necessarily slow operation on these streets and to land the passenger at his destination in such good time as to induce him to use the interurban in preference to the steam railroad or his own automobile.

Illustrating the advantages of speed, on the Toledo division, the average schedule speed of the de luxe runs on private right-of-way, i.e., excluding city streets, is 46.25 m.p.h. The average schedule speed under such conditions on the Columbus division is 54.1 m.p.h. In other words, this new equipment, like the fleet automobile, when on city streets can observe traffic regulations and the requirements of safety, but make the required schedule by sustained high speed in open country.

"We're in the Movies Now"

The Cincinnati & Lake Erie achieved the goal of all publicity men by breaking into the movies when *Pathé News Weekly* made a sound film record of the staged race between one of its flyers and an airplane. This footage was incorporated in a regular *News Weekly* which has been shown to millions of people all over the

Table II—Results of Speed and Acceleration Tests on the New C. & L. E. Cars

Each of the blue ribbon trains was given a name in a competition among employees.

United States since Juy 12. Incidentally, the company's executive officers have had many letters of inquiry from interested electric railway officers who have seen this movie in their neighborhood theaters.

Emulating Pathé's example, the Mayfield Photo Service, which produces movie film of interesting events for local theaters, requested permission to arrange a speed contest between a special racing automobile and one of the flyers. It was decided to hold this race between Springfield and Columbus where the National Pike parallels the railway private right-of-way. In order to insure the safety of the automobile, motorcycle police escorts were provided to clear the road. The race was photographed from the interurban car, from an airplane and from fixed locations along the road. The film tells an exciting story. The automobile beat the interurban on the getaway and the succeeding footage shows the tremendous speed which both attained. The motorcycle police found it impossible to hold the pace and gradually fell behind, but fortunately the road at the time was reasonably free of traffic. The racing car tore on, but little by little the interurban forged ahead; when the race was over the automobile was fifteen lengths in the rear.

The large movie houses in Ohio were quick to see the sporting aspects of these thrilling contests. The State Theater in Dayton featured it during the week beginning Aug. 9. At the theater's request, the railway made arrangements to run "The Red Comet" over the city tracks in Dayton. The car was covered with banners on either side, announcing the moving picture feature and was equipped with a radio-phonographic reproducing device to attract the attention of passers-by. An unusually large attendance at the State Theater during the week was reported. Other large moving picture houses throughout the C.&L.E. territory have run a similar film.

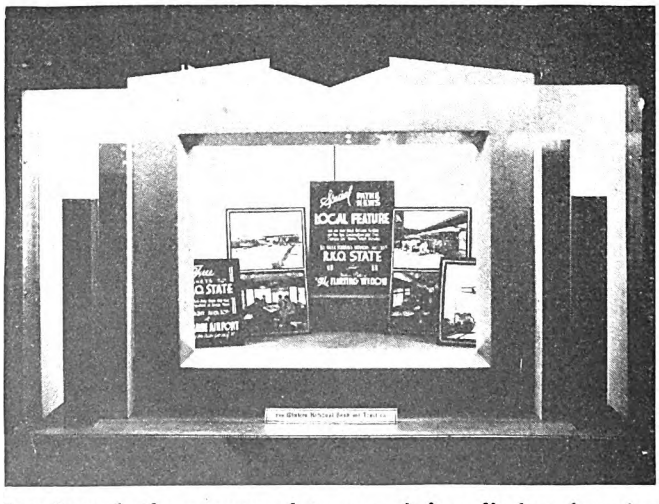
The management is convinced that this moving picture publicity is the most valuable advertising which the new service has secured. It dramatized, as nothing else could have done, the epochal character of the new innovation in transportation. It aroused the sporting instincts of many thousands of people; it created the desire to ride upon this new service. Above all, it carried to thousands of motorists the lesson that, from this time forth, the automobile driver should exercise extreme caution in crossing the tracks.

Prior to the inauguration of the new service a vigorous and carefully prepared publicity campaign had been mapped out and was progressively executed. The company's publicity agents furnished news stories to the local press, chronicling in turn the imminence of the completion of the cars, the delivery of the first car, its preliminary trials, the general nature of the changes decided upon, the successive arrival of additional cars, steps taken to train the crews in the new equipment, the work being done by the maintenance-of-way and line departments in preparing the property for the new fast service, and, in general, the revolutionary character of the service contemplated.

In this way, the curiosity and interest of the public and of the newspaper editors were gradually fanned. On Sunday, June 29, the Geyer Company, as the representative of C.&L.E.., was host to some 150 newspaper men and women representing the daily and weekly publications in the various cities and towns served. They were brought to Dayton in the new de luxe observation type cars. At the luncheon explanation was made of the plans for giving publicity to the new service, both through news stories and through paid advertising. Many questions were asked and answered. The guests were returned to their homes in the de luxe equipment. This luncheon greatly quickened the interest of the newspapers in the bold experiment, and gave to their editors first-hand knowledge of the attractiveness and comfort of this new service.

Cars Exhibited in Leading Cities

Between July 15 and 19, a new de luxe type car and a new coach were placed side by side with the old equipment previously used on the I. C.&E. or Lima-Toledo properties, in the public square or other prominent location in Cincinnati, Columbus, Dayton, Toledo, Springfield, Hamilton, Lima, Bellefontaine, Middletown and West Jefferson. This display of the new equipment was currently advertised in the local press. Many thousands of people passed through these cars. Representatives of the company's traffic and operating departments, as well as picked men from among the train crews, were in attendance. In addition to distributing a souvenir booklet picturing the new cars and explaining the high-speed service, these men answered many questions.



Prominent banks co-operated to use window displays featuring the movies of the races won by the new cars

In order to appreciate the significance of the new service made possible with the de luxe equipment, it is necessary to consider briefly the recent

history of the property. The Cincinnati & Lake Erie Railroad, the president of which is Thomas Conway, Jr., came into existence on Jan. 1, 1930, at which time, coincident with taking title to the Indiana, Columbus & Eastern and Lima-Toledo properties, the Cincinnati, Hamilton & Dayton Railway changed its name. These acquisitions gave the consolidated company a through interurban line from the Ohio River, at Cincinnati, to the Great Lakes at Toledo, a distance of 220 miles, as well as a fast east-and-west line connecting Dayton, Springfield and Columbus. The distance from Dayton to Columbus is 72 miles.

Readers of Electric Railway Journal are familiar with the notable success achieved by the Conway interests in the upbuilding of the C.,H.&D. property. These interests acquired this property early in 1926 after a checkered career of receiverships, abandonments and prolonged litigation extending over a period of some nine years. Steps were immediately taken to modernize the property. Interurban trackage was reconstructed in large part and rehabilitated throughout; the power supply was modernized, new automatic substations being constructed and an adequate and reliable source of power provided; a modern car shop was acquired at Moraine, just south of Dayton, at which point the company's offices also were established. Finally, all old equipment was scrapped and new equipment was purchased and put into service. The running time was shortened, schedules were rearranged to give frequent and convenient trains, modern methods of selling service and developing traffic were instituted, and a vigorous publicity policy was inaugurated and steadily prosecuted. In consequence, the C.,H.&D., unlike other interurban carriers of Ohio, in the years from 1926 up to the beginning of the current business depression, not only held its traffic against the inroads of the private automobile, but actually increased its passenger revenues. This unusual achievement attracted the attention of the entire industry.

The most rapidly growing portion of the road's business, however, was the freight traffic. This business was handled almost entirely in conjunction with neighboring interurban lines. After prolonged study, the management finally decided that the investment of substantial sums, year after year, in developing freight business, in the face of the highly uncertain future of the connecting interurban lines reaching the principal traffic centers on Lake Erie, was of doubtful wisdom. Accordingly, the C.,H.&D. acquired title to them. The Conway management believed that in addition to freight it could successfully develop a substantial passenger traffic on the interurban lines north and east of Dayton, which connect large centers and pass through farming country and villages.

Automobile Competition Severe

The railway lines are paralleled throughout by improved concrete highways, the National Pike between Dayton and Columbus and the Dixie Highway between Toledo and Cincinnati. The I.,C.&E. and Lima-Toledo lines in past years have felt the full force of automobile competition, and in earlier years were subjected to motor bus competition. These motor bus lines were acquired by the Conway interests, in conjunction with the interurban properties. At once the motor bus and rail passenger rates were made identical, and tickets interchangeable, making it possible for the passenger to use either the rail or the bus, as he might elect. Motor bus and rail schedules were co-ordinatd.

Prior to the acquisition of the I.,C.&E. and Lima-Toledo lines, the management made a thorough survey of their passenger traffic possibilities. The conclusions were that the possibilities for the development of local traffic, of the type formerly handled on the I.,C.&E. and Lima-Toledo properties, were either non-existent or exceedingly limited. Some additional traffic would doubtless be attracted by new, attractive modern and fast cars, operated in local service. Dr. Conway became convinced that the only promising field involved the creation of a brand new type of service to attract long-distance pas-

The movies were well advertised by running cars covered with banners through the main streets of several cities

sengers between Cincinnati and Toledo, Cincinnati and Columbus, Dayton and Columbus, or Dayton and Toledo, for example—distances ranging from 71 to 220 miles. The development of this business, however, involved getting the roadway into condition to permit of very high-speed operation and evolving a type of interurban car which would embody the comfort and speed which the management believed the public demanded. Early in 1929, prior to taking title to the other properties, an extensive rehabilitation program was inaugurated to permit of high-speed operation. At the same time a new type of flashing light highway crossing signal was evolved by the company's staff and installed at important highway grade crossings on the property.

On Sunday, July 6, the new high-speed through service with observation-lounge car equipment was inaugurated. This consists of three daily limited trains each way between Cincinnati and Toledo, with connections for Detroit; three each way between Cincinnati and Columbus, and two additional de luxe limited trains between Dayton and Columbus. This gives the passenger traveling between Cincinnati and Dayton the choice of six limited trains. The passenger between Dayton and Columbus has the choice of four limited trains; while traffic between Dayton and Springfield is served by seven limited trains in each direction daily. In addition, the local service is retained without change.

New Reduced-Rate Excursion Tickets Introduced

The management is convinced, as a result of its experiments in the past two years, that many interurban railroads have advanced their fares to a point beyond that which will yield the maximum return; certainly this was true on many parts of its own property. The public compares first-class interurban service more closely with bus service than with steam railroad service. An endeavor to charge fares approximating those of a steam railroad drives traffic to any competing buses, or to the private automobile. The company believes that the aim should be to improve the load factor—the proportion of occupied car seats and the number of profitable trains operated daily—and should charge that rate of fare which will produce the maximum operating revenue and the highest load factor.

Coincident with the introduction of the new de luxe service and new equipment in the local service, a system of special tickets was offered at attractive rates, designed to develop business. Prior thereto round-trip tickets cost twice the one-way rate, but under the new plan five-day round-trip tickets between important centers are sold at substantial reductions. Week-end excursion tickets also were instituted. A comparison of rates before and after July 6 between typical important stations is given in Table III.

No extra fare is charged for the de luxe service, either in the coach portions of the car or in the observation-lounge section. A passenger can ride for the same cost on the de luxe service, the regular local service, or in the company's bus lines, as he may elect; the special tickets above mentioned are accepted on all three.

The existing rates applicable to country stops and small towns or villages were not changed, but with special tickets and rates a successful drive is being made for this type of business.

Some interesting experiments have been made in the stimulation of relatively short-haul interurban traffic. In the summer of 1929 a special one-day round-trip rate of 50 cents was offered between Middletown and Hamilton, a distance of about 12 miles, and a special twelve-ride ticket, good for 30 days, selling for $2.50. Previously the round-trip rate was 80 cents, or double the one-way fare, and no special ticket had been sold. The purpose of these experimental rates was to determine to what extent the workers in factories in either city, residing in the other, could be induced to use the interurban rather than their automobiles. In two months the revenue passengers between these cities increased 97 per cent.

On the Columbus division, about 11 miles east of Dayton, is the village of Osborn, at which are the plants of the Wabash Portland Cement Company and the Southwestern Cement Company. These plants employ a considerable number of workers living in Dayton, and many Osborn residents travel back and forth to Dayton to business and to shop. The one-way fare between Dayton and Osborn was 30 cents and the round-trip 60 cents. The one-way rate remains unchanged, but on July 20

the round-trip rate was reduced to 40 cents. This change was advertised in the local newspapers. A leaflet giving the new rates and the schedule of trains was distributed by employees of the company in a house-to-house canvass. The record in Table IV of ticket sales by weeks since this change was made is most interesting.

Encouraged by the success of these experiments, it is planned to cover in similar fashion a number of other communities of secondary size served.

One of the most impressive features of the de luxe service is the steady increase in its traffic and earnings, week by week. The record is summarized in Table V.

According to the statistical studies of the American Electric Railway Association, the average passenger earnings of 34 interurban lines throughout the country in 1929 averaged $9.29 per passenger car-hour.

The increase of travel from the new service also is clearly seen in a comparison of ticket sales at important stations. Table VI shows substantial gains at Dayton, Columbus and Toledo, ranging from 16 to 46 per cent. The showing at Cincinnati has been more spectacular than at any station on the property, the aggregate ticket sales in August being 662 per cent in excess of the June business. The most significant feature of this record is that it has been created in a period of intense depression, when industrial employment and general business conditions were tending downward.

Newspaper representatives from cities in the C. & L. E. territory were brought to Dayton and entertained at a banquet by the company's advertising agents

Earnings of the Local Rail Service Hold Up

The blue ribbon trains make no stops in the rural districts or in the smaller villages and make only a limited number of stops in the larger cities and towns. In the rural districts the de luxe service is not competitive with the local service, which was continued without change. It does offer competition, however, for traffic between the larger communities, which constituted the major portion of the previous business.

The effect of the de luxe service upon the earnings of the local rail service is pictured in Table VII. The astonishing fact disclosed is that, with the exception of the Columbus division, the de luxe service apparently drew no traffic from the locals. The volume of de luxe service operated on the Columbus division between Dayton and Springfield is somewhat greater than on any other division.

Through a subsidiary company the Cincinnati & Lake Erie operates motor bus service paralleling its Columbus division. The de luxe service and the new and more attractive equipment in the local service have diverted about 12 per cent of the traffic from this bus line, although new buses were installed a few weeks prior to the introduction of the new rail cars and no change was made in the bus schedules. The diversion of business is due to the much higher speeds and greater comfort and convenience of the rail service. The scheduled running time from Dayton to Columbus of the local rail service is 40 minutes less than on the bus, while the de luxe service makes the trip in 55 minutes less time than the bus. It was, of course, impossible to speed up the bus service to keep pace with the rail service, both for physical reasons and because of the speed limits stipulated by the Ohio commission and the state law.

A substantial amount of the de luxe business has been diverted from the interstate buses, especially between Cincinnati and Detroit. The scheduled running time of the de luxe service, including the connection from Toledo to Detroit, is 1 hour and 45 minutes less than that of the interstate bus lines. In other words, this epochal experiment seems to show clearly that a fleet, comfortable rail car, embodying de luxe features, to a very large degree will supplant the motor bus in popular favor.

But the most important lesson to be drawn from this experience is that the high-speed blue ribbon service has developed brand new business for the interurban — traffic which theretofore had used neither the local rail service nor the company's bus line. Where this new business comes from cannot accurately be determined. Interviews with passengers on the de luxe trains, however, indicate that it is made up, in the main, of traffic diverted from the steam railroads and from the private automobile. It is perhaps significant that on July 27 the Big Four Railroad withdrew two trains—the east and westbound trips of the "Senator"—between Cincinnati and Columbus. A large part of the de luxe travel has been business which has been stimulated or created through constructive publicity and modern methods of passenger solicitation, much of which would not have moved otherwise.

Interdependence of Industry and Transportation Emphasized

EFFECTIVE publicity and merchandising is being carried on by the United Railways & Electric Company, Baltimore, Md., through its car-rider publication *Trolley News*. To emphasize the interdependence of industry and transportation is the object of a series of articles being presented under the general heading "Arteries of Industry." In each issue of this pamphlet, one of the larger Baltimore industries and its product is described, setting forth its importance in the industrial life of the city and emphasizing the fact that the great majority of employees use the street car lines and that the industry is dependent upon and really owes its development to the transportation service.

The following paragraph, used as a preface to each article in the series, repeatedly drives home the basic thought that:

> Today the strength of American Industry flows through its transportation lines. These brief sketches will aim to tell something about the dependence of Baltimore's great and rapidly growing industries upon public transportation and what is being done to keep pace with this growth.

The industries themselves are appreciative of this publicity and in many cases have asked for additional copies for their employees and customers.

Cost Analyses Indicate Field of the Trolley Bus

By W. J. Clardy
General Engineer
Westinghouse Electric & Manufacturing Company

BECAUSE it permits the economic expansion of the field of street railway business, the trolley bus is a useful tool for increasing transportation revenue. It offers a means of providing service in the smaller cities, serving closely built-up districts that do not quite justify street cars, or extending into new territory in the larger cities with a reasonable investment and low operating cost. Moreover, it saves expensive track reconstruction on lightly traveled railway routes, thus permitting continued service at reasonable cost.

It is interesting to consider the trolley bus from the economic standpoint, in comparison with the street car and gasoline bus under various conditions. An accompanying table gives an analysis of the costs of the three means of transportation for two particular conditions of operation. The figures indicate that the trolley bus is preferable to both the street car and gasoline bus for light traffic routes, but is not as economical as the street car for heavily traveled routes. Obviously, there is a point approaching the operation represented in the heavy traffic table where the trolley bus will serve as economically as the street car. Installations in Chicago, Salt Lake City and Detroit have proved this point to be rather high.

A route which has from light to medium traffic represents the ideal application for the trolley bus. For example, consider a line with a one-way trip of 5 miles, operated with a five-minute rush-hour headway and a ten-minute base headway. The total annual cost of operation, including depreciation, taxes and interest, will be: street cars, $216,000; trolley buses, $169,300, and gasoline buses, $202,500. Thus, there is an annual saving of $46,700 for trolley bus operation in comparison with street cars and $33,200 in comparison with gasoline buses. This, of course, is a specific example based on average operating costs which naturally vary for different sections of the country.

A heavy traffic route presents a different picture. If the travel on the same 5-mile line requires a 40-passenger trolley bus every two minutes it is well to consider the use of street cars. A large capacity car, seating 56 passengers, operating on a three minue rush-hour headway, will provide practically the same number of seats and have a greater margin in rush-hour capacity. The total annual cost of operation, including depreciation, taxes and interest, will be: street cars, $333,700; trolley buses, $395,600, and gasoline buses, $474,000. In this case street cars will effect an annual saving of $61,900 in comparison with trolley buses and $140,300 in comparison with gasoline buses.

From this it is evident that the trolley bus has a very definite field of usefulness. Extensions into new territory, some of which may require street cars after the traffic develops; light traffic trolley lines where track needs reconstruction; well-developed residential districts, and routes with medium to fairly dense traffic represent the most advantageous uses for trolley buses.

Comparative Investment and Operating Costs of the Street Car, Trolley Bus and Gasoline Bus

	Light Traffic Route			Heavy Traffic Route		
Investment Costs	Street Car, 42-Passenger	Trolley Bus, 40-Passenger	Gasoline Bus, 40-Passenger	Street Car, 56-Passenger	Trolley Bus, 40-Passenger	Gasoline Bus, 40-Passenger
Route-miles (double track for street car)	5.00	5.00	5.00	5.00	5.00	5.00
Units required in rush hour and one spare	12	13	15	21	29	32
Cost of each unit	$13,000	$12,500	$10,500	$14,000	$12,500	$10,500

TRAFFIC IMPROVEMENTS

Planned for Kansas City

Greater speed combined with safety is anticipated in recommendations of report to the Chamber of Commerce made by the Erskine Bureau. Extensive use of safety zones and loading platforms, elimination of parking and adoption of a new traffic ordinance are urged

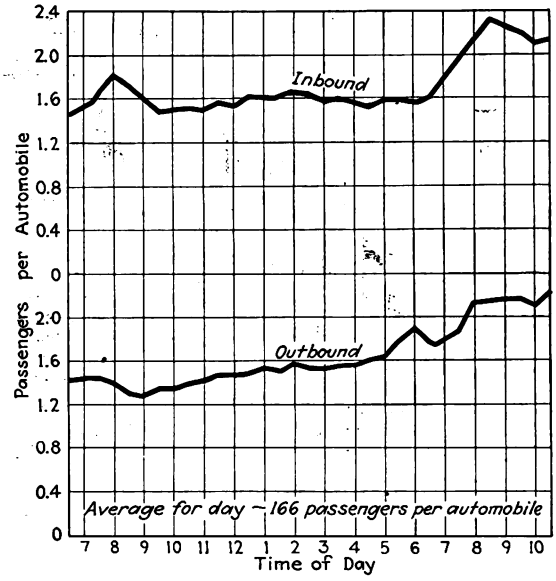
MANY forward-looking recommendations for improvement of traffic conditions in Kansas City are contained in the report of the Albert Russel Erskine Bureau which was prepared for the city-wide traffic committee of Kansas City. The survey was sponsored and the report published by the Chamber of Commerce of Kansas City, of which Conrad H. Mann is president. Preparation of the report, which has required approximately one year, was under the general supervision of Dr. Miller McClintock, director of the Erskine Bureau. This article discusses in brief such of the sections of the report as are of general interest to transportation men.

Design of a balanced and co-ordinated system of traffic control for Kansas City was the primary purpose of the report. The principal specific conclusions and recommendations are contained in a consolidated system of traffic rules and regulation. In the main, the provisions follow along the lines laid out by the National Committee on Street and Highway Safety.

The only legitimate end of traffic control, states the report, is to obtain the maximum convenience and economy of movements consistent with public safety, giving due consideration to the equities of pedestrian, street car and vehicular traffic. Accordingly, all regulations proposed have been carefully weighed with respect to the economic effect, and an attempt has been made to design a system of control which will give a maximum economy in current operations and such improved access as is necessary to provide a stabilization of business site values. In order to spread the traffic load, it is proposed that retail establishments in the central district open at 9:30 a.m. and close at 6 p.m.

Certain special conclusions with respect to safety improvements were considered necessary. It was felt that preventive activities could be amplified during the periods of greatest accident frequency, which are daily from 5 to 6 p.m., weekly on Saturday and Sunday, and in the annual period between August and December, inclusive. It is proposed that an adequate driver's license law should be passed by the State of Missouri in order that drivers' skill and discipline may be increased. Sound driving habits should be encouraged and traffic warning signs be used much more generously than they have in the past.

One of the outstanding features of the report is the plan for parking control. In order to provide an ultimate solution of the intown terminal problem for automobiles, it is concluded that in new buildings special attention should be paid to the incorporation of parking facilities within building lines, or in locations closely adjacent. Business interests should foster the construction of central district garages, further development and utilization of parking lots, and should consider the special advantages to be obtained from the so-called self-contained block.



Passengers per automobile in the central district vary with the direction and time of day

Specific proposals are made for further pedestrian control and protection. Platform safety islands are recommended in the centers of wide streets with heavy vehicular and pedestrian traffic and at street car stops. Temporary minimum protection at such places should be provided by improved button-marked zones. Where such minimum standard temporary zones have been established, the prohibition against vehicles operating to the left of zones at street car stops should be removed.

Attention is given to the improved administration of traffic control planning. It is recommended in the report that there be established in the public works department a traffic engineering office, and that certain specific responsibilities in connection with traffic planning and adjustment be assigned to the director of the public works department.

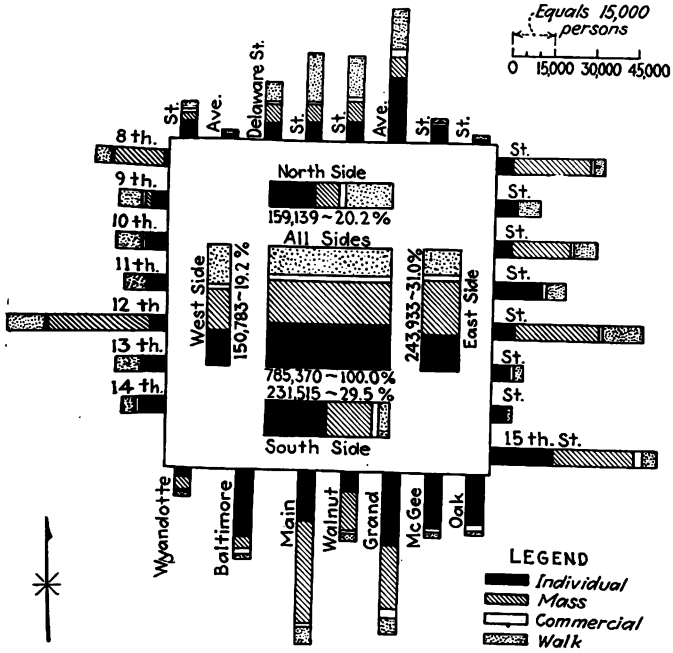
Efforts of the police department to provide adequate and efficient enforcement should receive the firm support of public opinion and of the courts. Better reporting

Digitized by Google

by patrolmen of traffic violations should be required. Courtesy cards or other mechanisms for extending special privileges to individuals or classes should never be used in the future. A reorganization of the traffic bureau in line with the proposed ordinance also is suggested.

Some Provisions of the Ordinance

The proposed traffic ordinance gives specific attention to traffic signs and signals and their display. The director of the public works department should be authorized to designate safety zones where deemed necessary to protect pedestrians and persons boarding and alighting from street cars. The ordinary sections prohibiting a vehicle passing a street car to the left or while a car



Mass transportation vehicles transport 35 per cent of the persons in and out of the central district of Kansas City and automobiles an equal number

is taking on or discharging passengers are included. Street cars are specifically given right-of-way, and vehicle drivers are required to leave the tracks upon signal. Driving of vehicles through safety zones is prohibited, and where vehicles are permitted to drive to the left of the zone they must not unnecessarily interfere with any street car about to stop.

Drastic provisions would prohibit parking at all times on certain designated streets in the central business district, from 7 a.m. to 6 p.m. in other locations, and from 7 to 9 a.m. and 4 :30 to 6 p.m. in still other places. These designated locations cover practically all of the business district.

Through streets are established to a greater extent than ever before and include nearly all of the street car routes. All vehicle drivers entering such through streets are required to make a complete stop before advancing beyond the property line.

Traffic Control of Utmost Importance

Street traffic is one of the most pressing physical problems confronting the community is the conclusion of the report, and the most certain and economical relief is to be found in carefully designed plans based on competent analysis. In conducting the work the committee and the staff were guided by two objectives: first, the maximum protection of citizens from injuries and death from street accidents; and, second, the maintenance of a reasonable facility of movement of all types of traffic in order that the city may obtain the greatest possible convenience of street use and that the commercial development of the community may be according to a pattern which is not distorted by lower accessibility resulting from congestion.

An attempt was made to give due consideration to the requirements and equities of the various classes of street users. Since pedestrian traffic makes up a large part of the total flow, primary attention was given to its requirements. Street car traffic is a second important factor. On this point the report states:

> Street car traffic is another highly important factor in traffic flow. This importance is derived partly from the fact that mass carriers perform a vital and basic service in community transportation and carry a substantial proportion of the personal movements within a city. Their importance is likewise partially derived from the fact that the operating characteristics of rail units differ materially from those of free-wheel traffic, and that due consideration must be given to these characteristics in the design of regulations, both for the purpose of facilitating street car movement and for the purpose of reducing the obstruction offered by street car operation to other types of traffic.

Automobile operation, the third important factor in traffic flow, represents the largest volume of movements, and, in its spectacular development in Kansas City as in other large cities, has tended to concentrate attention upon its special demands.

The purpose of sound traffic control engineering is the design of traffic regulatory methods which will make increases in volume of all types of traffic possible. Proper physical facilities, sound rules and regulations, adequate control mechanisms, correct education of the general public and firm enforcement of the traffic regulations are all necessary to reduce interference between the various classes of street users to a minimum.

Consideration in detail is given of present street traffic conditions in Kansas City. A city-wide study of traffic volume was conducted. In the central area all of the streets were found to be carriers of large volumes of traffic. Street car traffic was likewise studied and charted. Notwithstanding a constant and steady increase in population, it was found that there has been a general and gradual tendency toward a decline in the number of revenue passengers on mass transportation vehicles per annum, and a very substantial decline in the number of rides per inhabitant. This is stated to be on account of the tremendous increase in automobile registration. The report holds that it is entirely possible that the future will show a less rapid increase in the rate of automobile registration, and therefore in automobile use. It is more than likely, therefore, that, with population increments remaining relatively constant, the future will show a tendency toward a less rapid rate of decline in mass carrier transportation, and possibly an actual upturn of the curve.

On the subject of building heights in the central district, it is recognized that the problem of traffic congestion both within the district and along the arteries leading to it has reached a point of acuteness at the present time. With the development of larger-capacity structures in the central district in the future, these traffic and transportation demands will be materially increased. It is important, therefore, that control planning and the planning of physical facilities for the city be undertaken concurrently with the developments of these greater demands.

Digitized by Google

Methods used by individuals for reaching and leaving the central district were determined by making a cordon count along the lines of Eighth Street, Oak Street, Fifteenth Street and Wyandotte Street. A check was made of all persons entering and leaving by each street and by each means of transportation. From the cordon count it was possible to analyze the modes of transportation used and the proportion of the total flow carried by each agency.

Passenger automobiles accounted for 35.56 per cent of the total traffic, while the street car was next in importance, carrying 33.45 per cent. The proportion of walkers was unusually large, amounting to 23.67 per cent. This is held to be because of the proximity of densely inhabited residential areas. The total of the remaining movements is relatively light.

The number of passengers per automobile was found to run between 1.2 and 1.8, averaging slightly higher than in other communities, in which the average number of passengers per car ranges about 1.5.

From a comparison of the number of vehicles and the number of persons entering and leaving the business district it was found that, while the automobile carried 35 per cent of the number of people, it accounted for 78 per cent of the total vehicular movements. On the other hand, while the street car carried 33 per cent of the passenger movements in and out of the district it only contributed 4.98 per cent of the total vehicular movements. Street cars as well as the other mass carriers, including buses, are revealed as relatively economical users of street space, without consideration of their special operating requirements and characteristics. "It is obvious," states the report, "that the great problem of traffic control with respect to convenience and congestion must of necessity be centered upon a proper regulation of the activities of motor vehicles, inasmuch as these compose 78 per cent of the total number of units entering and leaving the central business district."

Two interesting charts in the report are those of the number of persons entering the business district and the number of vehicles. The comparison indicates on all of the important streets the predominance of automobile traffic in numbers of vehicles. Especial attention is called to Grand Avenue, which carries substantially the largest number of automobiles into and out of the district. The actual number of street cars using Grand Avenue is comparatively small, although more than half of the persons entering the district on this street do so by means of mass carriers.

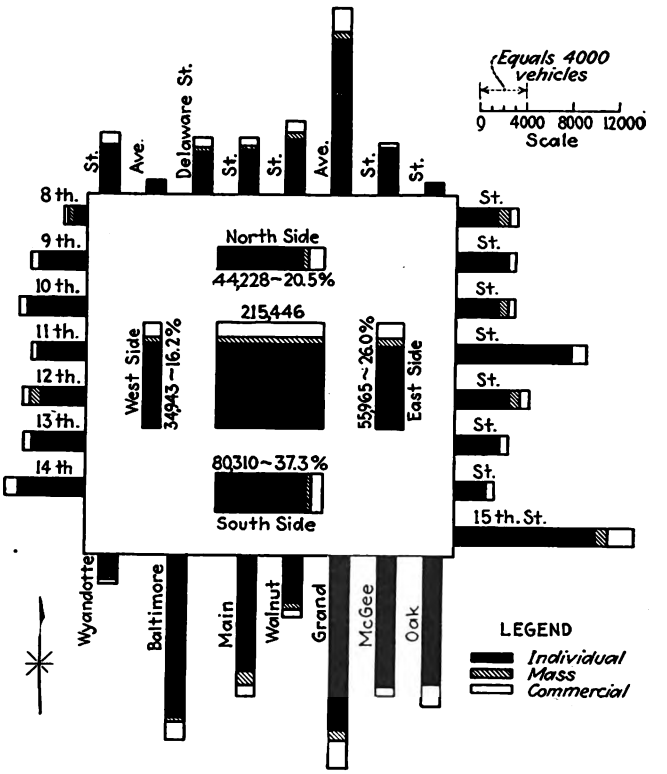
Lowered Accessibility Fosters Decentralization

While it is impossible to effect a complete decentralization of business in any large community without serious violation of economic requirements, yet a tendency toward such decentralization is precisely what is being fostered in every large American city by lowered accessibility resulting from street inconvenience and congestion. The evils of decentralization are not to be found in the logical and normal development of neighborhood business centers. Such centers serve a useful and proper purpose in the economic mechanism of the city, performing services primarily for those who live in the immediate vicinity. General facility of transportation between residential areas and the central business district is quite as important to the development of outlying business site values as it is for the central area.

To determine the trend of community development, a plot was made of all retail drug and grocery stores in the city. These were taken as typical in any neighborhood development. It was noted that the locations definitely followed the principal lines of traffic and transportation activity. The principal vehicular routes as well as the principal railway routes are great stimulators of business activity.

Effects of Mode of Transportation On Purchases

With the co-operation of the Kansas City Merchants' Association and its members, the investigation was extended to determine the relation between the number of purchases and related data with the mode of transportation used by the customer. During a single business day each customer in seventeen of the important retail establishments of the central district was interviewed by sales persons as to the mode of transportation used. The amount of each sale was recorded in relation to the transportation method. It was found that mass transportation, including street cars and buses, contributes almost 60 per cent of the number of purchases made. Total automobile traffic accounts for approximately 33 per cent. Walkers were relatively unimportant in the number of purchases made.



Private automobiles represent 78 per cent of the vehicle traffic in the central district and mass transportation vehicles only 5 per cent

When relative purchasing power is considered, it was found that street car and bus patrons contribute somewhat less than 40 per cent of the total sales volume. Automobile patrons contribute more than 50 per cent of the total value of purchases. As it might be expected, the average amount purchased varies greatly, the individual purchase of the customer arriving in a chauffeur-driven automobile being approximately three times that of the street car or bus rider. This is to be expected, since the street cars and buses carry workers in the central district who make purchases incidental to

Digitized by Google

their daily work, while those who are driven into the district by chauffeurs come for specific purposes, particularly for making large purchases.

Another survey was made to determine the time at which sales are made. The peak in number was found to be between 12 o'clock noon and 1 p.m. The late afternoon hour, from 5 to 5:30 p.m., showed a marked decline. This was believed to be because the time remaining after the offices closed was too short to attract persons making substantial purchases. The value of sales, however, did not follow this same trend, the maximum being reached between 2 and 3 p.m. This latter corresponded with the maximum number of persons checked into the store by actual count.

As a result of this survey it was recommended that the retail store hours be changed so that they will open at 9:30 a.m. and close at 6 p.m., instead of opening at 9 a.m. and closing at 5:30 p.m. This would not only remove the store employees from the mass transportation vehicles at the time when office workers are traveling, but would give office workers, leaving their places of business at 5 p.m., a full hour for shopping.

Study of automobile parking was given a great deal of consideration. Apart from loading and unloading and stopping of vehicles at the curb for a short time while persons are engaged in shopping or other business activities, the principal use of the parking space is by those who leave their automobiles all day or for a long period. On this point the report says:

> Need for facility of movement and maximum use of existing curb space leaves no legitimate place in the control scheme of any congested business district for long-time parking. It is a very low-grade use of valuable public property, every foot of which is required for maximum business activity. It is only equitable to both business concerns and to the general public to require that this type of parking be ruled from the streets and provided for in private facilities.

Actual measurements showed that, while all of the curb space in the central district would be sufficient for parking 8,900 more automobiles, deductions for fire hydrants, driveways, alleys, bus zones, safety zones and no parking areas leave only 4,315 spaces available for general parking during the business day. Within the same district there are off-street terminal facilities for 15,165 cars. Kansas City is thus in a more favorable position with respect to intown automobile terminals than any other city of comparable size for which figures are available.

Observations of all parked cars by half-hour periods during a normal business day resulted in checking 34,076 vehicles. The average parking time was one hour and two minutes making a total of 35,358 vehicle-hours. Of the vehicles, 26,621, or 78.12 per cent, parked one hour or less. Parking was found to build up rapidly in the morning. Until shortly after 8:20 a.m. the parking load exceeds the legal capacity. From 9 a.m. to 5 p.m., however, the load of parking never exceeds the maximum legal limit and indeed falls substantially below. The surplus of curb space revealed during the hours of the business day is in the lighter business streets, while in typical blocks in the more dense traffic area there is an almost constant overload of parking during all hours. An analysis of the parked vehicles showed that almost 10,000 were parked where parking is prohibited. Since prohibited parking is the easiest of all regulations to enforce, this indicates a definite laxity in enforcement policy. Violation of time limit accounts for the second largest class of parking violators, more than 4,000 vehicles being so checked.

Major Transportation Methods of Customers Compared

City	Per Cent of Total Number of Customers Recorded		
	Public Carriers	Walkers	Automobiles
Kansas City	60.41	5.88	33.71
Washington	57.23	11.22	31.55
Chicago	72.50	19.50*	8.00
San Francisco	60.20	21.80*	18.50
Boston	62.00	23.70*	14.30

*Including those walking from suburban trains.

The remainder of the report is devoted to special regulations proposed. An immediate expansion of the central district signal system is recommended to meet the urgent requirements in the areas adjacent to the territory covered by the present installation. Traffic signs and traffic markings are proposed to make it easier to follow the regulations.

With regard to street car operation it is pointed out that numerous operating difficulties and obstructions come from the necessity to run on fixed tracks. When the tracks are occupied by other traffic it is found impossible to proceed, making not only a handicap to street car operation, but an equal handicap in automobile operation. Hence, it is desirable that a minimum obstruction be offered along street car tracks. Accordingly, it is recommended that the practice now followed in the present ordinance of requiring the removal of vehicles from street car tracks upon suitable signal be continued.

Another means of expediting street car traffic is extension of the system of limited stops recently installed on several lines. The elimination of 291 stops in Kansas City has served to increase average speed on the lines affected by 23.1 per cent.

It is estimated that an extension of the limited stop plan to a number of lines indicated will give an average improvement of 28.2 per cent in street car speed and will greatly reduce interference between street cars and other traffic. Some part of the improved railway speed can undoubtedly be attributed to the introduction of the arterial stop plan along many lines.

Cement Specifications Revised

REVISIONS in the standard specifications and tests for portland cement have been adopted by the American Society for Testing Materials. Eleven items in all were included in the revision, of which nine were concerned with tolerances for testing apparatus.

Strength requirements now include the average tensile strength at seven days for the three standard mortar briquets from a minimum of 225 lb. per sq.in. to 275 lb. per sq.in., and the average tensile strength requirement at 28 days from a minimum of 325 lb. per sq.in. to 350 lb. per sq.in. These revisions in strength requirements will bring the minimum values more in line with the general strength level maintained by portland cement plants throughout the country.

Specifications for high early strength portland cement were accepted for publication as tentative. These are the same as the newly revised specifications for portland cement, except that a maximum sulphuric anhydride content of 2.5 per cent instead of 2 per cent is permitted and that tensile strength requirements shall be 275 lb. per sq.in. at one day, and 375 lb. per sq.in. at three days. In addition, the purchaser has the option to require a test at 28 days, in which case the average tensile strength obtained shall be higher than the strength at three days.

Statistical information and publicity data were effectively displayed in the association booth

Successful Canadian Convention

Held at Ottawa

Trolley buses and fare structures were among principal subjects of discussions. Approximately 400 members and guests in attendance

LIVELY interest in ways to improve transportation service was shown by the members of the Canadian Electric Railway Association at their 26th annual convention held at Ottawa, Sept. 17-19, 1930. At three business sessions presided over by the president, C. H. Dahl, vice-president in charge of operations, Winnipeg Electric Company, a well-balanced program was presented covering practically all phases of railway operation. Following the morning sessions, luncheon meetings were held at which prominent speakers spoke on a variety of interesting topics. The business sessions as well as the luncheons were held in the Automobile Building in Lansdowne Park where manufacturer members had arranged an excellent exhibit of equipment and materials.

In his opening address, Mr. Dahl stressed the necessity for placing the railway's problems before the public. He felt that merchandising practices had not kept pace with the accomplishments in improving service, and urged further efforts on the part of the member companies in perfecting their merchandising programs so that the public will understand the necessity for fare revisions and relief from obsolete franchise agreements. The wide variation in the taxes paid by the different companies, according to Mr. Dahl, shows that effective work along this line has been done by some and neglected by others. Mr. Dahl recommended, for careful study, the report of the committee on publicity and merchandising of transportation.

The greater part of the first session was given over to the reports of committees. The committee on rail corrugation reported that the results of experiments made during the year confirmed its previous investigations. It was recommended that all departments of the tramway companies be encouraged to study and improve wherever possible their engineering practice in the design and maintenance of rolling stock and track. Member companies were urged to continue to install trial lots of intermediate manganese or other low-alloy or heat-treated rails, doing everything possible to encourage co-operation on the part of the rail manufacturers in the matter of improved steel making practice and increased heat-treating facilities. Also, the committee asked that all experimental work and trial lots of rail be followed up during installation and service with scrupulous attention to details and the keeping of complete records.

The committee on motor buses and trucks discussed

Digitized by Google

the general use of the bus in city and intercity service, and especially pointed out the value of developing special or chartered business. The committee recommended that efforts be made to establish interline ticket sales and co-ordinated schedules.

The committee on publicity and merchandising of transportation, in its report, emphasized the growing need for merchandising of street railway service. An outline on this wide subject on which individual studies may be based and an extensive bibliography with references to A.E.R.A. reports and technical press articles were submitted.

Deviating from the methods used in the past, the committee on safety and accident prevention during this year centered its efforts in obtaining reports from association members and from companies operating in the United States on definite safety practices which had been tried and proved successful. These reports were summarized and presented to the industry in eighteen letters.

Much Interest Shown in Trolley Bus

The second session of the convention was largely devoted to a study of the trolley bus. E. A. West, general manager, Utah Light & Traction Company, Salt Lake City, presented a paper on this subject in which he gave a résumé of his company's experience during the past two years and prophesied a greater use of trolley buses in the future. He presented information on the problems in equipment and maintenance which were experienced with the original vehicles, showing where the greatest percentages of maintenance costs had been spent. His comparison of costs between trolley bus and street car and gas bus operations was particularly interesting. Dividing them into major cost items, he showed how they were effected or eliminated as follows:

Way and structure costs are eliminated entirely. The overhead system costs should amount to no more than twice the cost of maintaining a railway street car overhead system. Because of the light weight and simple construction of the trolley bus, equipment costs, exclusive of tire costs, will not run over three-fourths those of street railway cars. Conducting transportation will be less expensive than for street railway operation due to the higher average speeds attainable with electric coaches. Power costs should be about one-half those for street railway cars, and less than gasoline costs. The latter are usually higher than street car power costs with only two-thirds the seating capacity of an average street railway car. Trolley buses have seating capacities the same as average-sized street railway cars. Injuries and damage costs will be lower due to greater maneuverability, etc. Gross charges to the depreciation account will be lower on account of the smaller investment.

In general, Mr. West stated that operating experience for two years has shown that the operating costs of trolley buses are about 75 per cent as much as those of a street railway car of the same capacity and 65 per cent that of the equivalent carrying capacity in gasoline buses. The interest aroused by the discussion on this subject showed clearly the serious consideration this vehicle is receiving in Canada.

A paper on street railway fares was presented at the Friday morning session by Prof. Albert S. Richey, electric railway engineer. The speaker discussed the fare situation as it exists in the United States, giving a number of examples of different fare structures and methods of collection. He described the flat-rate fare, the wholesale plan—carrying the regular rider at a less price than the occasional—and the zone system. Discussing what he considers a possibly ideal fare structure, Professor Richey defined it as a charge to each rider closely proportionate to the cost of his ride. He stated, "It costs more to carry the occasional rider than the regular rider. Certainly it costs more to carry a passenger 5 miles than to carry him five blocks. It costs more to carry him any distance in the rush hours than the same distance in the normal hours. These costs are capable of fairly exact determination, and an ideal fare structure might be worked out including a ready-to-serve charge of say 2, 3, or 5 cents with a service or mileage charge of, say, 1 or 2 cents for each additional unit of distance ridden. The ready-to-serve charge might vary with the time of day and with the regularity with which the rider uses the service, while the mileage charge also might vary as indicated by cost analyses, or remain with a fixed relation to distance traveled in fare collection requirements so dictated." To make such a fare structure workable, Professor Richey pointed out that it is necessary to "determine the fare properly due from each passenger, to enable that fare to be collected without delay to the service and properly to audit the collection."

The open discussion on the subject of fares brought out many interesting opinions on a number of experimental fares. J. B. Hayes, manager Nova Scotia Light & Power Company, and Mr. Dahl discussed the weekly pass as used in Halifax and elsewhere. Ralph Emerson, vice-president Cleveland Railway, told of the results of the 2-cent zone experiment in Cleveland and H. E. Weyman, vice-president and general manager Levis Tramways, gave the results of a number of fare changes tried on his system. Walter Jackson, consultant on street car and bus fares, Mount Vernon, New York, also discussed weekly passes and permits.

Under the general headings of traffic, fire protection, operation, and maintenance, a number of scheduled "Timely Topics" were discussed during the sessions. At the first meeting, the subject of the effect of traffic lights on street car operation was introduced by D. E. Blair, general superintendent Montreal Tramways, and discussed by W. S. Irvin, traffic study engineer Toronto Transportation Commission. The need for engineering study, the best available equipment and the careful supervision of the operation of the signal system by a traffic engineer, were stressed by Mr. Blair. Mr. Irvin described the experiences with different signal systems in Toronto. He warned against too many lights in a system, stating that a standard should be set up to justify a signal at any particular intersection. As a result of this discussion on traffic, L. Tait, manager and secretary-treasurer London Street Railway, London, Ontario, moved that a committee be formed to gather data on signal systems and equipment. The motion was passed and a committee appointed at a meeting of the new executive committee on the following day.

Methods used to reduce fire hazards and decrease insurance premiums was the topic discussed at the second session by J. P. L. Ryan, engineer and rating expert Johnston & Higgins, Ltd., and W. E. P. Duncan, engineer of structures, Toronto Transportation Commission. At this meeting, A. M. Lindsay, superintendent of rolling stock Montreal Tramways, described the operating features of cars recently purchased by Canadian electric railways.

Welding, as applied to track maintenance and bus

Digitized by Google

inspection methods, were the topic discussed at the third session. W. A. McRae, engineer of way Toronto Transportation Commission, and J. T. McCarty, manager Metal & Thermit Corporation, led the discussion on welding. H. R. Holder, superintendent of auto bus department Montreal Tramways, discussed bus maintenance.

Luncheon Meetings Popular

At the first luncheon meeting Charles Gordon, managing director American Electric Railway Association, was the principal speaker. He directed the thoughts of the members to the important economic part that the railways play in a community, and showed how the successful operation of mass transportation affected property values, growth of business and the general well-being of the district served. Mr. Gordon dwelt on the traffic congestion problem and pointed out that its solution should be one of the fundamental considerations of a public transportation facility. "Movement of people, not vehicles," said Mr. Gordon, "must be uppermost in the minds of those attempting to solve the traffic problem in any city."

Hon. T. Ahearn, P.C., president Ottawa Electric Railway, was the speaker at the second luncheon. He gave an interesting history of the development of the Ottawa Electric Railway from the days of the horse car up to the present time. He told how, in the face of almost incredible difficulties, the first electric service was carried on during the first winter under very severe weather conditions.

At the conclusion of Mr. Ahearn's address, John A. Miller, Jr., editor Electric Railway Journal, presented to Mr. Ahearn a certificate of merit won by the department of rolling stock and shops of the Ottawa Electric Railway. Announcement of this award is made elsewhere in this issue.

The street car and individual automobile service was the subject of a talk by T. Fitzgerald, vice-president and general manager Pittsburgh Railways, at the third luncheon. He showed how the popular acceptance of the automobile, the development and construction of highways and the growth of other forms of individual transportation facilities had affected street car operations in the United States. He urged the railways to realize that these modes of transportation were here to stay and that the future of the electric railways depended on rendering service which approached the automobile in speed, comfort and convenience.

At the last business session of the convention, the following men were elected to serve as officers for the coming year:

Honorary President—Hon. T. Ahearn, P.C., president Ottawa Electric Railway.

Honorary Vice-President—Acton Burrows, proprietor *Canadian Railway and Marine World.*

Honorary Advisory Council—Edward Anderson, K.C., president and general manager Winnipeg Electric Company;

Lieut.-Col. J. E. Hutcheson, vice-president and managing director Montreal Tramways;

Charles A. Magrath, chairman Hydro-Electric Power Company of Ontario;

W. G. Murrin, M.I.E.E., president British Columbia Electric Railway;

J. F. Saint-Cyr, chairman Montreal Tramways Commission;

Julian C. Smith, LL.D., M.E., president Montreal Tramways.

President—L. Tait, manager and secretary-treasurer London Street Railway.

Vice-President—George E. Waller, vice-president and manager of transportation Dominion Power & Transmission Company.

Treasurer—H. C. Patten, comptroller Toronto Transportation Commission.

Auditor—J. E. Richards, manager and treasurer London & Port Stanley Railway.

Executive Committee—The president, vice-president, treasurer, immediate past-president (C. H. Dahl, vice-president in charge of operation Winnipeg Electric Company), and:

D. E. Blair, general superintendent Montreal Tramways;

Maj. F. D. Burpee, vice-president and manager Ottawa Electric Railway;

W. J. Cunningham, superintendent Edmonton Radial Railway;

A. V. Gale, general manager, Hull Electric Company;

W. S. Hart, vice-president Three Rivers Traction Company, and treasurer Quebec Railway, Light & Power Company;

D. W. Harvey, general manager Toronto Transportation Commission;

C. J. Moors, manager Fort Williams Electric Railway;

W. R. Robertson, general superintendent Ontario Hydro-Electric Railways;

K. B. Thornton, general manager, Montreal Tramways;

H. E. Weyman, vice-president and general manager Levis Tramways.

LEONARD TAIT

New President Canadian Electric Railway Association

LEONARD TAIT, the new president of the Canadian Electric Railway Association began railway work in 1899 as a clerk with the Michigan Central Railroad, at London. He also served with the Grand Trunk Railroad and the Canadian Pacific Railroad, and returned to the Michigan Central Railroad in February, 1905, as chief clerk to the freight and passenger agent, London. He was appointed freight agent of the New York Central Railroad at Toronto, and in November, 1912, became secretary-treasurer of the London & Lake Erie Railway. In 1917 he became secretary and treasurer of the London Street Railway, which position he held until October, 1924, when he became manager and secretary-treasurer.

The afternoons of each day were given over to the inspection of the exhibits. Leading Canadian manufacturers as well as a number of American manufacturers were represented.

Following the luncheon on Friday a meeting of the new executive committee was held. It was decided to continue committee activity during the coming year along substantially the same lines as during the year just ended, with the exception that a new committee was created to study the subject of traffic control. The personnel of the committees was also decided. Considerable discussion occurred concerning the best date and location for the association's 1931 convention. It was decided, however, that the final decision on this subject should be deferred for the time being.

Many entertainment features were enjoyed by the delegates. A cabaret dinner followed by dancing was given at the Chateau Laurier on Wednesday evening, and on Thursday evening the grand ball was held. On each day, entertainment was planned for the ladies of the party. On Wednesday a bridge tournament was held in the drawing room of the hotel, on Thursday a sightseeing motor coach tour to points of interest in the Ottawa district was made and on Friday a golf tournament was arranged.

Canadian Properties Continue Excellent Record

STATISTICS of the electric railway industry in Canada, which have been collected and published by the Canadian Electric Railway Association, have been issued for the fourth successive year by the secretary, Eustace Smith, Jr. In the main they follow the form used last year, and abstracted in this paper for November, 1929, page 1049.

Growth of the industry continued through the year 1929, the passenger revenue having increased more than $2,000,000 from 1928, and reaching a high point for the Dominion. The growth from 1900 is given in Table I. Passenger revenue per mile of single track is now 2.58 times as great as it was in 1900, but the trend of operating expenses per track-mile is 3.07 times as great. However, the operating expenses per mile of single track decreased last year for the first time since the post-war peak in 1920. The use of one-man cars has been an important factor in that movement.

For the past several years there has been an improvement in the financial situation of the Canadian companies. While deductions from income have grown steadily the reduction in operating expenses has made it possible to meet all obligations. In 1921 only 19.5 per cent of the total revenue was available to pay interest and dividends; in 1928 the amount available was 33.33 per cent, as against 32.96 per cent in 1927. Wages, however, continue upward, being 98.6 per cent higher last year than in 1913 and nearly 3 per cent higher than in 1928. The rise is nearly twice as great as the increases shown in fares and living costs.

During 1929 the automobile registrations in Canada continued to increase, reaching a total of 1,193,889. This was 133,000 more than in the preceding year, and represents the greatest growth in any single year recorded. The growth in registrations has been fairly steady from 50,000 vehicles in 1913.

The number of revenue passengers continued approximately the same until the end of the war, with a sharp increase to a maximum of 804,711,333 in 1920. Subsequently there was a decline and the top figure was not exceeded until 1928. Last year, however, there was another marked increase to 3.25 per cent above the 1920 peak, making the largest number of street railway passengers ever carried in Canada. In the face of the large increase in automobile registrations in the past four years this showing is considered particularly encouraging.

There has been a remarkable development of the motor bus in Canadian transportation, according to the report. In the figures it is possible to distinguish between feeder buses and special coaches used for interurban work, special fare routes, charter and sightseeing service. From 13 buses operated by electric railways in Canada in 1921 the total has grown to 540 in 1929. The growth is particularly marked in the last four years. In 1929 the number of coaches was 264, an increase of 18 per cent, and the number of feeder buses was 276, an increase of 4 per cent, over the preceding year.

There has been a distinct trend toward the absorption of independent bus lines by the electric railways. Many of these lines running on suburban and interurban routes have been carrying passengers to the centers of the cities and depriving the street railways of their passengers and revenue, according to the report. During the past two years electric railways have purchased the larger and more important independent bus lines directly or indirectly in competition.

As to the comparative efficiencies of passenger vehicles in mass transportation, traffic counts in a typical Canadian city are cited. During the evening rush hour on normal week days in February, 1930, street cars comprised 8.1 per cent of all passenger vehicle movements and 5.08 per cent of all traffic movements, carrying 78.8 per cent of all passenger traffic and occupying 24.1 per cent of the street space taken up by all passenger vehicles. Buses comprised 0.7 per cent of all passenger vehicle movements, carried 1.3 per cent of all passengers and occupied 1.4 per cent of the street space taken up by all passenger vehicles. Automobiles comprised 91.2 per cent of all passenger vehicle movements, carried 19.9 per cent of all passenger traffic and occupied 74.5 per cent of all street space taken up by all passenger vehicles.

During the hour in question there were 466 outbound motor street cars and 200 trailers carrying 57,265 passengers, or an average of 86 passengers per car. In the same period there were 7,486 automobiles carrying 14,422 passengers, or an average of 1.93 passengers per car. It would, therefore, require 45 automobiles to carry the same number as the average street car.

Financial and operating statistics of Canadian electric railways for the years 1922-1929 compiled by the Dominion Bureau of Statistics are given in Table II.

Table I—Canadian Electric Railway Passenger Revenues, 1900-1929

Compiled by Canadian Electric Railway Association

Year	Passenger Revenue: Total	Passenger Revenue: Per Single-track Mile	Passenger Revenue: Trend	Operating Expense: Per Single-track Mile	Operating Expense: Trend
1900	$5,529,687	$8,192	100	$5,237	100
1905	8,932,914	11,265	138	7,463	141
1910	16,125,994	11,660	143	7,319	140
1915	25,579,689	12,211	150	8,622	165
1920	43,279,009	17,832	218	15,757	300
1925	45,185,402	17,616	216	13,811	264

Short Signal Cycles

Speed Traffic and Reduce Accidents

A study of pedestrian psychology in relation to traffic and transportation shows that long cycles will not be observed by all walkers

REDUCTION by one-quarter or one-half of the hazard of pedestrians crossing traffic and transit streets, through the application of design and the intangible factor of human psychology alone, seems worthy of serious consideration by those using and controlling our streets. Mechanical methods and automatic devices often neglect this factor. In the pages of the JOURNAL have been discussed, from time to time, the theory, practice and results of signaling, both good and bad, and their ultimate effect on transportation speed, traffic congestion and pedestrian safety.

Some transportation men, struggling to maintain reasonable speed through the heavy traffic districts, are disposed to let the pedestrian take care of himself, forgetting that all those who use public transportation are pedestrians at some stage of their journey, especially in the signaled zones. On the other hand, most traffic officials succumb to the pressure of unadvised local public opinion, demanding "better pedestrian protection," and as a result, usually impose unnecessary restrictions under which both transportation and traffic fare badly, indeed. Few of these officials seek data to determine the proper balance, and rarely do they take the trouble to ascertain either the dynamics or psychology of the problem.

The whole question was brought to focus by the writer in a recent signal survey under the most severe metropolitan conditions where transit speeds had been brought down to 4 m.p.h. by improper signal control. Here the traffic authority arbitrarily demanded that traffic controls and signal timing should provide sufficient time for the slowest walker to meander across the street from curb to curb, 100 ft. In this survey the normal habits of some 60,000 pedestrians in crossing the streets were timed by stop watch. Fig. 1 shows the results. Taking the group as a whole, the weighted average walking time to cross the 100-ft. street was 20.5 seconds or 4.86 ft. per second (3.3 m.p.h.). Of this total, the "actives" represented 84 per cent; males averaged 5.3 ft. per second (3.6 m.p.h.); the women 4.6 ft. per second (3.1 m.p.h.). The "inactives," men, women and children, 14 per cent of the total, varied between 20 and 24 seconds crossing time, averaging 4.4 ft. per second, (3 m.p.h.). The last class, "slows," very old men and women, cripples and nurse maids strolling across with baby carriages, representing about 2 per cent of the total, took from 25 to 31 seconds, averaging 3.6 ft. per second (2.4 m.p.h.).

The signal system allowed two minutes in the direction of heaviest traffic and one minute for cross traffic. In the center of one of the thoroughfares was a grassed parking strip with fencing, offering perfect pedestrian protection. All "slows" and "inactives" could use it for half-crossings. Despite this, the traffic authority rejected any signal design that would not provide at least 35 seconds cross time at any point, corresponding to a walking speed of only 2.9 ft. per second (1.95 m.p.h.). This interval is three-quarters greater than for the "average" and nearly one-half greater than the time required by "inactives."

The question is, then, what is the fair basis for minimum pedestrian time? And should the signal system be designed for protecting the 98 per cent of active people or the 2 per cent "slows" who always have the protection of the central refuge zones, where they can fall back of the procession with full safety?

This difference between the possibility of half-crossings vs. full-crossings is really the difference between an efficient and an extremely inefficient signal design. The former can produce reasonable non-stop "progressive" traffic movement with very little wastage of crossing time; the latter must involve great time wastage. In practice this always appears as so-called congestion, which is really not congestion at all but unnecessary stoppage.

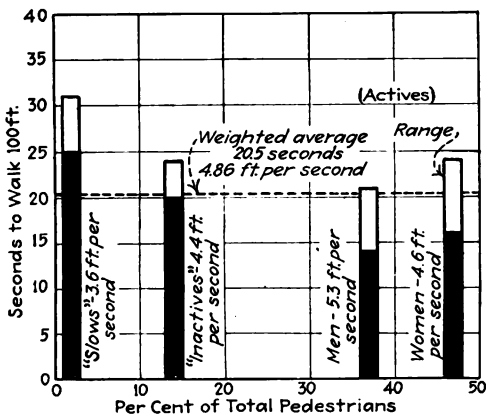

Fig. 1—How long it takes to cross a 100-ft. street was determined from a count of 60,000 pedestrians

The effect of human psychology is very definitely illustrated in this survey. Traffic authorities have imposed on traffic and transportation absolutely rigid restrictions, but enforce none whatever upon pedestrians. In the great city of New York all main traffic is stopped one minute out of every three minutes, or 33 per cent of the time; cross streets just the reverse—all traffic stops two minutes out of every three minutes, or 66 per cent of the time.* The same situation obtains on Michigan

*Within the last few weeks the signal cycle in New York has been shortened to two minutes, consisting of 85 seconds north-and-south and 25 seconds east-and-west, with 5-second stop periods between.

Digitized by Google

Boulevard, Chicago. All traffic on the north side of the river stops every 100 seconds for 35 per cent of the time; on the south side of the river, traffic stops every 150 seconds for 40 per cent of the time.

And what about the pedestrian himself—his habits, his appreciation of these rigid police requirements imposed upon all traffic, and, of course, all car-bus riders, who form the major volume in daily population movement? Do pedestrians obey these restrictions equally or are they even required to do so by city ordinance and street police enforcement? The answer is well indicated in Fig. 2. Here are analyzed the habits of these 60,000 pedestrians crossing two important streets, one a main high-speed artery and the other a heavy crosstown thoroughfare. The survey recorded in detail two groups. The first obey the signals, crossing only on green. The remainder violate the red "Stop" signal, which traffic

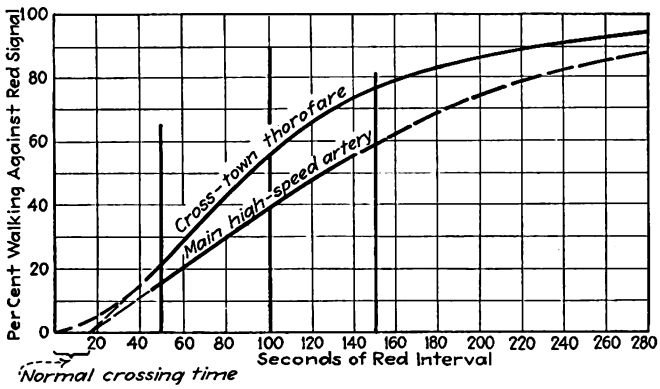

Fig. 2—Violations of the red signals by pedestrians go down as the cycle length is reduced

and transit have to observe for their protection. This expresses the hazard factor. This group is plotted with relation to per cent volume and the length of the red interval.

The disturbing fact appears from this study that the large majority of pedestrians, two-thirds in fact, violated the red signal and deliberately crossed through traffic without waiting for the green, and even without making use of the refuge zones provided for their further protection. The curve "Percentage of Violations" is based upon two main series of timed crossing intervals, one minute and two minutes respectively. Its necessary relation to the origin on the one hand, and on the other the known fact that with still longer signals everyone would finally cross against the red, renders the extrapolation of the curve fairly accurate. While about two-thirds of the pedestrians actually crossed against the long red signal, only a little over one-quarter walked against the short red. As the cycle is shortened, the proportion of violations decreases at even faster rate than the interval itself.

This is the key to the signal situation on all wide thoroughfares. Carrying forward this analysis, in Fig. 3, the "Hazard Curve" per second of red interval is the first derivative of the basic curve of "Percentage Violations." As the cycle is shortened, it is clear that the pedestrian hazard also falls much faster than the proportion of violations. Indications are that with a 20-second red interval, the hazard would be perhaps only half of that for a 30-second red interval, the latter only about a third of that for a 60-second red interval, etc. The writer believes that further investigation should be undertaken, particularly of shorter intervals, at a given crossing where different red and green intervals can be obtained through a wide range. Comparing one street with another is not fundamentally accurate and is liable to give variable and obscure results.

From the preceding it seems to the writer that we must entirely revise our ideas as to protection of pedestrians when they neglect their own interests so far as indicated in this study. It is equally obvious that those traffic authorities who still adhere rigidly and blindly to the old long cycles are defeating their own objective in

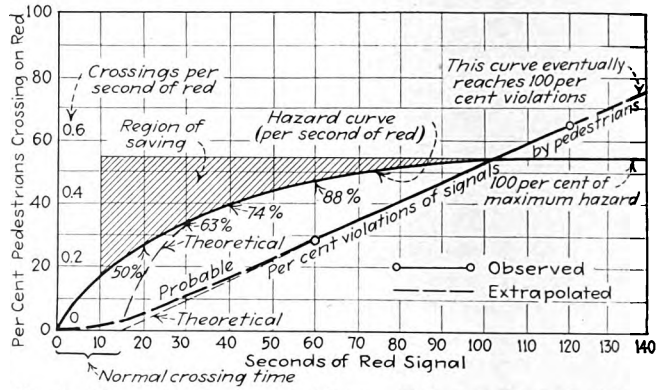

Fig. 3—Short signals save accidents. This was determined by a study of 46,000 observations on a major crosstown thoroughfare

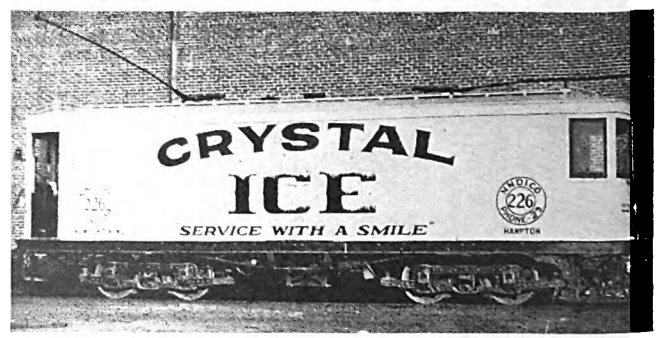
best serving the public, not only increasing pedestrian accidents, but causing a tremendous delay to all.

The flexible progressive signal system can be designed to abate or remove these hardships. With reasonable crossing intervals, it is safe to say that our signal systems can be vastly improved, somewhere near in proportion to the improvement in efficiency which the public demands of modern transportation. As a basic approach to this re-design of signals, the writer would suggest that a "normal" crossing time of roadways of 4.5 ft. per second (about 3 m.p.h.) should be used. Furthermore, that very wide thoroughfares, if they are ever to be signaled with any degree of efficiency, must have center refuge zones permitting half-crossings where reasonably needed.

This question of the pedestrian walking time, and his psychology in refusing to conform to the same rigid regulations required of traffic and transit lies at the bottom of the problem. However, American citizens are independent-minded, but amendable to reason and cause. Where armies of policemen are relatively powerless, a little psychology will succeed at practically no cost.

Ice Cars Advertise Product of Railway Subsidiary



Cars operated by the Virginia Public Service Company in a co-operative freight service with its subsidiary, the Newport News Distilled Ice Company, are used to stimulate the latter's business by attractive advertising

One substation contains three 3,000-kw., 3,000-volt synchronous motor-generator sets, each with high-speed circuit-breaker protection. The other substation is similar but only two sets are installed at present

Motor Generators

Supply Power for Cleveland Terminal Electrification

Two substations, one at each end of the system, furnish direct current at 3,000 volts for operation of trains on this heavy electrified system. Complete automatic protection is afforded for all circuits and machines

By
G. R. McDONALD
Transportation Engineering Department
General Electric Company

POWER for the 3,000-volt direct-current overhead contact system of the Cleveland Union Terminals Company is supplied by two synchronous motor-generator substations located approximately 8 miles apart. One station, near the western, or Linndale, end contains three 3,000-kw. units. The other station, about 7 miles east of the terminal, has an initial equipment of two similar units, with an ultimate capacity of three units. The buildings are practically identical, having inside dimensions on the ground floor level of 84 ft. x 83 ft. 8 in. The buildings are divided into three sections, with the main motor-generator room in the center, the alternating-current incoming lines and switching equipment at one side, and the main switchboard and direct-current switching equipment on the other. Ample headroom in the main machine room provides ventilation and the necessary space for an electric crane.

The incoming, or a.c., side of the building is completely walled off from the central machine room. The main switchboard on the other side of the building and the gallery directly above the main switchboard are open to the machine floor. At the Linndale station, the incoming a.c. lines from the Cleveland Electric Illuminating Company enter through six lines of underground cable, which come up to the main floor level through six incoming line breakers and thence to the two bus tie breakers. This bus, located in the basement, is in three sections, each fed by two of the incoming lines. The two tie breakers are so arranged that sections 1 and 2, or 2 and 3, may be connected. The main-line machine breaker and station service breakers are also located in the basement. The arrangement of the east substation is similar, except that the present installation includes only four incoming cable lines. All of the a.c. breakers, with the exception of the starting and running units for the machine, are designed for 15,000 volts and a normal capacity of

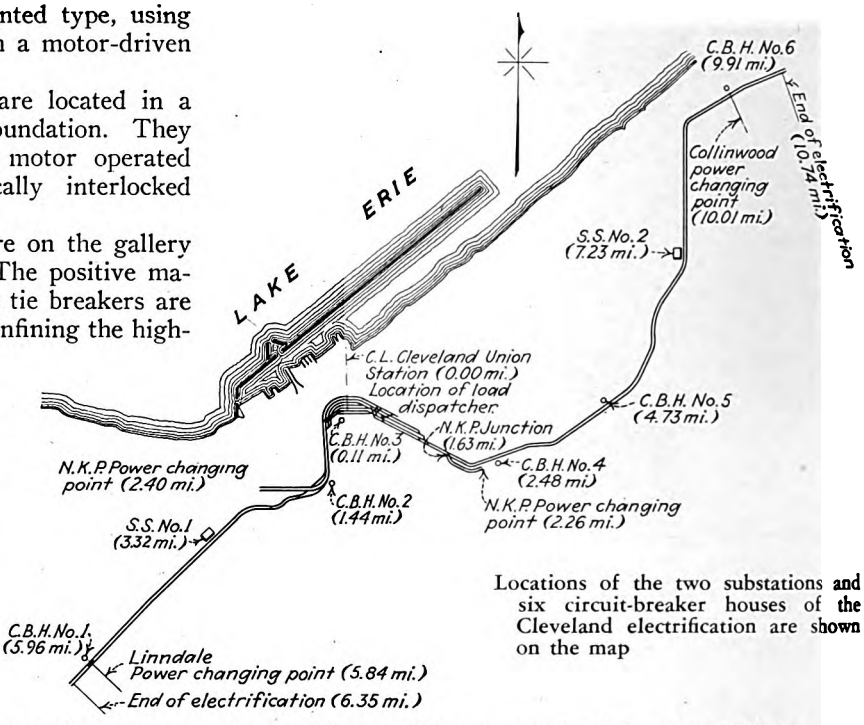
Digitized by Google

1,200 amp. They are of the cell-mounted type, using three separate tanks, and provided with a motor-driven closing mechanism.

The starting and running breakers are located in a cell structure adjacent to the machine foundation. They are also of the three-tank type with motor operated mechanism, electrically and mechanically interlocked against simultaneous operation.

The main and auxiliary d.c. buses are on the gallery directly above the main switchboard. The positive machine breakers, feeder breakers and bus tie breakers are all mounted on the bus structure, thus confining the high-voltage d.c. switching to the gallery.

As a further precaution, all of the relays and other devices used directly on the 3,000-volt circuit except the voltmeters are segregated from the rest of the control and located on a panel in the gallery. The negative machine breakers are mounted adjacent to their respective machines on the main floor. All of the d.c. switching is done by high-speed circuit breakers.



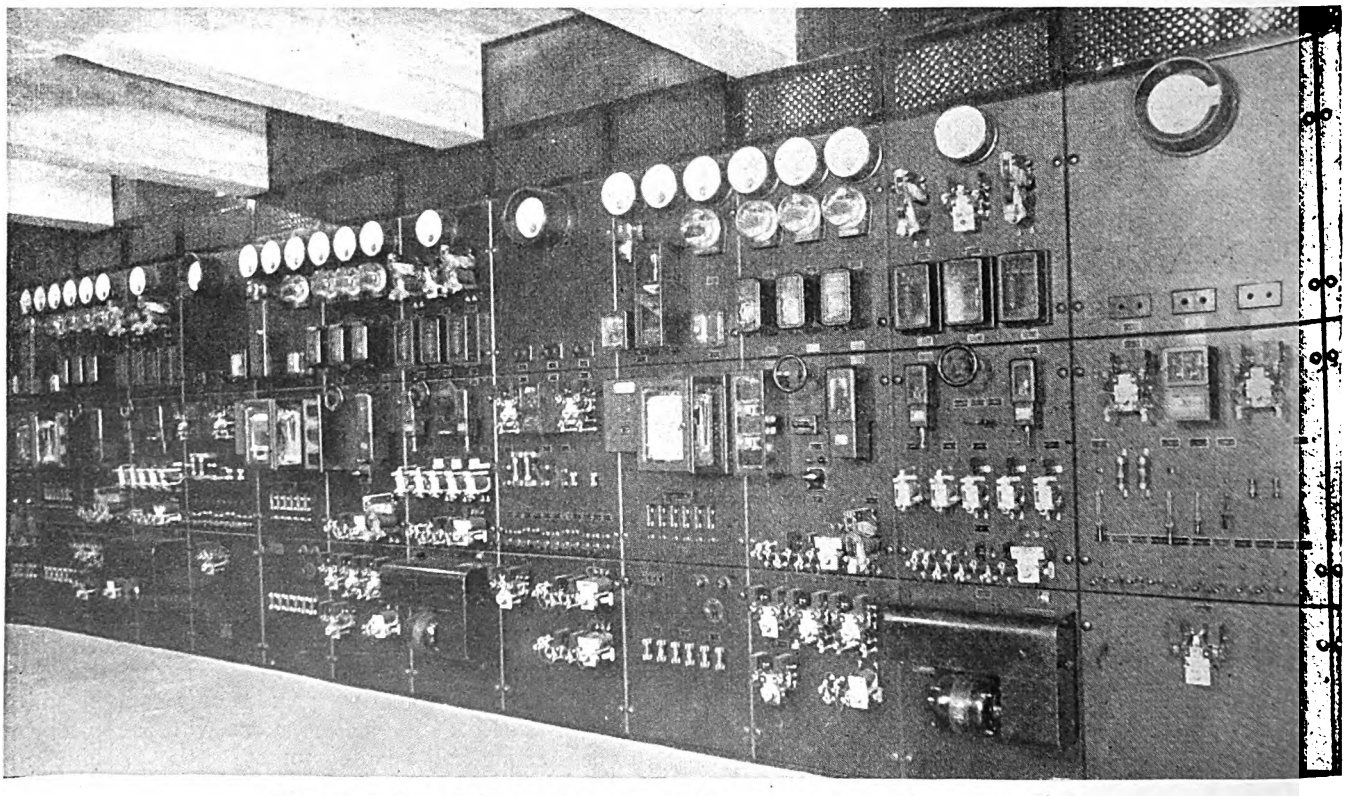
Locations of the two substations and six circuit-breaker houses of the Cleveland electrification are shown on the map

Located in the basement of the station is a Reed continuous-type air filter and a motor-driven fan for each motor-generator set. Ventilating air is taken from outside, cleaned by the air filter and then passed into the foundations of the set. The machines take this cool air from below and discharge it into the main room, whence it finds its way out through roof ventilators.

Main Converting Units Are Motor Generators

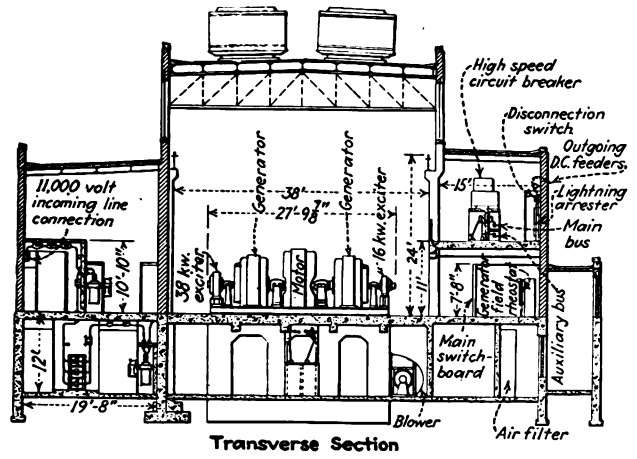
The motor-generator sets for converting the 11,000-volt, 60-cycle supply to 3,000-volt d.c. are of the three-unit type, nominally rated 3,000 kw. They are designed for handling a 300 per cent load for five minutes, or a 150 per cent load for two hours, after a constant temperature has been attained at normal load. The synchronous motor of the set is rated 3,600 kva. at 360 r.p.m., and is direct coupled to two 1,500-kw., 1,500-volt generators permanently connected in series.

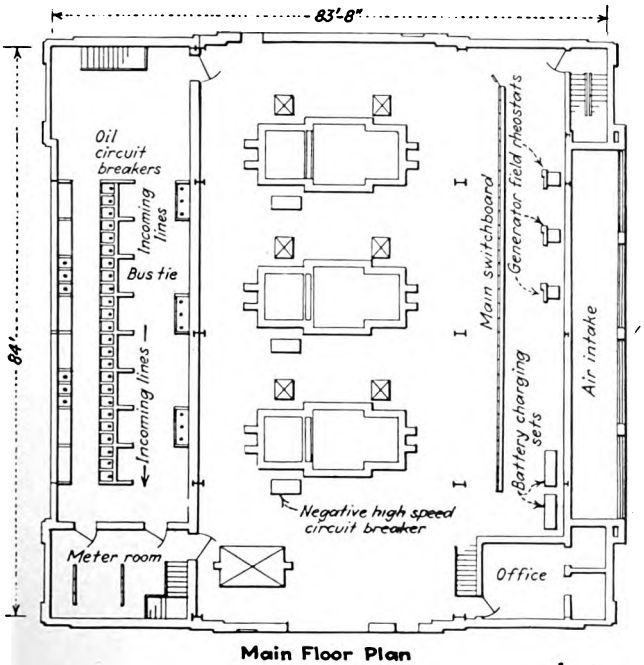
The set is equipped with two exciters. One, rated 16 kw. at 125 volts, supplies power to the fields of the two generators and the second exciter. The other exciter, rated 38 kw., supplies current for the motor field, operating through a range from 40 to 140 volts. This unit also has a series field coil which carries the main load

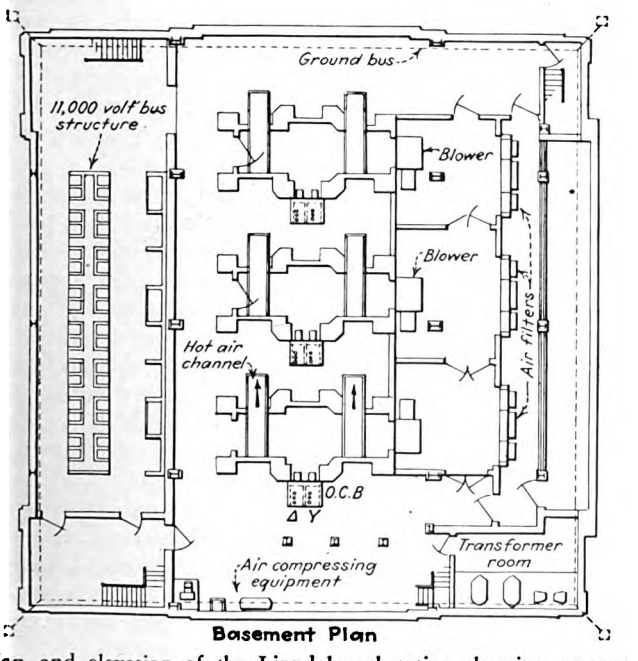


The automatic switching equipment provides complete protection to all circuits

Digitized by Google







Plan and elevation of the Linndale substation showing arrangement of the motor-generator sets and switching equipment

direct current, compounding the exciter voltage and hence the motor field in proportion to the load. This gives a practically constant power factor up to 300 per cent load. At light loads, the power factor has a tendency to lag. In order to compensate for this a relay cuts out a portion of the exciter field rheostat at light loads, increasing the excitation and maintaining a practically uniform power factor throughout the complete range.

The synchronous motor armatures are wound for the incoming power supply at 11,000 volts and no step-down transformers are required. The motor windings are connected in Y for starting and in delta for running, obviating the use of auto-transformers.

Both Local and Remote Supervisory Control Used

The motor-generator sets may be started by either local or remote supervisory control, as determined by the position of a selector switch in the substation. If a.c. power is available and all of the protective devices indicate that the set itself is in condition to be started, closing of a control switch to start up a motor-generator set will actuate a master contactor which, in turn, initiates the sequence. Starting voltage is supplied to the motor, and the set is brought up to speed. The field of the motor is then partially excited with a value of field current which will provide the best condition for making the transfer from starting voltage to full voltage.

As soon as the motor field is properly established, the motor windings are changed from the Y starting connection to the delta running connection. This scheme provides a very smooth transfer from the starting to the running voltage, as during the change from Y to delta there is a 30-deg. shift in the electrical position of the motor windings. The windings are so connected that this phase displacement compensates for the slowing up of the rotor during the time of transfer, and it happens that the amount of drift back of the rotor, during this period, corresponds to almost the 30 deg. made by the change in the winding connections. Next the negative high-speed circuit breaker is closed and the voltage of the generators allowed to build up. One of the two positive breakers is then closed and the generators are ready to have their voltage adjusted to the correct point for connecting to the d.c. bus.

All of the d.c. 3,000-volt switching is done by means of high-speed air circuit breakers. One of these, connected in the negative side of the set between the commutating field and the armature of one of the generators, is set to trip on severe overload or short circuit. On opening, it inserts a limiting resistor in series with the generators and reduces the current to a nominal value. At the same time, interlocks on it open the positive breakers and operate a "field-killing" contactor which inserts a resistor in the generator shunt field circuits. The series and commutating fields of both generators are on the low side of the negative breaker and are consequently connected solidly to the negative bus and the rail. With this arrangement it is not necessary to provide any more insulation for these fields than is ordinarily used for lower-voltage machines. For the positive connection to the bus there are two high-speed breakers, one merely used as a contactor device, while the other is so connected that it will trip on reverse current. This latter breaker provides fast protection if for any reason power is fed from the a.c. bus into the set.

When a set is shut down the field rheostat is run to

Digitized by Google

a point corresponding to slightly less than normal voltage. While starting, field current is not supplied to the main generators, as the field-killing contactor remains open until after the change is made from starting to running voltage on the motor and the negative high-speed breaker has closed.

If the unit is the first to be started in the station it will not be connected in unless the bus voltage is below normal. A voltage directional relay, together with an indication of low bus voltage, causes the positive line breaker to be closed.

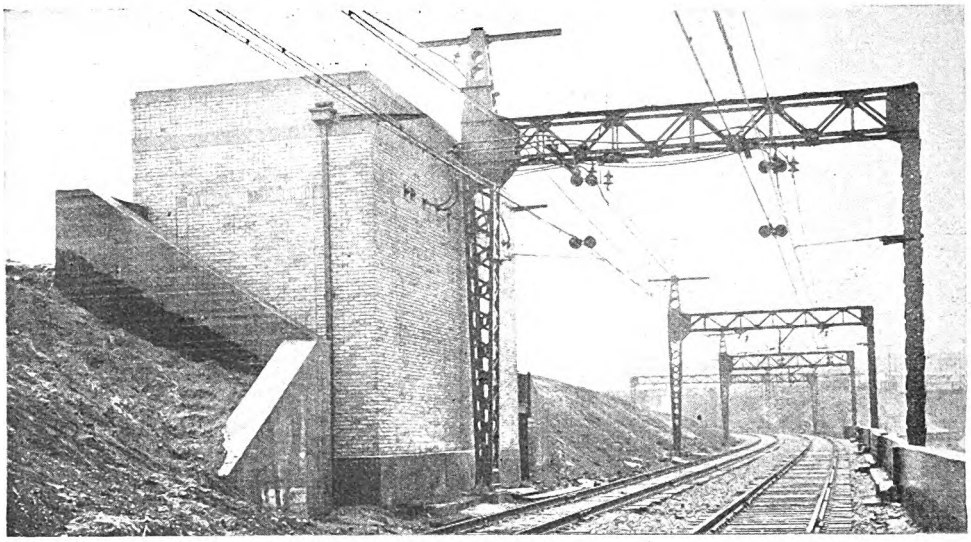
If the bus voltage indication was at normal when this set was started, it would not be connected to the bus but would merely run idle until a reduction in the bus voltage (indicating that a load had caused a drop in the voltage supplied by the adjacent station) would cause the set to be connected to the bus.

Much the same action takes place if other sets are running in a station. However, the voltage-regulating relays then function to maintain the bus voltage at all times. Consequently a reduction in bus voltage cannot be used as an indication of the presence of load, but a current relay, one of which is associated with each machine, gives the necessary indication.

The method of regulating the station voltage and of adjusting the load between the various units is especially interesting. A voltage-regulating relay is connected across the station bus. If a single unit is operating, this relay will function to maintain the bus voltage by controlling the motor-operated field rheostat, and will maintain approximately constant voltage between no load and the maximum rating of the set. At this point the control is taken from the voltage relay by a current relay which will act to maintain constant current output of the set as long as the load demand stays above its maximum current rating. If the set tends to stay at maximum current output for a time exceeding its rating, a thermal relay, which provides an integrated check on the heating, will act to reduce the load on the set.

When two or more units are operating, the control is very similar except that it is modified by load-balancing relays which tend to equalize the load. If the load is equally divided among all the sets, the voltage-control relay will raise or lower all of the field rheostats simultaneously to change the bus voltage. If two sets are operating and the load is not properly balanced, the load-balance relay will tend to restore the balance. One of the units is regarded as leading and the other unit is always belanced with respect to it. By this means the load will be gradually divided properly between the various units, and the rheostats will be controlled in a manner very similar to that followed by an operator.

If two or more sets are operating in multiple and the load is reduced so greatly that one of them tends to reverse, a reverse-current relay, set to act at a very small value, will disconnect the set from the line. This set will continue to run idle until load demand reoccurs, when it will immediately be rebalanced with the bus and connected to take its share of the load.



One of the six circuit-breaker houses and the electrified line of the Cleveland terminal system

Six circuit-breaker houses are used for tying together and sectionalizing the d.c. distribution system. One is located near each end of the electrification, the other four are spaced between the two substations. These circuit-breaker houses are small two-story buildings. The control switchboards, batteries and battery charging equipment are located on the first floor. The d.c. bus structure is identical with that used in the main substations and consists of the main auxiliary bus, together with a bus tie breaker. As in the main substation, all the d.c. breakers are of the high-speed type. The only other apparatus are the necessary storage batteries and charging equipment for supplying power for controlling and operating the breakers of the feeder circuits.

Control of all of the feeder circuits and other equipment in the circuit-breaker houses centers in the dispatcher's office. The apparatus is normally operated from there, although manual control is also provided at each location. The control circuits are so arranged that the breakers are entirely trip free. If a breaker trips on after being closed, the control must first be returned to the opening position before it will reclose.

Complete control of the electrical system is centered in the dispatcher's office, which is located adjacent to the train dispatcher's office in the terminal building. From there four wires run to each station and circuit-breaker house over which the load dispatcher has control. By means of an alarm bell and indicating lights, the dispatcher is immediately informed as to any change in the equipment under his control. Telemetering equipment gives a continuous indication of the loads on the various motor-generator sets. The supervisory system used is known as the synchronous selector system.

The machines and practically all the auxiliary equipment were furnished by the General Electric Company.

Prior to the formal opening of the Cleveland Union Terminal on June 28, both of the substations were in operation for several months while the engine crews were instructed in the handling of the new locomotives. Since that time they have been in practically continuous service.

Determining

Utility Depreciation

on a Logical Basis

By JOHN W. BURKE
Consulting Engineer
New York

Depreciation plays a smaller part in the retirement of property than is usually understood, while obsolescence has a major influence. The need for large reserves is open to question

DEPRECIATION, as the term is popularly used, has several meanings. On all constructed property there may be three kinds of depreciation, physical, service and financial. Before placing a money value on the depreciation of the physical property the nature and effect of physical depreciation must first be considered. For further simplification the element of obsolescence, which sometimes is treated as a part of depreciation, is taken up separately. The examples chosen to illustrate this discussion are chiefly elements of urban electric railway properties, which undergo rather more than the average depreciation on public utilities.

Generally, neither an entire property nor an element of it suffers any loss in capability of service until the process of depreciation is far advanced. Indeed, all stationary structures, such as track and buildings, and even the power house and substation machinery, might be depreciated to retirement and replaced with new structures and equipment without in the least affecting the service, or the comfort and safety of the patrons.

To a slight degree only has depreciation an effect on efficiency, sometimes increasing, sometimes decreasing it. A new car or a new machine requires less power to run it after its roughness, tightness and stiffness are worn off by a period of use. Per contra, it will suffer a slight inefficiency near the end of its life on account of wear and increased maintenance expenses.

In the ordinary class of property, depreciation and its powerful opponent, maintenance, are inextricably interwoven. This is the class of property whose life can be extended by maintenance through minor renewals or repairs. However, some minor elements of property cannot be saved by maintenance. A wooden tie, for instance, if of unusually good quality, or if treated with a preservative, or if laid in concrete or in soil constantly wet, or if subjected to very light traffic, will have a longer life than an ordinary tie. But in any event, it must fail through true depreciation, without any aid from repairs. This is true also of many other items. Many parts are retired not through depreciation, but through obsolescence.

When should maintenance cease and depreciation be allowed full sway? Or, when should a depreciable property be retired? The time for such retirement is when the current cost of annual maintenance exceeds the average cost of annual maintenance by the amount of the estimated annual depreciation. But the annual depreciation depends on the life, and the life cannot be known, even approximately, until near expiration. Moreover, the life can be influenced by the extent of the maintenance. Thus the problem contains two variables, life and maintenance, mutually interdependent but bearing an unknown relation one to the other. It can be solved only by judgment and experience.

Of totally different character with regard to depreciation are machinery and vehicles of the internal-combustion type, such as gasoline-driven motor cars, trucks, cranes, hoists and shovels. They are in a class by themselves. The violent vibration of engine, chassis and body produce defects that cannot be remedied by repairs. True depreciation rapidly ensues, and, in the case of automobiles, there is the factor of style obsolescence.

The difficulty, or, in most cases, the impossibility, of drawing a sharp line of demarcation between maintenance and depreciation is well recognized by practical operators. It is reflected also in the accounting orders of some of the public service commissions which require or permit public utilities to show maintenance and depreciation together in one account.

If the net effect, or the algebraic sum of the forces and influences inducing depreciation of the property less the maintenance tending to offset depreciation, be substantially constant, then the rate of depreciation is substantially uniform, and the total or accrued depreciation of the property at a given time would be in the ratio which the age of the property at that time bears to the total time the property will last in given service. This is the "age-life" hypothesis of depreciation. The age-life theorists, however, assume certain arbitrary life periods for the different elements of the property based, not on actual experience, experiment or research, but on the opinions of a few technical writers whose training and experience, in most cases, are entirely inadequate for an intelligent consideration of the subject.

While there generally can be no precise or accurate measure of depreciation on a merely age-life basis, a practical and fairly approximate measure may be had through careful examination of the property by competent, experienced investigators who examine the visible portions of the property. Due consideration is given to the original quality of the element when ascertainable,

Digitized by Google

and to its age, history, past service, and other known conditions. From these data there is a practical determination of the advance of the element toward complete wear-out or retirement through depreciation.

Accrued Depreciation Moderate

Physical depreciation, if unchecked by maintenance or repairs, diminishes, of course, the monetary value. Some elements, like land, are generally not depreciated. Others, like grading, are appreciated. In some instances the entire element is subject to depreciation; in others only a portion of it. For example, steel track rails are retired when roughened or weakened by a wear of less than $\frac{1}{2}$-in. on the head. The salvage value is a substantial portion of the cost new. Altogether, in an average property the portion subject to depreciation is substantially less than the total, and the monetary loss due to depreciation is usually but a small part of the total cost.

The monetary loss from physical depreciation is an operating expense. The annual charge to depreciation should be based on a careful examination of the physical property every few years by competent judges, coupled with the routine records and observation of the operating officials. After a term of years, the accrued depreciation should be the sum of these annual depreciations, less the cost of major renewals or replacements. Minor renewals and repairs are covered by charges to maintenance. The province of a depreciation reserve is to afford a fund for large individual retirements that cannot conveniently be met by maintenance charges in any one year.

In logic and equity, depreciation has no effect on the rate base. The rate base represents the property of the owners. Depreciation is an obligation of the users. Except in rare instances, the owners place in public use elements of property which are entirely new, and they are worn down in the service of the public. It is universally admitted that the public itself must repay this service in some form. Yet some, who concede that fact, still illogically maintain that the accrual of this depreciation through a series of years is not an operating expense but should be charged against capital account in determining the rate base.

In those classes of public utilities whose rates are closely scanned by the public, it is sufficiently difficult to secure adequate rates and of questionable wisdom to attempt to collect, in addition, a theoretical amount for an unnecessary and unjustified excess depreciation. This opinion and some others of those expressed in this article are well illustrated in the testimony of several of the ablest executives and operators in hearings before the Interstate Commerce Commission on its study of depreciation accounting under Docket No. 15100, which has been before the commission for the past seven years.

From the testimony in this case it appears that it is not only difficult and impracticable to separate, even approximately, the elements of the physical property restored by current repairs from those retired at long intervals; but the repairs and the retirements alike are properly chargeable to operating expenses. The actual total cost will be the same, however it be distributed in the accounting. Any elaborate accounting on some age-life hypothesis of depreciation will only add a useless extraneous cost.

Service and Financial Depreciations

Service depreciation is an inefficiency or inadequacy below a first-class standard of service, and is, or may be, due to excessive physical depreciation; deficient or deferred maintenance; inferior design, construction or equipment; inconvenient or unskillful schedules; lack of care and courtesy; lack of harmony between men and management, and other similar lapses in administration. The portion that physical depreciation contributes to service depreciation is generally very small, or entirely negligible.

In the meaning that financial depreciation is a diminution of capital due to physical depreciation of the property, such diminution can never occur under normal conditions of operation and management when the property is properly maintained. In case of sale of private property, the retirement reserve fund should be paid over to the purchaser, or the same result effected by deducting its amount from the value of the property new.

Excessive Reserves Objectionable

Treatment of depreciation from the financial viewpoint was clearly reviewed in Interstate Commerce Commission Docket 15100 by the late Robert A. Carter, then a vice-president of the Consolidated Gas Company of New York in charge of finances and accounts. Before the commission he testified in part:

> Provision for repairs should be treated in the same manner as provision for labor or coal or oil or taxes or similar items of expense. The actual cost of repairs should be charged to the operating expenses. In respect to retirement, in order to equalize the effect of property retired so that a disproportionate burden may not fall upon the operations of any one year, the amount provided should be treated as a charge to operating expenses, and a corresponding amount credited to a retirement suspense account . . . against which items of plant and equipment, actually retired, should be charged. . . .

George C. Mathews, then chief statistician of the Wisconsin Railroad Commission, and who had been a member of the sub-committee of the National Association of Railway and Utilities Commissioners which drafted the National classification, in his testimony said:

> The nature and size of reserves to cover retirement losses will vary both with the size of the property and the degree of diversity in its units. Given properties of similar character, the larger property will have less need of carrying retirement reserves. . . . Equalization is needed only for relatively large units of property. . . . For these classes of property no one can forecast lives. Reserves built up on a life basis will have the appearance of scientific handling, but the substance will be lacking. The life of poles or ties or rails may be estimated with some degree of accuracy, but when we come to the very property against which reserves are needed the life estimates are mere guesses.
>
> The rule proposed in the accounting classifications of the National Association of Railway and Utility Commissioners is sufficient to cover the situation, i.e., that a retirement reserve for large sections of continuous structures is sufficient. . . . Proper and adequate reserves need provide only against extreme fluctuations in retirement losses, and experience and judgment should not be subordinated to life tables which, except by accident, cannot be correct.

Besides the large amount of pertinent information brought out by the hearings in I.C.C. Docket 15100, there are similar data found in numerous cases before the courts, all subscribing to the view that large depreciation reserves are unnecessary.

Age-Life Hypothesis Not Borne Out

There is a sharp contrast between the practical and authoritative opinions given in such testimony and the ideas of the age-life proponents. The popular idea of age-life depreciation contains sufficient plausibility to intrigue the impractical or inexperienced. In relation to public utilities it was accepted by many as a prudent provision calculated to safeguard the interests of both the rate payer and the investor. But careful observers

Digitized by Google

soon discovered that, on the life tables commonly used, it had a tendency to build up excessive reserves.

The origin of these life tables either here or abroad is difficult to trace. No reliable authority vouches for them. Even if an attempt were now made to ascertain the average service lives of the elements of the physical property, it would be extremely difficult to accomplish. If accomplished at all it would have to be revised constantly to correspond with the varying quality and service of the element. And, after all this continuing effort, we should have only the average lives, without any assurance that they would agree, even remotely, with the actual lives on any particular property.

While experienced engineers have recognized for many years that the use of the prevailing life tables must result in the accrual of excessive amounts in the depreciation reserve, an example of this result is afforded in the New York Telephone Company case, a decision on which was rendered Nov. 7, 1929, by three Federal judges sitting in the District Court for the Southern District of New York.

The court found, in effect, that the amount of the depreciation reserve was *prima facie* evidence of the extent of the actual depreciation, despite the contrary claim of the company and other evidence which had been accepted by the master. As this reserve was invested in the property included in the inventory and rate base, the net effect is that it was added in full to the reproduction cost new of the original property and deducted in full through depreciation of the entire property, leaving the rate base as the reproduction cost new of the original property, which is entirely equitable.

To sum up, the courts hold that only the actual depreciation should be deducted to arrive at a fair rate base, but it lies entirely within their discretion to find that the balance in the depreciation reserve is in fact the measure of the actual depreciation and that is what in general they may be expected to do. This was done in the New York Telephone Company case. But the District Court for the Northern District of Illinois, in its opinion in the Illinois Bell Telephone Company case on Jan. 31, 1930, took the contrary view. In this case, the reserve was $26,000,000, while the actual depreciation was found by the court to be about $14,500,000. The entire reserve had been collected from the rate payers and used by the company for extensions and additions to its property, and, in the opinion of the Illinois Commerce Commission, "the extensions and additions paid for from such moneys should not be considered, in arriving at a base upon which to compute rates for telephone service."

The statutory court reversed the commission, holding that the exclusion from the rate base of extensions and additions to the amount of $26,000,000 paid for from the depreciation reserve was clearly erroneous, that constitutional protection against confiscation does not depend on the source of the money used to purchase the property, that the revenue paid by the customers for service belongs to the company, and that the amount, if any, remaining after paying taxes and operating expenses, including the expenses of depreciation, is the company's compensation for the use of its property.

This opinion of the federal statutory court in Illinois appears to reflect the strictly legal view of the depreciation reserve as contrasted with the view taken by the similar court in New York which is in better line with the recent trend of opinion, and is more likely to prevail in future. In both the New York and the Illinois cases, the state commissions, like the court in New York, deducted the entire depreciation reserve to arrive at the rate base. In both cases, the reserve had been invested in the property included in the valuation inventory. It follows consistently that such part, if any, of the depreciation reserve as is in liquid form, such as cash, negotiable securities or other readily convertible property, should not be deducted from reproduction cost new in arriving at the rate base.

These principles are clearly enunciated by the courts, although, through lack of competent engineering evidence in the case, they sometimes fail to give effect to them in practice. The Supreme Court in the case of the United Railways & Electric Company, of Baltimore, Jan. 6, 1930, quoting from the Knoxville Water Company case, said:

> The utility is entitled to see that from earnings the value of the property invested is kept unimpaired, so that at the end of any given term of years the original investment remains as it was at the beginning.

We have just considered two properties in which the earnings permitted of accruing depreciation reserves double the actual depreciation as estimated by the engineers and the commissions.

Should actual depreciation be deducted to find the rate base in a property honestly and efficiently managed, but whose rates are so low as to prevent the accumulation of a reserve equal to the depreciation? That has been the experience of numerous public utility properties during the past ten years.

The Baltimore and Knoxville decisions logically determine that a deduction in excess of the reserve in fact collected from the rate payers is inequitable. Yet it is the almost universal practice to make some reduction for the actual depreciation, even when there is little or no reserve, and no claim of dishonest or inefficient management.

Normal Condition the Proper Standard

Ordinarily, a property comprised of numerous composite parts is in an abnormal condition when new, a condition experienced only once in its lifetime.

Hence the *reductio ad absurdum* of calculating actual depreciation as the relation of a normally operating property to its physical condition when new. Both sound economics and public policy require that the new property, intelligently maintained, repaired and restored, be worn down in the public service until it reaches its natural and normal physical condition, and that thenceforth it be kept as near as practicable to that condition.

Experience shows that the normal physical condition of well-operated public utility properties generally lies between 75 per cent and 95 per cent of new. It is highly desirable that engineers and regulatory bodies give special study to the determination, within narrow limits, of standard percentages for the proper normal condition of the several types of public utility properties, such as gas, light and power, railway, telephone, water-works. In a given case, there also would be found to what extent, if any, the particular property differed from the average, and its normal condition differed from the standard of its type. Then, for example, if it were found that an individual property whose normal condition should be 85 per cent of new was, in fact, five per cent below a first-class normal operating condition, its actual depreciation would be five per cent of 85 per cent, or 4¼ per cent, instead of 19¼ per cent, of reproduction cost new.

Digitized by Google

Now consider the example cited of a utility whose normal condition is 85 per cent, actual condition 80¾ per cent, and actual depreciation, therefore, 4¼ per cent. A reserve of 4¼ per cent is sufficient to restore it to first-class normal physical and operating condition. Suppose that, to avoid a deduction from fair value, it is required to have 19¼ per cent in the reserve. How can the excess 15 per cent be used in connection with the property whose integrity it is intended to secure? Of course, it can be invested in other property, or in securities. But it cannot be used as it was designed to be used, at least not for the decades or the generations that the property continues in public service. To do so would, in effect, involve the discarding of 15 per cent of property in normal condition and replacing it with new property, which, in due course, would assume the same normal condition, with no interim improvement in the service.

Although little emphasis is usually placed on obsolescence, and the courts and commissions treat it as an incidental part of depreciation, in the majority of public utilities it is, in fact, the greater part. Taking the term obsolescence to include inadequacy, change in the art, change in styles and in public taste, and all other similar contingencies, most of the elements of property are retired, not because of wear and tear and disintegration, but because of obsolescence. And obsolescence concededly cannot be measured by any age-life hypothesis.

There is an impression that obsolescence is likely to be a sudden or abrupt phenomenon requiring an immediate, or at least prompt, change in equipment. But generally there is ample notice of the impending changes, and an alert and efficient management usually can sense them years ahead. It is just a problem of intelligent care and prudent foresight.

Retirement for Economy

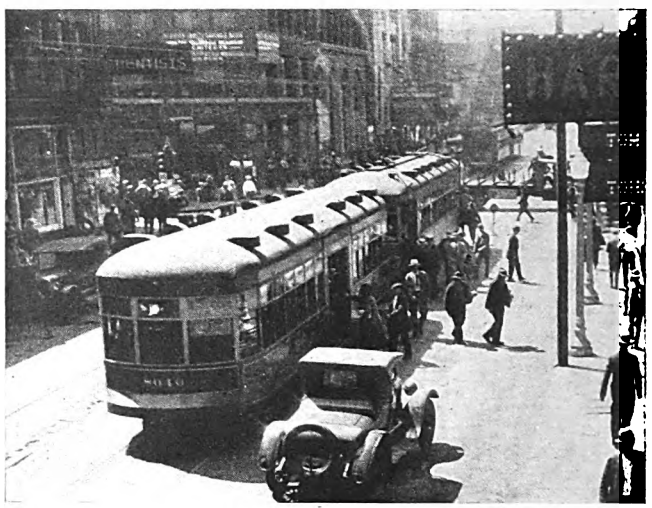
Past experience shows that a large part of the retirement results from reasons of economy. Whether units in excellent working condition are discarded because new types are more economical lies within the discretion of the management. If the expected economy justifies the change, and it can be financed, it should be made. The courts have ruled such matters to be within the rights of management. There now is a strong tendency to retire old street railway cars for reasons of aesthetics. Competition from automobiles renders it necessary to make the cars more attractive to patrons. Back of the idea of aesthetics is economy, as the net earnings would be increased by larger gross revenues due to attractive cars.

If the unit or equipment in question is of large value, a reserve should be built up gradually to smooth out the cost of its retirement when that becomes necessary or advisable, and the fund depleted by the several retirements as they occur. All this requires the exercise of good engineering and operating judgment. No possible formula can be substituted for this practical method. The amount accrued and written off at retirement should be the reproduction cost new of the equipment retired. Thus the utility will be credited with the actual cost of the equipment expressed in dollars of the time of its retirement and the investment kept intact.

The installation of new construction, plant or equipment, following retirement of the obsolete items of property, opens a new financial chapter. The capital account should be increased or diminished by the excess or deficiency in cost of the new items of equivalent capacity as compared with the reproduction cost new of those replaced. If the new items are of different capacity, a further proper adjustment should be made in the capital account. Any excess capital is, of course, furnished by the utility and not by the patrons. Any economies resulting from the new plant should be shared with the patrons, after providing a fair return to the utility and a depreciation reserve estimated and accrued in the manner heretofore described.

Trailer Operation Abandoned in Chicago

WITH the recent withdrawal of sixteen trailers from the Halsted Street line, the Chicago Surface Lines has suspended completely its car-and-trailer operation. Prior to this step, on July 18, the last trailers on Madison Street had been removed from service. Trailer service on this east-and-west artery was originally installed in 1923. Principal advantages to be gained from the change are: more frequent service, faster schedules, and greater flexibility in the use of equipment.



Car-and-trailer operation in Chicago which has been suspended to permit more frequent and faster service

Effective July 19, schedules were put into effect for single cars on Madison Street which practically doubled the frequency of service. During the rush hours, cars are now being run on a 60-second headway instead of a train every two minutes as on the previous schedule. In non-rush periods a car is dispatched every two minutes, instead of a train every 3¼ minutes. On night schedules, also, the frequency of service has been increased.

Speed of operation on Madison Street has been increased approximately 12 per cent with the single units. This additional speed has resulted in a saving of 5½ minutes to the passengers traveling from Austin Avenue to the Loop, a distance of 6.92 miles.

In all, a total of 100 trail cars are effected by the changes recently made. These trailers were purchased in 1921 and all are in excellent condition. As soon as funds are available they will be equipped with motors, control, compressors and other necessary apparatus, and placed in regular service on opposite routes. They have double center doors, but no end doors. With two-man operation it is believed that no additional entrance or exit facilities will be needed in certain classes of service.

Central Master Mechanics at the Dayton Country Club, where they enjoyed a luncheon given by the Ohmer Fare Register Company prior to being conducted through its plant

Central Master Mechanics Have Varied Program

COVERING a wide range of subjects pertaining to maintenance, the Central Electric Railway Master Mechanics Association, in convention at the Miami Hotel, Dayton, Ohio, on Sept. 10 and 11, spent a profitable two-day period. Among the topics discussed were modern braking, high-speed motors, transportation developments, motor maintenance, trolley buses, Youngstown cars, sand blasting, car wheels, safety methods, fire protection and journal boxes. A feature of the program was the showing of several sound pictures by E. S. Gunn, General Electric Company. The meetings, presided over by President A. J. Challeen, superintendent of equipment Eastern Michigan Railways, were attended by approximately 100 delegates.

Following the president's opening remarks, the members were welcomed by Mayor McDonald, Dayton; T. E. Howell, general manager City Railway, and Martin Ackerman, vice-president in charge of operation People's Railway.

The first paper, read by Lawrence Wilcox, Westinghouse Traction Brake Company, on "Modern Braking of Electric Railway Cars," was prepared by G. L. Cotter of the same company for the Cedar Point meeting of the C.E.R.A., and was abstracted in the August issue. The paper told of the factors affecting schedule speeds and the need for improving braking performance.

J. B. Corderman, Cincinnati & Lake Erie Railroad, described the modern braking equipment on the new cars of his company, and told of the resulting increase in schedule speeds and the greater safety factor. He also spoke of their maintenance.

In a paper on high-speed automotive type motors, prepared by R. S. Beers, General Electric Company, and presented by E. S. Gunn, of the same company, the weight-saving and other advantages were brought out. Mr. Beers compared the mechanical and electrical characteristics of these motors with the conventional slow-speed type, and related the results of the lighter motors in use on gas-electric buses, trolley buses and street cars.

A. B. Creelman, Youngstown Municipal Railway, described the thirteen new cars recently purchased by his company, and told of the results obtained from them. He cited a few of the troubles in the equipment that developed and explained how these were all remedied.

In the presentation of a paper, "Armature and Motor Maintenance," O. C. Wright, St. Louis Public Service Company, defined the term "maintenance" and outlined the basic principles for planning any successful program. He outlined the details which should be given especial care, and presented a complete program of tests and repairs. Mr. Wright described the tests and checks in the order in which they should be made and gave several valuable notes on the dipping, baking and handling of armatures.

In his address, "Recent Developments in Transportation," S. B. Cooper, Westinghouse Electric & Manufacturing Company, pointed out that four fundamental objectives in securing higher income or lower expenses, were being sought: reduced weight, lower floor and step heights, less noise, and faster service. The first three objectives, Mr. Cooper indicated, are largely influenced by the motor equipment, and the fourth by both motors and control. To obtain the full advantage of lighter and smaller motors, it was necessary, he added, to develop a form of gearing that would permit higher gear ratios, smaller wheels and a reduction of noise. Mr. Cooper showed how the WN drive had met the requirements satisfactorily, and gave figures on the life of these gear units. Other recent developments covered by Mr. Cooper included variable automatic control, trolley buses, and high-speed interurban cars.

Principles of Trolley Bus Maintenance

Developing the subject of trolley bus maintenance, Walter C. Becker, Chicago Surface Lines, outlined the basic principles of maintenance for street cars and motor buses, and pointed out that the trolley bus system must be based on all of these. Mr. Becker particularly emphasized the importance of a comprehensive maintenance system with fixed periods, based strictly on mileage, for servicing, inspection, repairing, unit replacement and overhauling. In concluding, Mr. Becker outlined definite procedures for daily inspection, lubrication, unit change and general inspection.

In a discussion which followed, concerning the use of the trolley shoe, E. J. Jonas, E. M. Lunda, A. J. Challeen, and G. R. Green, participated. The discussion was supplemented by reading a letter from J. H. Lucas, Milwaukee Electric Railway & Light Company, in which the results of polishing of trolley wire with graphite and using trolley shoes were given.

"Modern Sand Blasting" was the subject of a talk by C. T. Hertzsch, American Car & Foundry Company. The speaker described an effective but inexpensive sand-

Digitized by Google

blasting outfit, and told of the advantages and savings of installing one. Mr. Hertzsch also gave valuable pointers on selecting and conditioning sand, blasting thin sheets, maintaining the equipment, making adjustments and using primers.

An organized body, headed by a safety authority, to educate employees and obtain their interest, establishment of strict rules and enforcing them are necessary for maintaining a successful safety policy, according to F. H. Humphreys, American Car & Foundry Company. The speaker particularly urged the 100 per cent use of goggles, and cautioned that goggles of the correct type must be used. Mr. Humphreys pointed out that, aside from the humanitarian aspect, a safety campaign and use of modern devices result in enormous savings for the company.

G. E. Doke, president, Association of Manufacturers of Chilled Car Wheels, presented a paper, accompanied by pictures, on the history of the development of chilled tread wheels. Mr. Doke told of the research laboratory maintained, the careful inspection of plants, and the adoption of standard foundry practice specifications by the member plants. He also described the single-plate type of wheel and related its development and advantages.

"Carbon Dioxide Fire Protection" was the subject of a talk by H. B. Teter, of Walter Kidde & Company. The speaker described the new Lux standard extinguishers, explained the theory of how they snuff out fires, and listed the advantages of this type. The talk was supplemented by moving pictures, showing the effective use of these extinguishers in putting out various kinds of fires.

At this juncture in the program, moving pictures of the Central Master Mechanics being conducted through the Ohio Brass plant at Mansfield during their last meeting, were shown.

The next paper, "Maintenance of Truck Journal Boxes and Brake Rigging," by C. N. Pittenger, G. C. Kuhlman Car Company, was read by H. G. Arthur, of the same company. Mr. Pittenger showed how trucks are being affected by the severe operating and traffic demands of today, and pointed out various truck features which make renewals less frequent and less costly. Among the truck improvements, described by Mr. Pittenger, were wear plates in journal boxes, bushed half-ball brake hangers, bushed half-ball bolster guides, adjustable balancing hangers, automatic slack adjusters, and drop-forged pivotal plates.

Opinions on Several Topics Expressed

Discussion of the association's questionnaire brought forth the following conclusions: Metal is preferred to wood for sash in new car design; single side body sash is preferred to double for both city and interurban operation; opinion is divided on the use of wide-vision windows; automotive type high-pressure grease fittings are desirable for certain parts of truck and brake rigging, but unsatisfactory for others; pressed pedestal type seat supports are preferred to the open cast type; chromium plating is favored for the finish of corner grab handles on seat backs; anti-friction center plates, of the new design, with chromium plated ball bearings, are desirable for use; hard coal gives better results than coke for heating and is more economical; water alone is successful for washing cars with lacquer finish, if proper facilities are available, but certain compounds have been developed that assist in this work; use of low-viscosity oils has proved successful in lowering energy consumption.

Through the courtesy of the Cincinnati & Lake Erie Railroad the delegates were given a ride on one of the new high-speed interurban cars of that company. Approximately 45 enjoyed the trip to Middleton and return. At the banquet in the evening, the association was addressed by Judge R. W. Baggott, Dayton. Mr. Baggot reflected on our present modes of living, and discussed entertainingly certain of our present laws which are designed to mold our living habits.

Following the morning session of the second day, the delegates were tendered a luncheon at the Dayton Country Club by the Ohmer Fare Register Company. A feature of the luncheon was an informal address by John F. Ohmer, president of the company, who recalled many points of historic interest regarding the Central Association and presented a broad picture of the present rate question. Mr. Ohmer related the progress made so far, and told of the need for research and detailed analysis on the part of the railways. "Obtaining a scientific fare structure, to assure the most revenue, is largely a problem of studying requirements and educating the public," he concluded. In the afternoon the delegates were conducted through the Ohmer plant, and given an opportunity of studying its products and methods of manufacture.

The Readers' Forum

Street Car Interurbans

South Manchester, Conn., Sept. 14, 1930.

To the Editor:

During a recent trip through the West, I inspected an interurban of the modern type on which millions of dollars have been spent to make it the equivalent of a steam road electrification. But all these improvements seem to fall flat. People do not take it seriously as a railroad.

Now why is this de luxe interurban falling down? There are just four reasons for it:

1. Its steel cars are camouflaged to look like street cars; having street car bells and fenders.
2. Its trainmen are encouraged to believe they are "street car-ing" instead of "railroading."
3. Its motormen are forced to wear the crude old blue street railway uniform. Its management throws up its hands in horror at the idea of the motormen wearing overalls and jumpers.
4. In its advertisements it makes no reference to the railroad service it is giving, but rather uses the word "cars" throughout, which the riding public interprets to mean street cars.

So there you have a super street car line instead of an electric railroad, as it should be.

It is a pity that such interurbans do not realize the folly of imitating old-fashioned street car type interurbans in this modern day.

William H. Snow.
(Twenty years with the interurbans)

JOURNAL Maintenance Awards

Company trophy, individual cash prize and two certificates of merit go to Cleveland. Ottawa Electric Railway wins recognition in Department of Rolling Stock and Shops. Third period prizes announced.

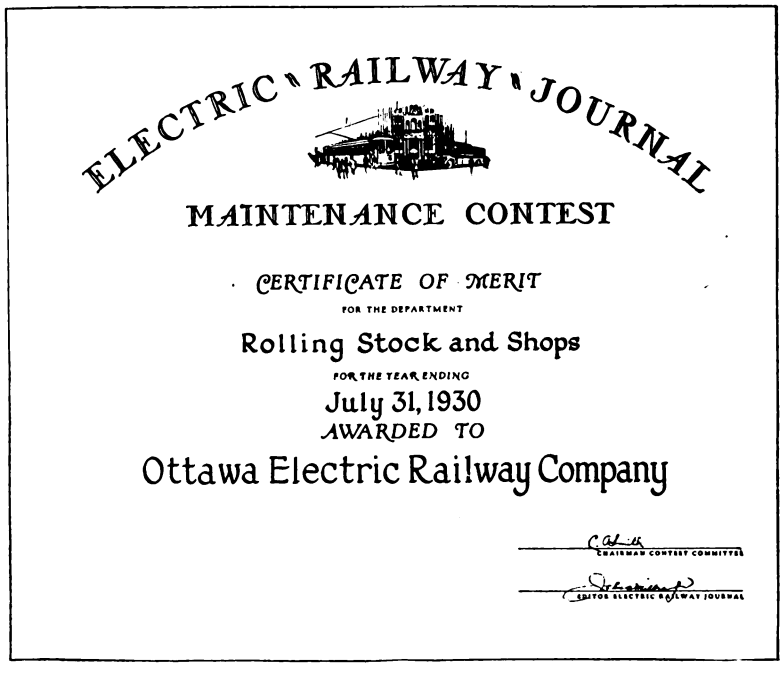
DUPLICATING its performance of a year ago, the Cleveland Railway won the company trophy in the ELECTRIC RAILWAY JOURNAL Maintenance Contest for the year ended July 31, 1930. The keen interest taken by the Cleveland Railway in this contest was shown by the large number of maintenance items submitted, exceeding by a wide margin the number submitted by any other company. Not only were the contributions of this railway numerous, but they also possessed considerable merit as shown by the number of quarterly prizes awarded to its representatives. In the first period of the contest two of the three prizes were won by Cleveland men. In the second period one prize went to Cleveland, and at the third period two were won by representatives of this company. One of the two prize-winning items in the first period was considered by the judges to be the most meritorious item submitted during the entire contest, and was awarded the individual cash prize of $100.

In the Departments of Way and Structures and Bus and Garages, the contributions from Cleveland were so outstanding that the company was awarded two certificates of merit. In the Department of Rolling Stock and Shops numerous excellent contributions were received from the Ottawa Electric Railway. One of these won the quarterly prize for the third period. In view of the keen interest shown by this company and the high quality of the material submitted, the judges unanimously agreed to award the certificate of merit in this department to the Ottawa Electric Railway.

After considering all the material submitted during the contest, the judges were unanimously of the opinion that the best single item was that submitted by Richard Grant, garage foreman, Cleveland Railway. This item, describing a double air chuck used to inflate dual tires, appeared in the March, 1930, issue of ELECTRIC RAILWAY JOURNAL, page 160. A few days before the publication of this item, the JOURNAL learned with keen regret of the death of Mr. Grant in an automobile accident. After consultation with officers of the Cleveland Railway, it has been arranged that the award be made to Mr. Grant's widow, Mrs. Florence Grant, of Lakewood, Ohio.

Richard Grant

AS THE result of injuries received in an automobile accident, Richard Grant died on Feb. 11, 1930, at the age of 39. His passing was keenly regretted by the Cleveland Railway and by all who had known and respected him for his pleasing personality and his admirable qualities as a man. Mr. Grant held the position of foreman of the Berea Garage for several years before his death, and under his leadership many new and improved shop practices were installed. During his association with the Cleveland Railway, which began in August, 1926, he frequently showed a great deal of ingenuity as typified in his contribution to the contest which won the capital individual prize. Mr. Grant is survived by his wife, Mrs. Florence Grant, Lakewood, Ohio.



Certificate of merit presented to Ottawa Electric Railway Company

Won by Cleveland Railway

Third Period Prizes Go to Ottawa and Cleveland

Leonard S. Rose

(In Oval)
J. Mondoux

William Anthony

AWARDS for the third period of the Maintenance Contest were divided between the Ottawa Electric Railway and the Cleveland Railway. In the Department of Rolling Stock and Shops the prize was given to J. Mondoux for his article describing a scheme to increase the life of truck jaws, as practiced in the shops of the Ottawa Railway. To William Anthony, general track foreman of the Cleveland Railway, was awarded the quarterly prize in the Department of Way and Structures for his entry entitled "Levelling Bar Facilitates Track Alignment." Both of these items appeared in the September issue of the JOURNAL. Another Cleveland Railway representative was awarded one of the prizes for his contribution in the Buses and Garage Department describing a connecting-rod boring tool. This item was submitted by Leonard S. Rose, assistant superintendent motor coach department, who has once before won a prize in this department.

For the second time in this contest, the judges were compelled to withhold the prize for the Electrical and Line Department because of the lack of deserving contributions. This situation should spur electrical men to increase their contributions in the next contest, beginning Nov. 1, 1930.

J. Mondoux

AFTER having served five years with the Engineering Corps of the Canadian Expeditionary Force in France, J. Mondoux returned to Canada in 1919 to join the repair department of the Ottawa Electric Railway. He has been in that department since, engaged principally in the repair and overhaul of car trucks and riggings. Recognizing that in no other department of an electric railway can an alert workman accomplish more to facilitate and improve the quality of workmanship by the development of ingenious devices and shop practices, Mr. Mondoux has always taken every opportunity to study shop methods with the hope of developing some new idea which would result in a saving of labor or cost. His efforts have often produced welcomed improvements, one of which is the scheme for lengthening the life of truck jaws, which is described in his winning contribution to the Maintenance Contest.

William Anthony

ATTRACTED by the opportunities to be obtained in a rapidly growing nation, William Anthony left his native land of Greece in 1908 as a youth of twenty, and arrived in the United States equipped with a sound training obtained at the College of Pojrogos. He mastered the English language in a short time. Mr. Anthony possesses the tenacity characteristic of his race. This tenacity has manifested itself through two decades of varied experience, finally bringing him to the Cleveland Railway as a sub-foreman and enabling him to advance to his present position of general track foreman in four months. His first opportunity was obtained with the Westinghouse Electric & Manufacturing Company with which he remained seven years to rise to the position of inspector of shells manufactured for the English Government during the first two years of the war. In 1916, Mr. Anthony became the employment agent for the Lorain Tube Mills, and it was with that company that he began his long association with track construction. Previous to his entering the employ of the Cleveland Railway, he had been track foreman of the Hunkin Conkey Company for one year, and held a similar position with the Lake Shore Electric Railway for six years.

Leonard S. Rose

WITH a background of wide experience in the field of maintenance of transportation equipment, Leonard S. Rose came to the Cleveland Railway in 1925 to assume the position of assistant superintendent of the motor coach department, in charge of maintenance. He was graduated from the School of Science and Technology of the Pratt Institute, and began his career as an inspector of substation construction with the Brooklyn Edison Company soon after graduation. Attracted to the automotive field, Mr. Rose became associated with the Packard Motor Company, which he served for seven years, five of which were spent in the capacity of technical service manager. In the following two years he filled the position of service manager in the New York State district for the White Company. His affiliation with the Cleveland Railway was preceded by a period with the Long Island Railroad as supervisor of maintenance of shop electrical equipment.

New Contest Begins Nov. 1!

Practical MAINTENANCE IDEAS

MANY ingenious devices and maintenance practices have been adopted by the Cleveland Railway. This company submitted a substantially larger number of items than any other railway in ELECTRIC RAILWAY JOURNAL Maintenance Contest ended July 31, 1930. On this and following pages are presented a variety of maintenance ideas developed by the company.

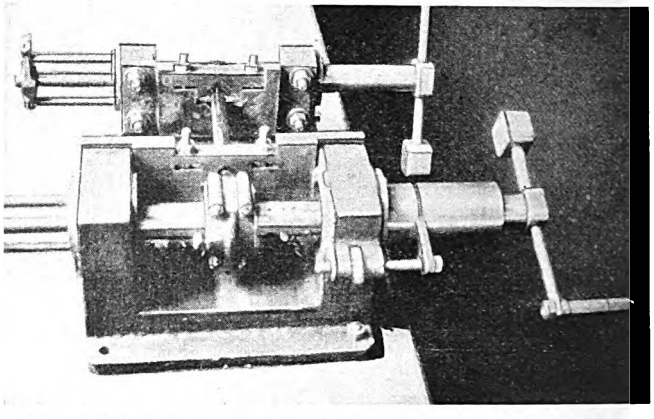
Connecting Rod Boring Tool*

BY L. ROSE
Cleveland Railway

FOR the repair and overhaul of connecting rods, the Cleveland Railway has designed a machine which is simple in operation and fast enough, in comparison with the customary shop method, to pay for itself in a short period of time. The machine consists of a body casting equipped with a sliding table. On both the body casting and sliding table are located V-type clamping plates so arranged as to permit considerable vertical adjustment and $\frac{1}{16}$-in. lateral adjustment. These V-plates are used to grip the connecting rods and are adjustable to take any standard size rod. Rods of varying lengths are accommodated by means of the sliding feature on the table. A constant length for each type rod is maintained by removable taper dowel pins through the table into the base.

Two special boring bars are used. Both bars are equipped with fly cutters and a square slot for the insertion of a two-blade Kelly reamer. The larger bar is also drilled for side cut-off in beveling tools. A large shoulder is provided on each of the bars so that cutters may be set to size and not disturbed by the removal of the bar during the boring of an entire set of rods. Provision for adjustment of side cut-off is had by means of a knurled nut and the guide which works in the groove of the large bar. This adjustment is disconnected when using fly cutters, and feed is accomplished by means of the 80 pitch screws pinned to the end of the cutter bars.

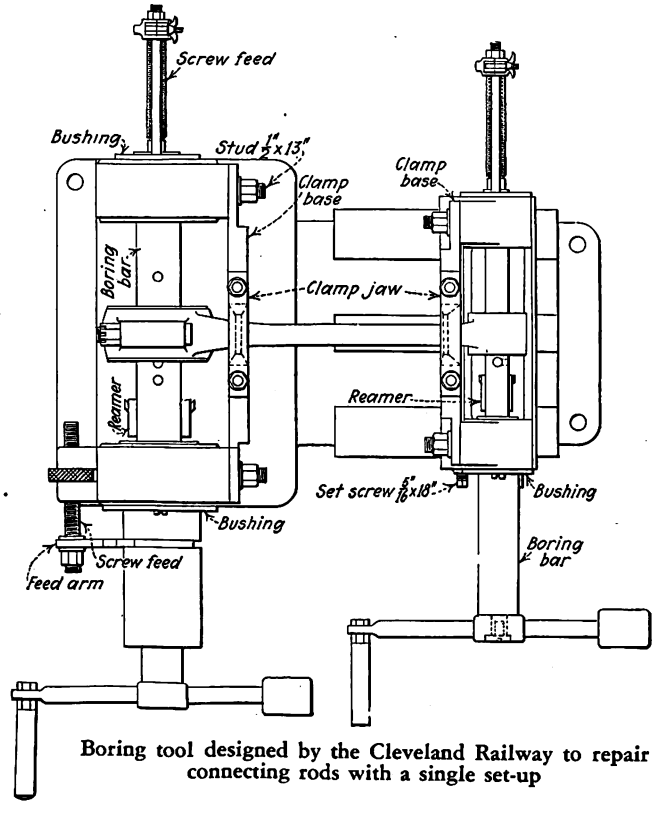
Initial location and mounting are obtained by the use of a Champion expansion mandrel which is mounted in the unbored wrist pin bushing. This centers the connecting rod in the sliding table and places it in a position at right angles to the wrist pin bushing. A height-controlling pin of a specified dimension for each type of rod is used under the larger end of the rod to locate the center accurately.



After initial adjustments have been made on this machine, an entire set of connecting rods can be bored without removal of bars

In overhauling a rod, the V blocks are disassembled, the slide adjusted to the predetermined setting and the proper height pin inserted in the base. After the rod is laid in the V, the expansion bushing is inserted and pulled up tightly. The rod is free to move laterally for centering with the large V plate. The plates are loosened so that they are free to move on the clamping nuts. The V is then tightened until a tight bearing is obtained on the rod, after which the clamping plate nuts are given a final tightening and the expansion mandrel is removed. The bar is then ready for boring.

The boring bars are next installed and through cuts to size are made in the regular manner. By using the reamers, both the rough and finishing cuts may be taken at the same time. This, however, requires accurate setting up and should be done only by skilled workmen. The amount of time involved in resetting the tool and making a finishing cut with a fly cutter after having taken the roughened cut is slight. After the bearings



Boring tool designed by the Cleveland Railway to repair connecting rods with a single set-up

*Submitted in ELECTRIC RAILWAY JOURNAL Prize Contest.

Digitized by Google

Developed by the Cleveland Railway

are bored, side cut-off tools are placed in the two holes provided in the larger bar and the sides of the babbitt bearing are faced and cut to the proper radius in the same operation.

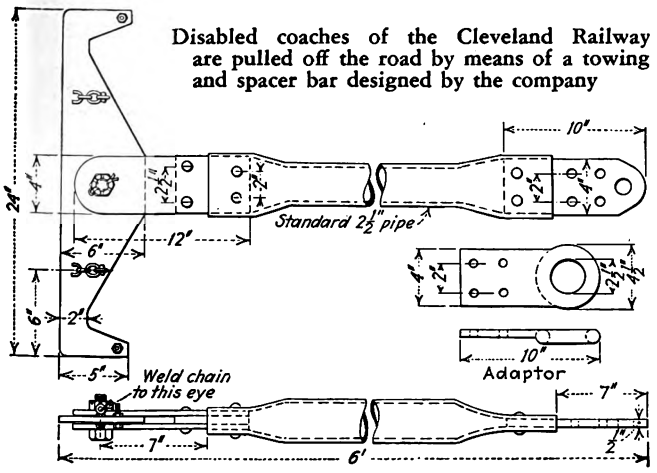
It has been found that the method of mounting described above gives practically no warping in the rod, so that the bearings which are bored parallel remain so after the rod is removed from the fixture. By clamping and boring in this manner it is not necessary to realign the bushings after machining operations have been completed.

Towing and Spacer Bar for Disabled Buses*

By William Piwonka
Engineer Cleveland Railway

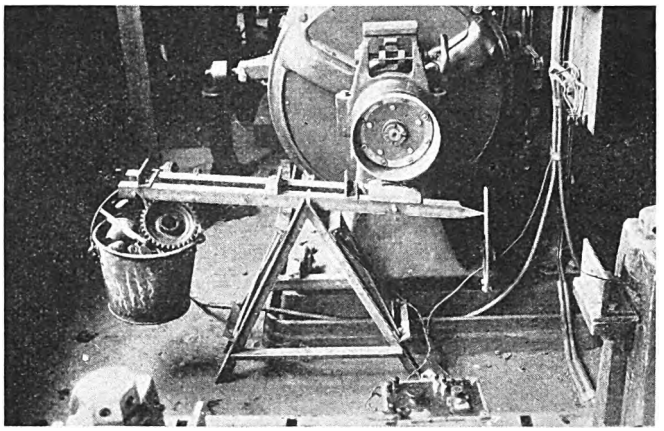
TOWING disabled coaches to their garages is of major importance where the disabled units must be removed from the road as rapidly and safely as possible. It is particularly difficult when the disabled coach is without brakes or is being run in on dummy wheels to protect a damaged rear axle. For this purpose a towing bar designed by the Cleveland Railway is being used with success. All garages of the railway will be equipped with them as standard emergency equipment.

One purpose of the design was to get a towing bar which could be rapidly and easily fastened to the bumper, front axle or front frame support member of a coach



Disabled coaches of the Cleveland Railway are pulled off the road by means of a towing and spacer bar designed by the company

or a truck. A small turning radius was also required together with a good factor of safety and ease of installation. Due to differences in the construction of various makes of coaches, the conventional clamping arrangement could not be used. To meet these requirements a pipe spacer bar is used. A swivel plate on one end is fastened to the front axle, bumper or front cross-member of the frame of the disabled vehicle by wrapping the two lengths of chain about the axle or bumper and securing them to bolts in each corner of the plate. The detachable adapter on the other end of the bar permits its use with all trucks owned by the company. No attempt was made to use the bar to steer the rear coach automatically.



Service conditions are simulated by this device for testing brake lining specimens

Brake Lining Selected by Test Results*

By Hoy Stevens
Superintendent of Maintenance Cleveland Railway

FACTORS influencing the service of brake lining for use on motor coaches have been carefully studied on the Cleveland Railway by supplementing the data obtained from actual service by laboratory tests and observations. In this manner, it has been possible to analyze the physical characteristics of the material and to judge what will happen under certain predetermined operating conditions.

The laboratory tests are made with an apparatus which consists of a brake drum mounted on one end of a dynamometer and a small stand equipped with a pivoted lever as shown in the illustration. The material to be tested is mounted on the pad which is at one end of the lever. Specimens 1 in. square are used and a thermocouple is inserted in a hole in the specimen to record the heat developed by the friction of material and brake drum. Pressure is applied by means of weights hung at one end of the lever with a 2:1 ratio of arms. In this manner, a 100 lb. weight will produce a pressure of 200 lb. per sq.in. on the brake drum when 1 sq.in. of lining is used as a test specimen. A pointer has been

Tests determine actual rate of wear of various linings

provided to indicate roughly the amount of wear, but it has been found desirable to measure this wear with a micrometer after the test is finished. Tests may be made for a large range of temperatures by regulating the flow of cooling water to a flange welded on the inside of the drum.

*Submitted in Electric Railway Journal Prize Contest.

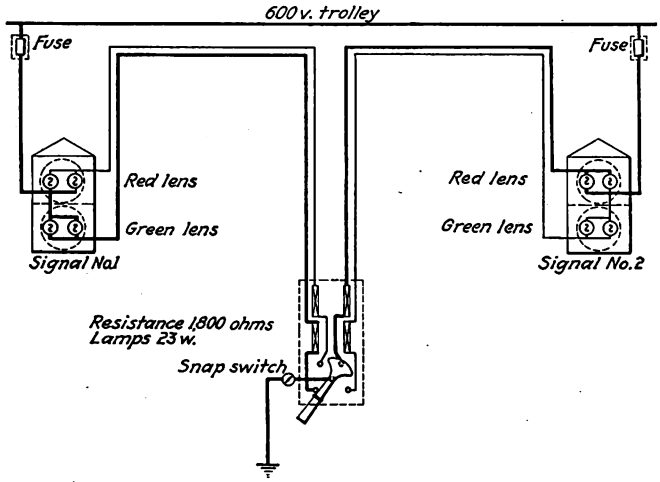
Digitized by Google

In testing the specimen, the coefficient of friction, and how it is affected by oil, grease or water, is determined at various temperatures. These qualities, together with the measured rate of wear, are important factors in the selection of brake lining material. For instance, in a coach where the brakes have a large factor of safety, so that the wheels can easily be locked by the operator, it may be advantageous to use a lining with a low coefficient of friction and thereby obtain greater life from the lining. On the other hand, where the braking ability is on the ragged edge it may be advisable to sacrifice lining life to increase the braking ability by using a material with a relatively high coefficient of friction.

Center Control for Temporary Block Signal*

By H. A. Brown
Foreman Return Circuit, Switch and Signal Division Cleveland Railway

WHEN cars are operated both ways on a single track during construction jobs, the Cleveland Railway uses a single center control block signal. The signal consists of a two-color light box at each end of the track section to be controlled, together with a three-position switch placed in the middle of the block and



Block signals manually operated by a flagman in the center of the block protect tracks during construction on the Cleveland Railway lines

operated manually by a flagman. The arrangement of circuits is shown in the accompanying diagram.

By throwing the switch to the right, a red light is displayed at one end of the block, and a green light at the other. When the switch is thrown to the left, the colors of the lights at the two ends of the block are reversed. By placing the switch in the center position, red lights are displayed at both ends of the block, enabling the flagman to control car movements if trouble occurs within the signalized area. A snap switch permits opening the circuit when the blocks are not in service.

The signals are simple and portable, so that two men may install a complete set in five hours. They replace the old methods, in which two or three men acted as flagmen, or block signals were manually operated at the end of the block by the car crews, or automatic signals were installed for use with trolley contactors.

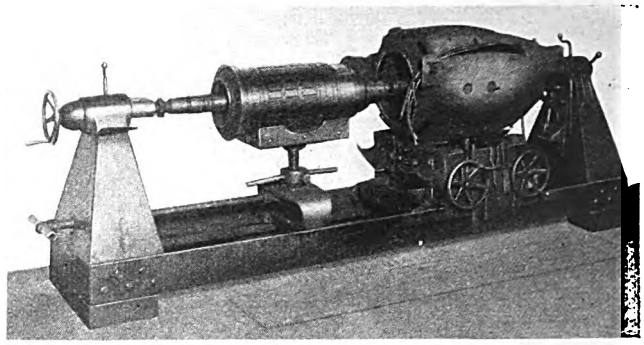
Convenient Machine for Armature Removal*

By Terance Scullin
Superintendent Buildings and Equipment Cleveland Railway



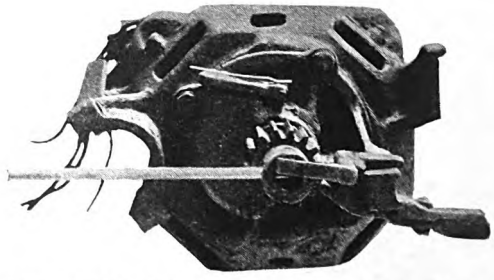
One-man machine which removes armatures from box-frame motors

ARMATURES are removed quickly and easily from motors by means of a special machine at the Harvard Shops of the Cleveland Railway. It consists of a bed with supports at both ends to hold the armature and motor box in center. Two cradles are provided, one for the motor box and another for the armature. A square thread elevator with lever attachment is used for raising and lowering the armature to and from the position of centering. The motor is placed on the motor cradle and centered. By means of two wheels the motor cradle is raised and lowered to the desired position. The motor box frame is then carried off on to the long arm of the machine and the armature cradle brought into position to receive the armature. Only one man is required for the operation.

Dog Holds Armature Pinion*

By M. J. Leary
Assistant Superintendent Buildings and Equipment Cleveland Railway

REMOVAL or tightening of the nut holding the motor pinions on the armature shaft has been facilitated greatly by tools made at the Harvard shops of the Cleveland Railway. A special tool, shown in the illustration, is placed on the gearcase bracket after the pinion wrench has been put on the nut. The device works like a ratchet, allowing shorter bites to be taken. The device keeps the wrench from slipping off the nut, and obviates any danger of the workman's being injured. Only one man is necessary to remove or replace the pinion nut. Pre-



Ratchet dogs developed in Cleveland permit one man to remove or tighten pinion nuts without chance of injury

Digitized by Google

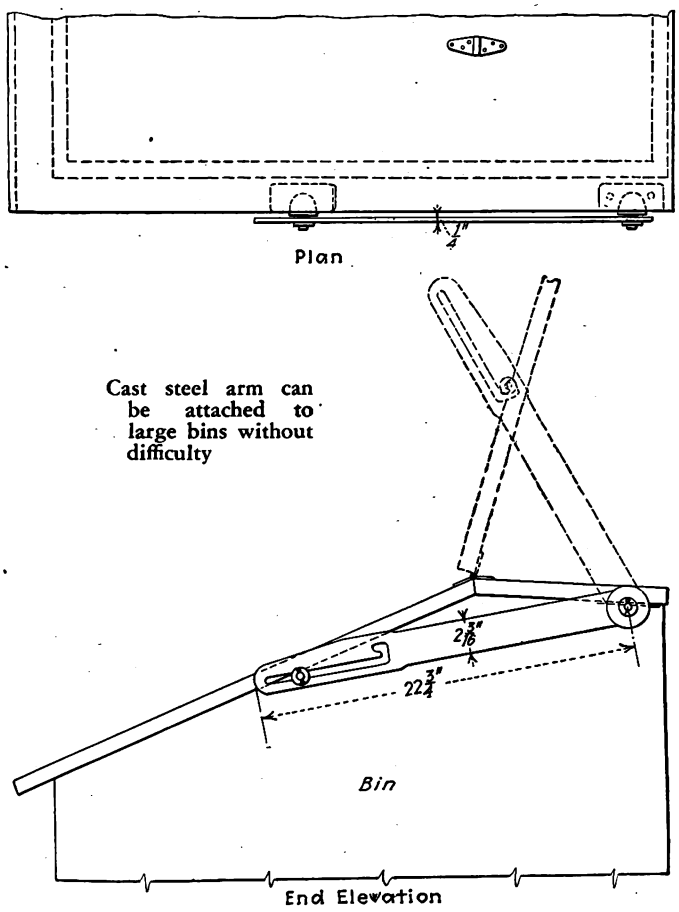
viously, an ordinary pinion nut wrench was used, pressure being placed on it by means of a long bar. One man held the bar, while another tried to keep the wrench from slipping off. This method was awkward. Frequently the wrench would slip off, and the bar would fall on a man and injure him. Both right and left-hand dogs are made up, so that they can be used for loosening or tightening the pinion nuts. The cost of the two is approximately $5.

Safety Arm for Coal and Sand Bin Lids*

By Joseph App
Mechanical Department Cleveland Railway

SAND and coal supply bins are located at the ends of the various lines of the Cleveland Railway. These boxes have large heavy lids which, when opened, rest in an almost vertical position against an upright on the back of the box. A sudden wind has on several occasions slammed this lid shut, injuring a trainman.

To prevent the unexpected slamming of these lids, a safety arm has been designed which locks them open. It

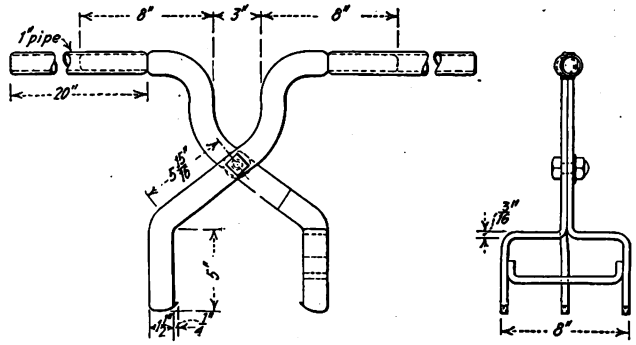


Cast steel arm can be attached to large bins without difficulty

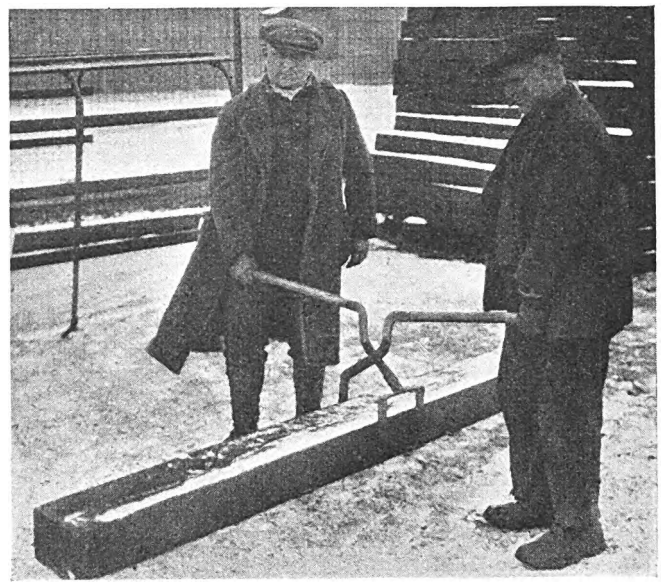
consists of a steel casting, $22\frac{3}{4}$x$2\frac{1}{2}$x$\frac{1}{4}$ in. with an 8-in. L-shaped slot near one end. The slot allows free movement of a pivot of cast steel which is fastened to the lid. The other end is pivoted at the side and near the back of the box. When the lid is raised the lid pivot slides back to the foot of the L-slot to a depression which locks the lid securely in the open position. To shut the lid, it is necessary only to work the pivot back into the slide by a slight movement of the lid.

Treated Ties Safely Handled*

By R. B. Evans
Assistant Superintendent of Construction Cleveland Railway



Three point grip is obtained without penetrating below the treated depth of tie



Tongs enable two men to handle tie with ease and affords greater protection against skin irritation

GREATER facility in the handling of ties has been obtained on the Cleveland Railway by the use of tongs which have been cheaply made in the shop. The tongs have three prongs, two of which grip the tie on one side and the third on the opposite side, making it easy for two men to balance the weight. The tongs are made of cold-rolled steel, and are joined at the pivot point by a $\frac{5}{8}$-in. bolt. The handles are of ordinary 1-in. wrought-iron pipe to which the ends of the tongs are forged and welded. The wood is gripped by stub points which do not enter far enough to pass through the treated zone and yet they are sufficiently deep to permit a firm grip without danger of the tie slipping from the tong.

The use of this tool has materially speeded up the handling of treated ties and has made it possible for two men to handle them with safety. Another advantage in the handling of treated ties with tongs lies in reducing the danger of sore eyes and skin irritations caused by contact with the creosote.

The danger of skin irritation to men handling ties in a storage yard is a serious one and one which affects to a large extent the speed with which ties may be piled. By greatly reducing this danger the men will go about the work with a greater freedom of action.

This device holds a motor shell in position for boring out the axle bearing seats

Simplified Boring of Motor Axle Bearing Seats*

By John Greer
Assistant Foreman Mechanical Department
Cleveland Railway

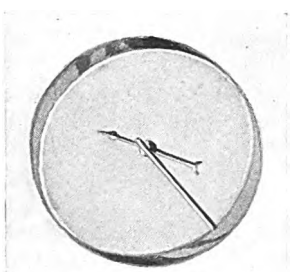
SAVING of nearly four-fifths of the time required to set up a motor shell for boring out the axle bearing seats was accomplished by a jig designed and built in the Harvard Shops of the Cleveland Railway. The jig consists of a bedplate and two sliding vertical ends. The latter have holes spaced the same as those in the ends of the motor shell for attachment of the end housings.

After the motor frame has been built up by welding it is lifted in place by means of a crane and bolted to the jig. It is then ready for the reboring after 2½ hours work, whereas by the old method 12 hours were necessary. The cost of the jig was $55.

Two-faced Compass Determines Motor Field Polarity*

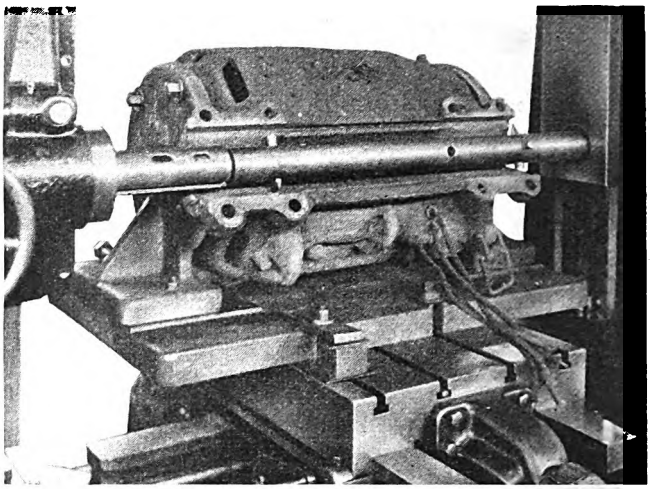
By R. Dumke
Foreman Mechanical Department
Cleveland Railway

POLARITY of motor fields is tested at the Harvard shops of the Cleveland Railway by a specially constructed compass. When the field polarity of the motors of a car over the pit must be determined, the simplest method is by means of an ordinary compass. As there



Compass with glass on both sides makes it easy to determine motor field polarity in Cleveland Railway shops

is only one open face it is difficult and, in some positions, impossible to see the compass. The special compass was made with glass on both faces, so that it can be viewed from any angle. The center spindle which supports the needle is held in place by a single narrow brace soldered to the rim.

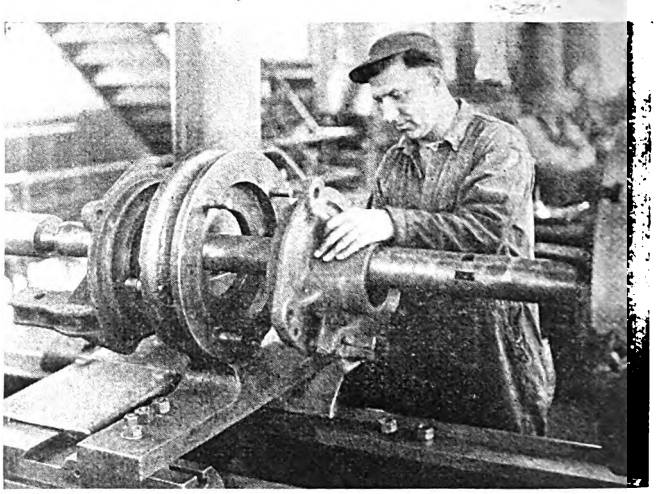


A motor in place ready for boring in the jig designed by the Cleveland Railway

Oversize Bearing Housings Bored in Jig*

By Martin F. Niederst
Foreman Mechanical Department
Cleveland Railway

FOR boring armature bearing housings which have become worn in service, and in which oversize bearings must be used, the Cleveland Railway has designed and built a jig, which is used in the Harvard shops.



By use of a special jig developed by the Cleveland Railway two end housings may be bored at once

The jig consists essentially of a ring with studs located in positions similar to those of the motor shell, so that the housings for the two ends of the motor can be bored out at once, thus insuring that the bearings will be in line.

Use of the jig saves considerable time in making the set-up, and since under the old method the housings were bored one at a time it was difficult to line up the bearings. In addition, the method saves considerable time and labor. The cost of the jig was about $35.

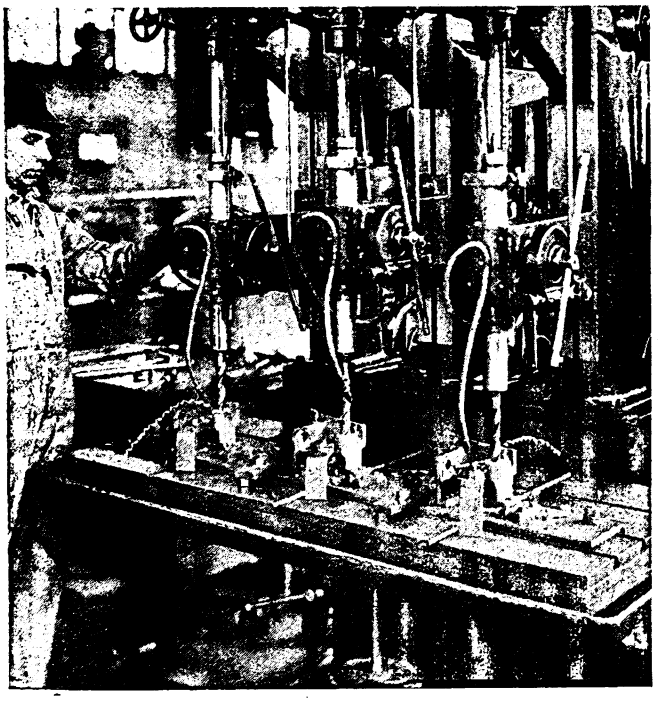
Ingenious Jig Speeds Brake Head Drilling*

By Martin F. Niederst
Foreman Mechanical Department
Cleveland Railway

BRAKE heads are drilled at the Harvard shops of the Cleveland Railway in an ingenious jig developed by the mechanical department. This jig comprises a set of clamps so arranged that three brake heads can be placed in position for immediate drilling. A workman can insert one brake head in the first space of the jig and start this drill; then he can do the same for the other



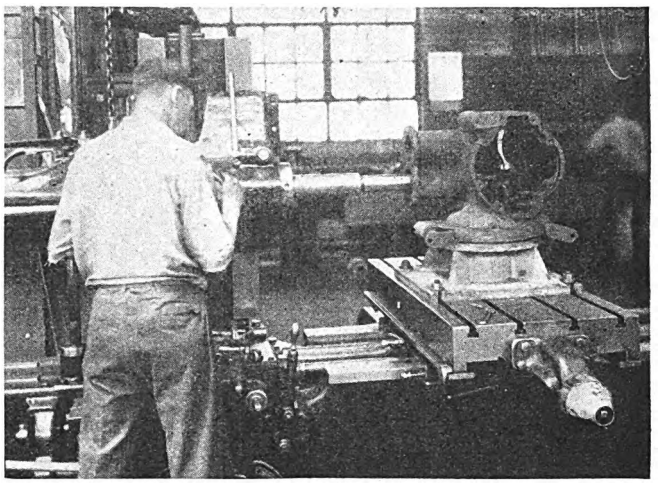
Three brake heads are drilled progressively in one jig in the Cleveland Railway shops

two drills in turn. By the time the third head is clamped in place the first one is completed and he can start over again with drill number one. In this manner he is able to drill brake heads continuously. With the aid of this jig, one man can do three times the work done under the old method of drilling. The approximate cost of one of these jigs is $12.50.

Cylinder Boring Device for Air Compressor*

By Ray C. Sohl
Chief Engineer Cleveland Railway

FOR boring worn cylinders of air compressors, which are to be rebrushed, a jig has been designed and built at the Harvard shops of the Cleveland Railway. It consists of a short cylindrical casting, the face plate of which has holes drilled in the same relative positions as those on the compressor body casting. The latter is bolted in place on the jig, and is held securely in position. The base plate of the milling machine is fitted with



Milling machine fitted with jig to facilitate boring of compressor cylinders

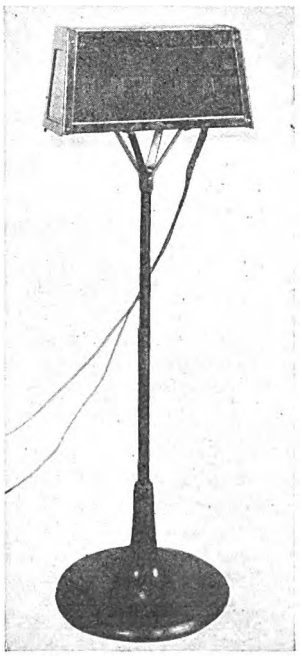
keyways and locations for the studs to hold the jig firmly in position.

By means of this jig the boring can be done more accurately, and, at the same time, handling is reduced to a minimum.

Blinker Light Protects Linemen on Night Work*

By Christ Reinker
General Foreman Mechanical Department
Cleveland Railway

PROTECTION of linemen while working at night on the Cleveland Railway system is afforded by a blinker light designed and built in the shops. A sheet metal hood fitted with red glass is supported on a telescopic pipe stand with a heavy cast iron base. With a series of holes and a key, the light may be set at any desired height, or the stand may be collapsed into a small space for transportation on the truck. Five 110-volt, 23-watt Mazda lamps are connected in series, one socket being fitted with a Diamond flasher button. This device can be lighted directly from the trolley, and with its flashing red light is an effective warning to approaching traffic. The hood is inclosed on the top and four sides, so that it is entirely weatherproof. The bottom is open, affording good ventilation and making replacement of burned-out lamps an easy matter. While simple in design, the appearance is attractive. The lamps and stand are readily portable. It cost about $7 to make.



Linemen in Cleveland are protected by this flasher which shows an intermittent red light

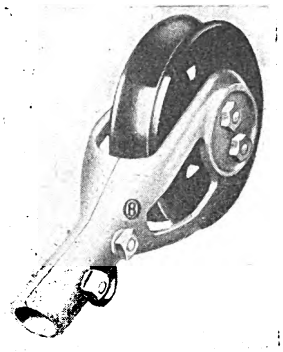
NEW PRODUCTS for the Railways' Use

Trolley Wheel Lubricated With Composition Washer

IMPROVED lubrication with adequate current capacity is incorporated in the improved trolley wheel made by the Ohio Brass Company, Mansfield, Ohio. A washer of a composition of copper and graphite is now used in place of the fiber washer between the ends of the hub and the harp. The new washer is a conductor of electricity, whereas that formerly used acted as an insulator.

Most of the current now passes from the hub to the harp through the washer instead of through the



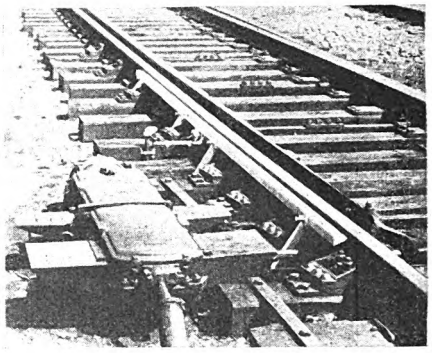
Lubricating washers conduct current around axle from trolley wheel hub to harp

axle, thus eliminating the possibility of pitting the axle. In addition to its conducting quality, this new washer acts as a lubricant, reducing wear and, to a large extent, eliminating end play in the wheel.

The harp is designed to protect the flanges of the wheel from damage when a flying trolley pole strikes a cross span or bridge structure.

Switch Heater Supplied With Gas Fuel

SWITCH heaters for melting snow and ice, using gas as fuel and ignited from one central point, have been recently announced by the Chausse Oil Burner Company of Elkhart, Ind. The gas, either artificial or natural, can be turned on and ignited from one point, such as a signal tower. This eliminates all manual requirements for starting switch heaters and offers a centrally controlled equipment which can be operated at a low cost.



Remote control of igniter and fuel supply is an attractive feature of new switch heater

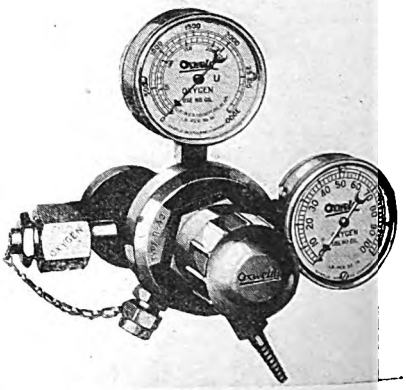
The switch heaters are 14 ft. long, placed close to the ball of the rail, and are held in position by substantial malleable-iron clamps which are attached to the ties. Gas is admitted at the center of the heater and distributed through a specially designed combustion chamber. Practically no flame is visible and consequently there is no interference with low switch targets. An igniter of michrome wire wound on a lava spool is attached at the center in a substantial steel housing and connected with the central operating switch. These heaters normally consume about 75 cu.ft. of gas per hour and the igniter is rated at 220 watts. During severe storms the heater can be left turned on constantly at a very low expense, or it can be left on for a few minutes in starting and then periodically switched on by the tower man. The rail is kept at a temperature well above the melting point of snow and ice but not sufficiently hot to affect its texture. Actually, there is sufficient heat rising above the track to melt the snow before it reaches the rail and consequently there is a path, a foot wide, on each side of the rail free of snow. The heat is sufficient to prevent accumulation of ice, and at times will keep clear the entire area between the rails. It can be successfully used on remote control crossings provided there is a source of domestic gas near by.

Pressure Regulator for Oxy-Acetylene Apparatus

FREEDOM from fluctuation of acetylene gas pressure is obtained by means of a two-stage pressure reduction device recently introduced by the Oxweld Acetylene Company. This two-stage reduction is accomplished through two separate and independent sets of diaphragms, valves and springs. The full cylinder pressure of 2,000 lb. enters the regulator through a stem-type valve and is controlled by the first stage diaphragm. In this stage, the pressure is reduced to less than 250 lb. per sq.in. This pressure will be constant for any one regulator, but varies somewhat with different regulators. The pressure here is non-adjustable.

The oxygen then passes from this first reduction assembly to a second stem-type valve and a diaphragm assembly where the pressure is reduced to the working pressure desired by the operator. This pressure is regulated by the operator by means of the adjusting screw.

Instead of the usual handle-type pressure-adjusting screw found on all other Oxweld regulators, there



Oxygen regulator equipped with a gage for tank pressure and a gage for working pressure

has been substituted a screw with a ribbed cap. The claim for this change in external design is not only a neater and more compact appearance, but also the avoidance of possibility of breakage as there are no projections on the handle to be bent accidentally. This new type adjusting screw is of smaller diameter than the body of the regulator itself, so that it is easier to pack for moving.

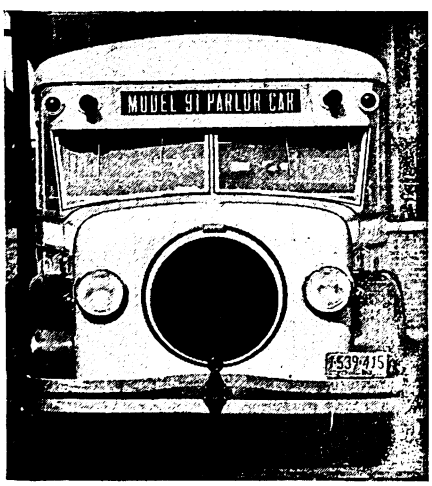
The new Fargo bus has been designed for compactness and speed. The power plant extends within the body and the driver sits at the left of the engine

Fargo 8-Cylinder Bus Placed on Market

RADICAL departures from standard construction are found in two new models just brought out by the Fargo Motor Corporation of Detroit. the recently organized bus and truck division of the Chrysler Corporation. While these units are to take the place of the former Dodge line of buses, and incorporate some of the features contained in it, they represent an entirely new design.

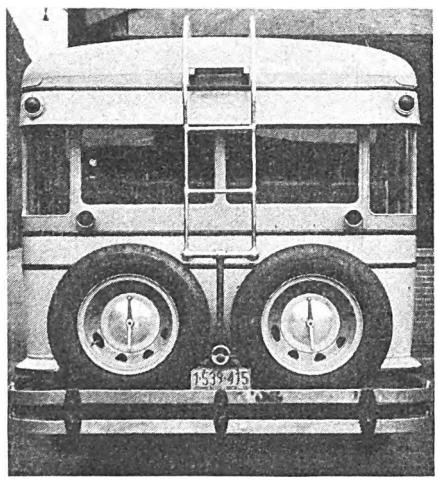
Perhaps the most striking change is the appearance of the front, which has been so shaped as to reduce wind resistance. The hood is shortened and has been rounded, with a gradual taper to meet the side panels. The windshield is tilted to meet the curve of the roof. The same body and chassis are used for a parlor car type and a city service type bus. The two, however, have different finish and appointments.



A broad, curved hood and inclined windshield have been adopted to reduce wind resistance

The engine is an 8-cylinder, L-head model, adapted for bus service from the Chrysler Imperial engine. It is mounted on a chassis built with 10x$\frac{3}{16}$-in. hot-rolled steel channels, with six cross members. Specifications of the engine and equipment are given in an accompanying table.

On account of the shortened hood the power plant has been extended backward within the body. The driver's seat has been placed alongside the engine, and the steering wheel is mounted well forward on the frame. All controls, except the horn button, which is on the steering post, are on the dash directly in front of the driver. A door in the dash gives access to the engine from inside the body, while hoods at the front can be raised to uncover the fan, generator and belt drive.

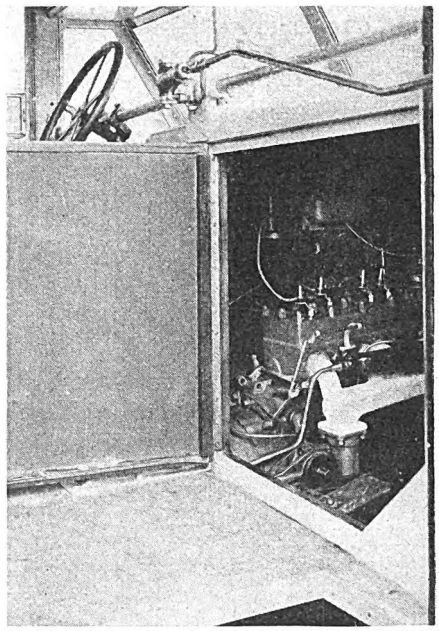


The depressed baggage space on top is reached by a substantial ladder

An unusual feature is that by taking off the hood, uncoupling the universal joint, gear shift lever and control wires, only four caps surrounding the lugs on the engine need be removed so that the engine can be slid forward on supporting rails and lifted from the chassis by a crane.

Moving the driver forward gives 20 in. additional length inside the body for passengers and permits wider spacing of seats, particularly at the wheelhouse. Being at the extreme left, the driver is in a better position for driving in traffic and there is more room for passenger movement in and out of the bus.

Two distinct bodies are included in the line. The parlor car has seats for 21 passengers, with four additional aisle seats available. The interior finish is modernistic, the motif being carried throughout. An overhead baggage rack extends the length of the bus on either side. An aluminum alloy rail at the edge acts as a hand rail. In addition, there is an outside luggage loft recessed into the roof, which is reached by a ladder at the back end.



Accessibility to the engine is obtained by a door at the right of the driver's seat. The entire power plant can also be slid forward readily and removed with a crane

The city type bus also has 21 seats, but they are spaced on 29½-in. centers to provide greater standing room, making it possible to carry a considerably greater rush-hour load than usual. Doors are of the double jackknife type, folding inward. A rear exit door is placed behind the rear axle. Both doors are operated by

Brooklyn, N. Y. — The Brooklyn & Queens Transit Corporation, after successful operation of trolley buses, has filed a petition for extension of the Cortelyou Road line through Flatbush section to New Utrecht Avenue.

✦

Albany, Ore.—Rails will be laid on the new Oregon Electric extension east of Lebanon before 1931, W. F. Turner, president, and A. J. Witchell, chief engineer of the Spokane, Portland & Seattle and Oregon Electric railroads, said on Sept. 17 before leaving for Portland following an inspection trip over the new construction work.

✦

Camden, N. J.—New records were established for carrying bus passengers to seashore resorts in the Southern division, Public Service Co-ordinated Transport, over the Labor Day week-end. More than 35,000 passengers were hauled without an accident.

(Late News Continued on Page 656)

Additional Time Needed for Toledo Grant Revamping

Negotiations looking to a revamping of the Milner service-at-cost ordinance in Toledo, Ohio, have reached a deadlock. The board of street railway control has indicated that sufficient time is not available in which to go over the franchise carefully, and recommends renewal of the Milner grant for two years. Provisions for such renewal are contained in the ordinance.

Company officials have suggested that the Community Traction Company be awarded an exclusive franchise for the rest of the time under the present grant, and have offered in exchange flexible fare provisions to give school children a 5-cent fare, permit or weekly passes and other special fares designed to stimulate riding.

Board of control members recommended several fundamental changes in a letter to Mayor W. T. Jackson on April 24. They suggested scaling down the capital value because of the $2,500,000 abandonments, refinancing of preferred stock at 7 per cent, a change to make the sinking fund dependent upon earnings rather than a recapture of capital as claimed at present, power to the board to authorize extensions of bus service, and authority for the commissioner to approve all contracts. The board sees no way out of the $812,000 accrued debt due to the deficit in the stabilizing fund, on which no interest is being charged for ten years.

August Earnings Off

Three steps are open to the city in the matter now: (1) Renewal for any period up to ten years; (2) substitution of a remodeled ordinance; (3) amortization of the property over the next fifteen years as provided by the present ordinance. Renewal could be considered later during this amortization period. To renew or revamp the ordinance requires a vote of the electors.

Total revenue of the Community Traction Company, Toledo, Ohio, in August was $215,358, the lowest point reached for several years. This represented a drop of about $80,000 under the similar month of last year. Operating costs were reduced about $29,000. After all charges in keeping with the Milner ordinance, the deficit charged to the stabilizing fund was $63,003. All individual car lines showed losses but two of the bus lines showed a slight profit. The new Maumee Valley belt line showed a slight loss. The railway ratio of expense to operating revenue was 88.418 per cent and the coach ratio 96.977 per cent. In first eight months in Toledo 28,969,941 passengers were carried compared with 36,232,810 for the similar period last year.

COMING MEETINGS

Sept. 29-Oct. 4—National Safety Council Convention, Pittsburgh.

Oct. 6-11—Sixth International Road Congress, Washington.

Oct. 9-11 — Midwest Electric Railway Association, Miami, Okla.

Oct. 22-24—National Transportation Meeting of the Society of Automotive Engineers, Pittsburgh, Pa.

Oct. 29-30—Iowa Electric Railway Association, Des Moines, Iowa.

Nov. 12-15—National Association of Railroad and Public Utility Commissioners, annual meeting, Charleston, S. C.

Ticket Plan in Effect a Year in St. Louis

Results of the first year of the use of weekly commutation tickets by the St. Louis Public Service Company show that the average fare for ticket riders was only 7½ cents or less than the prevailing rate of fare when the ticket system was put into effect in August, 1929.

During the year more than 7,500,000 tickets were sold and an average of fifteen rides was taken on each ticket. The total rides, including 5-cent fares of ticket riders, were 115,928,699.

When the ticket plan went into effect on Aug. 26, 1929, the first twelve rides were 90 cents and each additional ride in any week 5 cents. After eighteen weeks trial, the cost of tickets was raised to $1 with extra rides at 5 cents. During the year 27,000,000 5-cent rides were taken by ticket holders, or an average of 3.52 rides per ticket sold. The progress of the plan through the years has been recorded in the JOURNAL from time to time.

Supreme Court Refuses Kansas City Fare Stay

Chief Justice Hughes at Washington, D. C., on Sept. 20 refused to issue an order restraining the Kansas City Public Service Company from putting into effect an increase from 8 to 10 cents in fares. Final determination of the case awaits an appeal now pending before the court. The Kansas City Public Service Company succeeded in having a higher schedule of rates approved by the Public Service Commission of Missouri. The city took the case to a Circuit Court, which issued a temporary restraining order. The company appealed to the Supreme Court of Missouri, which held that the Circuit Court had no jurisdiction. The case was appealed, but in the meantime the city, through Marty K. Brown, Jr., sought the stay.

LATE NEWS

(Continued from Page 655)

Toledo, Ohio—The Community Traction Company has rerouted its Maumee Valley line, an interurban coach loop, so that it will abandon the Miami Street feeder line on the east side and transfer part of the operation of the Beverly feeder line to take in a new territory in Heather Downs district.

✦

Philadelphia, Pa. — Business men of South Philadelphia have now informed William S. Vare that unless the City Council appropriates funds to extend the Broad Street subway to navy yard they will take part in a "rebellion" against the Republican organization. Mr. Vare assures them that the project has his personal approval.

✦

Birmingham, Ala. — By agreement with the city, the Birmingham Electric Company will substitute buses for its street railway line from Woodlawn to Irondale. The city agreed to the change in order to obtain the electric company's right-of-way for a paved highway. Transfers will be issued on the bus line without charge. The Birmingham Electric operates only one other bus line, the Avenue F line.

✦

Louisville, Ky.—The Louisville Railway is arranging to operate more one-man cars. The Preston, Main and Eighteenth Street line, and the Portland and Shelby Street line, using double-truck two-man cars, were to go to single operator methods, the former on Sept. 18, and the latter on Oct. 5. In addition, one-man cars were to be placed in operation after 6:30 each evening on the Bardstown Road, the Second Street and the Market Street lines.

✦

New York, N. Y.—It is not regarded as likely that any statement on the Interborough Rapid Transit Company's policy on unification will be issued until after the organization meeting of the new board of directors, Sept. 30.

✦

St. Louis, Mo. — The taxable valuations of Missouri public utilities have been increased $10,905,453 by the State Tax Commission. The new total is $504,613,191 compared with $493,770,738 fixed by the State Board of Equalization in 1929. Street and electric railways are valued at $62,756,086, compared with $61,802,001. The utilities may appear before the board between Sept. 17 and 26 to protect their valuations.

✦

Richmond, Va. — The Virginia State Corporation Commission has taken under advisement the complaint of citizens of Petersburg and Hopewell that additional bus service should be rendered by the Southside Transportation Company. The Petersburg, Hopewell & City Point Electric Railway is opposing the proposal to extend the bus service.

✦

New York, N. Y.—Thomas I. Parkinson has been renominated by directors of Manhattan Railway to succeed himself on the board of directors of the Interborough Rapid Transit Company for a term of three years, as a representative of the Manhattan Railway.

Wheeling, W. Va.—Trainmen of the Wheeling Traction Company have defeated a proposal of a six-day working week, three to one. The plan was set forth simultaneously with the announcement of a schedule change by the railway which cut one run from the Martins Ferry-Rayland division and sheared one from the Barton division after 6:45 p.m. Trainmen are now working eight days and resting the ninth.

✦

Seattle, Wash.—No further transfers to the Seattle & Rainier Valley Railway line will be issued Sundays to children who ride the cars and buses of the Municipal Railway on school tokens. Sunday school cards and fares will be accepted as usual, however. The Sunday transfer privileges for all children of school age were arranged between the two systems for the duration of the school vacation period only.

✦

Memphis, Tenn.—The Memphis Street Railway has offered to Mayor Overton and the City Commission a bus line from Poplar and Cooper, out Poplar to Highland Street, down Highland to Central, in Central, past the new Fairview High School, to East Parkway, down the Parkway to Young Avenue, on Young to Cooper, and north to the starting point. Buses would run both ways all day, with extra buses during school hours. Fare would be 10 cents, with a transfer to any of the five street car lines free, and 3 cents when transferring from a street car to a bus. The company did not ask for a franchise but for an opportunity to try out the new service.

✦

New York, N. Y.—The Interborough Rapid Transit Company has served notice on the Transit Commission that it will ask the Supreme Court to set aside an order issued on Sept. 4 requiring the company to show cause why a mandamus order should not be issued compelling it to obey the Transit Commission's demand that it purchase 289 new cars and extend station platforms at Spring and Canal Streets on east side line.

✦

Baltimore, Md. — Smoking is being permitted on the new cars of the United Railways & Electric Company. And a cigar maker has replied to this concession by advertising that the particular kind of rope sold previously by him at 10 cents has been reduced to 5 cents for each length. Which has reminded one commentator of Shakespeare's immortal words: "Ingratitude, thou marble-hearted friend."

You Will Want to Tune In

ON Wednesday evening, Oct. 1, Old Counselor, speaking for Halsey, Stuart & Company, will broadcast a talk on the electric railways, over the National Broadcasting chain of 37 stations.

Philadelphia, Pa.—Probably the largest suburban station in the United States for electrified train operation will be opened here on Sept. 28 by the Pennsylvania Railroad. It will be located under the city's new Broad Street Station Building at Sixteenth Street and Pennsylvania Boulevard. The new station will accommodate all of the railroad's suburban service operating in and out of Philadelphia, involving a total of 325 electric trains daily. These trains now use Broad Street Station. Approximately 30,000 Philadelphia commuters will use the new facilities daily.

✦

Oklahoma City, Okla.—Rejection of the Oklahoma Railway's unofficial offer to remove its belt line embankment from Northwest Park if the city would pay for the work has been ordered by the city park board, members of which said they believed the Council had no right to grant a right-of-way on property dedicated for park purposes without the board's consent.

✦

Vancouver, B. C.—Despite fewer passengers carried by the British Columbia Electric Railway for the year ended June 30, the total revenue from the passenger transportation system shows a slight increase over that of last year. The greatest decrease is shown in the freight business of the company. Much of the revenue from this branch results from the interchange with various transcontinental systems, and the drop shown in freight traffic of these systems is reflected in B. C. Electric returns. Depression in the lumber industry also contributed to the decline.

✦

Columbus, Ohio—The Columbus Railway, Power & Light Company has asked the Public Utilities Commission for permission to abandon its lines to Minerva Park. A hearing is set for Oct. 28. The commission authorized the company to discontinue service on the line from Minerva Park to Westerville in December. The petition states that for fifteen years the company has suffered large annual deficits as the result of the service. The company is willing to start bus service to Minerva Park from the north corporation line on Cleveland Avenue.

✦

Philadelphia, Pa.—Dr. A. A. Mitten, president of Mitten Management, has contributed to the September issue of *Executives Service Bulletin*, published by the Metropolitan Life Insurance Company, an article in which he describes the background of his organization's recent comprehensive survey of Philadelphia traffic conditions and the measures which were recommended for their relief.

✦

Newark, N. J.—A radio receiving set and a refrigerator are features of the equipment of a new, luxuriously appointed motor coach completed in the Newark shops of Public Service Coordinated Transport for use in its special and chartered bus service. The new coach has the same chassis and the same modern body design as the company's new super-service type buses, but it is equipped with swivel chairs, upholstered in richly colored velour. A special glass-inclosed compartment has also been built around the operator's seat to insure greater privacy for the passengers.

Montreal Tramway to Help Defray Tunnel Cost

The Montreal Tramways, Montreal Que., has agree to pay one-third of the cost of the proposed $2,500,000 tunnel beneath Lachine Canal at Wellington Street. The city will approach the federal government immediately to obtain government assistance in the cost of construction. It is hoped that a referendum may be submitted before the end of November.

The Wellington Street tunnel would replace the bridge which now carries street railway lines and vehicular traffic over the canal. Traffic is particularly heavy at this point, and the tunnel would provide direct and easy access to Verdun and other sections of the city across the Lachine Canal.

At the meeting of the city representatives, the Montreal Tramways Commission and the Montreal Tramways, a similar tunnel to cross the canal in Cote St. Paul was also considered favorably, but the project will not be pressed for the present.

New Rates in Washington Benefit Railways

A. G. Neal, comptroller of the Washington Railway & Electric Company, says the operating report of the company for July has been misconstrued. According to the figures actually reported to the Public Utilities Commission, a decrease of 78 per cent in income is shown for July, 1930, over July, 1929. Mr. Neal explained, however, that a difference in crediting a rental item would make the decrease only 30 per cent over July of last year.

Utility experts who have examined the July operating report of the Capital Traction Company have expressed the opinion that, as in the case of the Washington Railway & Electric Company, bookkeeping methods make the decline in income over July, 1929, seem more than is actually the case. The net income of the Capital Traction Company for July is about 50 per cent below the corresponding month last year, it is stated, instead of 78 per cent as indicated by the figures.

Despite the losses in income which have resulted mainly from unrestricted taxicab completition, the inreased rates in Washington have benefited the railways. It is estimated that the companies are taking in approximately $1,000 more a day than they would have received had the old rates prevailed. From reports filed at the commission, it is shown that the 35-cent flat fare cabs are losing money. The announced intention of the commission to regulate cabs is expected to have a salutary effect in reducing the number of these vehicles.

Novel Merchandising Plan Conducted in Cincinnati

"SAVE half enough to buy your evening theater tickets by riding street cars. This is R.K.O. month." With this text, an interesting co-operative advertising plan was developed in Cincinnati during August by six Radio-Keith-Orpheum theaters and the Cincinnati Street Railway. The plan was developed through a desire on the part of the amusement people to advance the normal opening of the theater season from Sept. 1 to Aug. 1, and on the part of the railway to promote greater use of street cars in the evening.

Bills of exceptional merit were arranged at all the R.K.O. theaters. Large three-color posters, 22x28 in., were carried on all street cars, featuring the theaters and the railway service. These posters showed a strip of car tickets in one corner and a bunch of theater tickets in the opposite lower corner. The poster read, "Save by riding street cars—see more shows." Posters inside the cars carried usual street car messages. These included a special corner postscript advertisement, emphasized in red, calling further attention to the use of street cars for attending evening theaters. The back of the Sunday pass for Aug. 17 was also used for the plan.

The price of admission for evening shows ranges from 30 cents to 50 cents. With the usual charge for parking of 30 cents to 50 cents and the cost of driving a car, it was shown to be possible to save at least the cost of one ticket by using the street car.

In return for the advertising carried on the street cars, the R.K.O. Corporation carried in all of its houses a two-minute news reel, featuring the advantages of street car service for attending the theater. The street car film opened with the announcement, "Cincinnati's street cars spring a new one, observing R.K.O. month," and then showed familiar street scenes with the company's street cars in service. Other captions in the film were: "There are 350,000 car riders daily," "Shoppers leave early for return to evening shows," and "R.K.O. theaters are conveniently located near car lines."

The six R.K.O. theaters give eight shows daily with an estimated attendance of 2,000 persons each performance. This means that the film was favorably presented 336 times during the week before an estimated audience of 672,000 people. Details of the plan were developed by William E. Danziger, of the R.K.O. Corporation, Hudson Biery, director of public relations of the Cincinnati Street Railway, and Clarence E. Runey, motion picture producer.

The news film showed many points of interest in Cincinnati and featured the operation of street cars. In addition three-color posters, 22x28 in., were carried on the dash of the street cars during the campaign

Bondholders Oppose Receiver's Certificates to Meet Expenses

Proposals by Elmer W. Stout, receiver of the Terre Haute, Indianapolis & Eastern Traction Company and three leased lines, to give operating expenses preference over mortgage bond obligations were opposed on Sept. 15 by attorneys for the bondholders at a hearing before Judge Joseph M. Milner of the State Superior Court in Indianapolis.

The three lines involved are the Indianapolis & Martinsville Rapid Transit Company, the Indianapolis & Northwestern Traction Company and the Indianapolis, Crawfordsville & Danville Electric Railway, having an aggregate trackage of 164 miles.

The bondholders' attorneys announced opposition to any course which would tend to reduce the equities of the bondholders in the properties, declaring bondholders agreed with the suggestion of the Midland United Company, which recently offered to purchase the bonds of the T.H.I.&E., that operation of the leased lines should be discontinued at once.

On Aug. 20, the Midland United Company, an Insull holding company, made a subsequent offer to the bondholders' committees of the three leased companies, agreeing to purchase the first mortgage bonds at about 20 per cent of face value, or a price equivalent to the salvage value of the lines plus the value of the power business conducted by them. The bonds have been selling on the open market for from 10 to 15 cents on the dollar.

On Sept. 5, Mr. Stout, the receiver for the T.H.I.&E., filed a report with the court, announcing his decision not to continue operation of the three leased lines as part of the T.H.I.&E. receivership, because of deficits in operation. Two days later, Mr. Stout was appointed receiver for each of the three companies.

On Sept. 13, the receiver asked the court for permission to borrow money from the receivership fund of the T.H.I.&E. which would become a prior lien to first mortgage obligations in order to pay deficits and continue operation of the three separate lines. This served to force the issue of whether it would be to their bondholders' advantage to continue the lines with money obtained from warrants superior to their first mortgage rights. Mr. Stout knew of no way to finance the operation other than through receiver's certificates.

Judge Milner has taken the petition under advisement.

Omaha to Vote on Bridge Bond Issue

At the November election to be held in Omaha, Neb., the citizens will vote on the question of issuing bonds for erecting a free bridge between Omaha and Council Bluffs, Iowa, to take the place of the present toll bridge owned and operated by the Omaha & Council Bluffs Street Railway.

If the decision is favorable for the free bridge, it will be a virtual repudiation of the gift by the railway of its bridge under an escrow agreement whereby the two cities are to receive the bridge free as soon as the company's price of $4,155,296 is received in tolls. The estimated time for realizing this price is 6½ years from date of the gift, Oct. 31, 1929. This time has now been cut to 5 years and 9 months.

Under the escrow agreement, the title to the bridge is being held by six Omaha and Council Bluffs men and cannot be revoked by the railway. However, the agreement provides that it will automatically be revoked if construction of a new bridge is begun within a mile of the present structure (the only logical place for a new bridge), or if condemnation proceedings are started against the present bridge.

The free bridge advocates consider the company's price of $4,155,296 for the bridge too high.

Improvement Bonds for Chicago "L" Approved

The Chicago Rapid Transit Company has been authorized by the Illinois Commerce Commission to issue $7,160,000 in two-year gold notes to provide funds for improvements. The notes are to be sold for not less than 96 per cent of par and are to bear interest not in excess of 6 per cent. They may be retired before maturity on 30 days' notice. The present plan is to refund this indebtedness when the surface and the elevated lines are consolidated. In the plea to the commission to issue the notes, the company made it plain that approval of the issue would enable improvements to be started at once, made necessary by the new franchise settlement ordinance.

Well-Rounded Program for Miami Mid-West Meeting

An elaborate program of papers and an inclusive carnival of entertainment for both the delegates and the ladies have been arranged for the annual meeting of the Midwest Electric Railway Association at Miami, Okla., on Oct. 9, 10 and 11. The program of papers follows:

OCT. 9

10 a.m.—"Welcome to Miami"—Rev. Willmore Kendall, introduced by W. L. Rush, Mayor of Miami.

Response — President H. S. Robertson, president Denver Tramway.

"The Trackless Trolley"—F. M. Peters, district manager, transportation department, General Electric Company, Chicago.

12:30 p.m.—Round table luncheon.

2:30 p.m.—"Small-City Operation"—F. J. Johnson, railway engineer St. Joseph Railway, Light, Heat & Power Company.

First aid demonstration—NEO team.

Address—J. F. Owens, vice-president and general manager Oklahoma Gas & Electric Company.

6:30 p.m.—Banquet, Rockdale Country Club.

Address—W. L. Crittenden, chairman speakers bureau Oklahoma Utilities Association.

OCT. 10

9:30 a.m. — "Electric Transportation Equipment for Present Day Operating Requirements"—S. B. Cooper, manager, general engineering department, Westinghouse Company, East Pittsburgh, Pa.

"Manufacturers' Hour" — Five-minute talks by supply representatives on developments, or on any other matter of interest.

12:30 p.m.—Round table luncheon.

2:30 p.m.—Joint session with Mid-West Claims Association.

"Solicited Claims"—G. T. Hellmuth, general claims attorney Chicago, North Shore & Milwaukee Railroad.

Address, "This Road Is Not Foolproof"—John E. Curtis, former chairman Nebraska State Railway Commission.

For hotel reservations write to H. B. Cobban, general manager of the Northeast Oklahoma Railway, Miami, Okla.

Consideration of Service-at-Cost Grant Postponed

Portland's service-at-cost franchise as proposed by the city's consulting engineers, Carey & Harlan, has been tabled and no part of the several ramifications of it requiring acquiescence of the voters of the Oregon city will appear on the ballot at the November election. This was the decision of the City Council after a second hearing on the proposed franchise on Sept. 16.

Reasons advanced by the Council for not attempting to whip the ordinance into shape at this time so as to be able to place it before the people in November were: (1) that there is insufficient time between now and election to inform the people fully as to the proposed provisions; (2) that if the proposition should be placed on the November ballot it would become a football of political controversy with the effect of obscuring the economic issues involved.

Counter proposals offered were, first, that the city offer the company $1 for tracks and pavements instead of $3,900,000 suggested in the Carey & Harlan plan, and second, that a straight 5-cent carfare be placed in effect with the city reimbursing the company out of taxes for such losses as would inevitably occur.

The next hearing on the ordinance is scheduled for Nov. 15. In the meantime it is expected that a settlement of present difficulties may be effected at informal conferences between the city's engineers and officers of the company so that the final franchise presented to the people for approval will be one that the company can accept. It is possible that the franchise may be presented before the people at some special election next year.

Baltimore Revenue Off 8.12 Per Cent in August

Revenue passengers of the United Railways & Electric Company of Baltimore declined 17.39 per cent as compared with August, 1929, according to Lucius S. Storrs, president. This is in proportion very close to the decline for this August of all the railroads in the eastern territory, so that it may be said to reflect pretty accurately the depressed business conditions and unemployment in the section.

The United's decline in gross receipts was considerably less than that of other companies, Mr. Storrs said, being only 8.12 per cent as compared with August of last year. This was due to the fare increase granted early in the year. The decline in revenue passengers this August was not due alone to depressed business conditions, but reflected also the effects of the extremely hot weather.

The final showing of the company under all circumstances is good, the president declared. The net income declined only $15,291.64 as compared with August, 1929, reflecting economies along all lines which the management was able to put into effect without interfering with the service, with decline in car-miles of only 5.29 per cent. Condensed operating figures are given in the monthly statistics on page 643 of this issue.

It is pointed out that the net result is that the United shows a smaller decrease in earnings than any railway in the country serving a comparable population where an increase of fare has not taken place.

Large suburban station to be opened in Philadelphia.

Tunnel expenditure approved for Montreal.

Jacksonville still at work on new franchise.

More one-man lines for Louisville.

President Storrs explains Baltimore August figures.

Effective merchandising stunt in Cincinnati.

Electric railways subject of broadcast Oct. 1.

Ticket plan in St. Louis on trial one year.

Portland plan to be considered later.

Many attractive papers on Mid-West program.

Washington companies benefit by new rate.

Smoking permitted on Baltimore's new cars.

Parking and Garage Problem Studied at Washington, D. C.

Believing that the automobile terminal problem challenges the best constructive efforts of those who are responsible for community development; that it can be solved economically and effectively only on the basis of adequate facts, and that henceforth building and city planning must take cognizance of the implications of the parking and garage problem if serious consequences are to be avoided, the Automobile Parking Committee at Washington, D. C., has completed an extensive engineering survey on this subject, and submitted a detailed report of its findings, together with definite conclusions and recommendations.

The technical work for this committee was conducted by the staff of the National Capital Park and Planning Commission, under the supervision of Charles W. Eliot, 2d, director of planning for the commission. Dr. Miller McClintock, director of the Albert Russell Erskine Bureau of Harvard University, consultant to the commission, organized the survey, analyzed materials, and drafted the formal conclusions and recommendations.

Facts about the central business district developed by the survey revealed that future development of governmental areas, and a more intensive use of commercial land areas within the central district will greatly increase the automobile terminal problem. An analysis indicated that the demand for parking exceeds the effective supply of such facilities, and that additional provision must be made if this form of transportation is to develop. The relation of parking to business and to the transportation of government employees was carefully analyzed. It was definitely determined that parking regulations should be based on business needs, with as great liberality as is consistent with necessary freedom of movement and equitable provision of available facilities.

A summary of the general recommendations submitted by the committee follows:

Angle parking should be eliminated, as the 25 per cent reduction in capacity on the few streets where it is now permitted will be more than compensated for by greater regularity of parking and traffic movement.

The provision permitting double parking should be repealed, and a strict prohibition substituted. Loading zones should be freely established with a special provision that they may be occupied by waiting private cars in charge of a driver, when the zone is not required for loading or unloading.

One-hour parking limits should be continued in the congested districts as defined in the official regulations. One-hour limits should also be applied to any business district in the city.

A two-hour parking limit should be applied in the district immediately surrounding the present congested districts.

Within a period of two years all-night parking at any place in the city should be prohibited.

To reduce the number of all-day parkers it is recommended that parking be prohibited between 8 and 9:30 a.m. in the more congested part of the business area.

The final conclusions arrived at as a result of this survey are as follows:

It is safe to say that the eventual solution of the parking problem is not to be found along the streets, and, indeed, present conditions are such as to warrant immediate attention to alternative and more efficient terminal facilities.

While parking restrictions or prohibitions beyond those reasonably required for current use should not be used to force abnormal garage construction, a definite indication of the willingness to apply reasonable restrictions and a recognition of the ultimate need to prohibit when traffic requirements justify, should have a very stimulating effect upon private garage enterprises.

Provision of garage facilities through the self-contained block plan should in no manner discourage individual property owners from the construction of commercial garages, or the builders of office or other buildings from evolving plans to incorporate garage facilities as an integral part of their structures.

No structure should be built in downtown Washington without adequate provision for the off-street handling of commercial movement.

Garage facilities should be provided for storage space of approximately 1,000 cars in each of five buildings composing the triangle group of Federal buildings.

If the proposed garage construction is undertaken, rates should be adequate to cover operating charges.

The Business Outlook

A MAD week from start to finish, mad with alarms, plots and rumors, governmental and private, brought into play or used by professional bears as a final desperate resort to squeeze the last drop of profit out of the short side of financial and commodity markets. This sort of thing is usual in the last stage of deflation, when prices have discounted all possible further business decline and are beginning to respond to the forces of recovery. Such forces are obviously though still feebly at work, but the rate of improvement is too slow to warrant expectation of return to normal levels in the few remaining months of this year, without more vigorous Federal Reserve action and militant business leadership.

—*The Business Week.*

Two Ohio Lines Suspend

Two of Toledo's oldest interurbans, the Toledo, Bowling Green & Southern and the Toledo, Fostoria & Findlay will cease operation on Oct. 1 under authority granted by the Ohio Public Utilities Commission. On application of the Cleveland Trust Company, trustee, C. C. Fernsell, Dover, has been named receiver for the Toledo, Fostoria & Findlay line. Service on this road was stopped for a day when the Lake Erie Power Company, supplying energy for a section of the line shut off the power because of an unpaid bill of $5,000. Representatives of the Western Ohio Railway & Power Company, said the abandonment of the T.F.&F. line would force the Western Ohio lines out of business. The latter connects Piqua, Lima and Findlay.

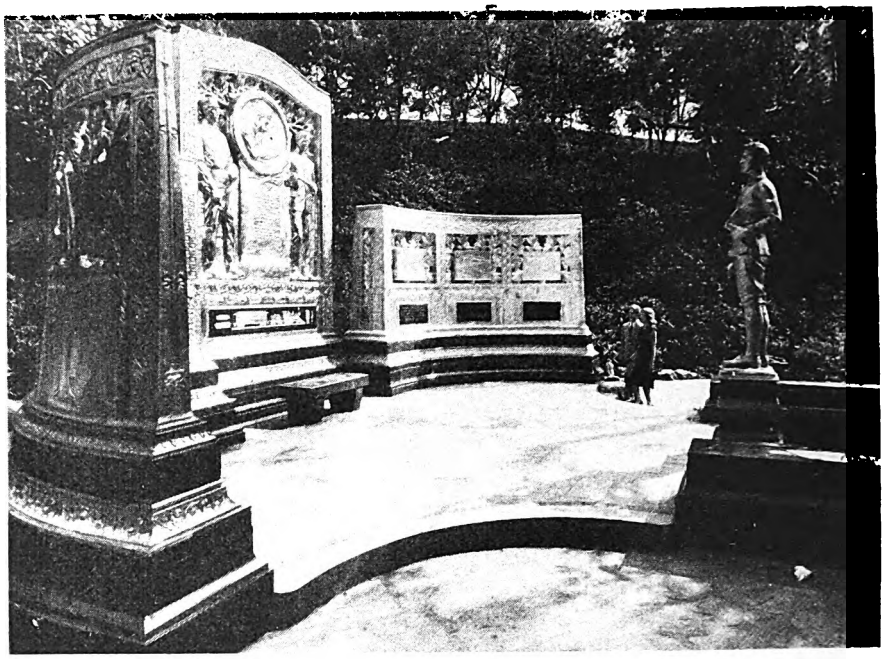
Memorial to Be Dedicated Oct. 6 to Westinghouse

Dedication of the memorial to George Westinghouse, inventor and founder of the vast industries which bear his name, will take place on Oct. 6. Invitations are now being sent to leaders of industry, science, art and education to attend the dedication as guests of honor and pay tribute to the genius who conceived the air brake, developed the steam turbine and was the proponent of alternating current, and, as well, created industrial structures to provide the world with the benefits of these vital engineering developments.

The ceremony will include the dedication and unveiling of a bronze group of heroic proportions created by Daniel Chester French, America's foremost sculptor. A banquet will be tendered to the invited guests in the evening.

The construction of the memorial and its dedication is in charge of a board of trustees consisting of the men who captain the Westinghouse industries. Erection of the memorial was made possible by appropriation and subscriptions among 60,000 employees of Westinghouse industries in the United States and other countries. Its location will be the most beautiful spot of Schenley Park, Pittsburgh.

Mr. French created the center unit of the memorial and the companion piece—the American youth. Henry Hornbostel designed the setting for the memorial. The Piccarelli brothers constructed the models of the various units for casting. Paul Fjeldi designed the six panels depicting the great achievements of Mr. Westinghouse The main unit rises 20 ft. from a Norwegian granite base. It includes a dominating figure of Mr. Westinghouse in the prime of his life. Flanking him are two figures depicting a skilled workman and an engineer typical of the thousands of artisans who assisted the master in his work. Facing this group on a separate pedestal is a figure of American youth modeled in an inspired attitude as he studies the monument of achievement.



Memorial to memory of George Westinghouse in Schenley Park

Balanced Development Needed for Rapid Transit

The planning of future rapid transit lines so as to create, in the more open areas of New York City, important new business and residential centers entirely independent of the congested midtown Manhattan sections, is urged by the Regional Plan of New York in a report made public on Sept. 27. Decentralization, brought about by transit, zoning and planning, is seen as the only means of avoiding overbuilding and the stifling of circulation in the old centers.

This report, on the relation between building bulks and transit, covers one of a series of studies being prepared by the Regional Plan staff as part of the final volume of its surveys of the metropolitan New York region, which have been under way during the past seven years.

The report points out that the construction of new transit lines to the already overcrowded centers, instead of relieving the congestion in these centers, would "add to the congestion by giving new facilities to extend and maintain it." By utilizing new lines to build up undeveloped parts of the city, however, public authorities would promote balanced development.

LATE NEWS

(*Continued from Page* 656)

New York, N. Y.—The Third Avenue Railway has declared a semi-annual interest payment of 1¼ per cent on the $22,536,000 5 per cent adjustment income bonds payable on Oct. 1. The bonds have been on a 2½ per cent annual basis since 1924. After the October payment arrearages will total 35¼ per cent.

✦

Saskatoon, Sask.—Extensive development of the railway system owned by the city is under consideration by the City Council. It is proposed to establish a shorter route to the Sutherland district, to establish railway service to University Heights subdivision over 25th Street bridge and to extend the services on Avenue L. Extension of services along Twelfth Street east to Albert Avenue and on Albert south to Eighth Street are also under consideration.

✦

New York, N. Y.—The Transit Commission engineers testify that it would cost $6,000,000 extra to build the city's proposed Sixth Avenue subway with the present elevated structure of the Manhattan Railway left standing.

✦

Nashville, Tenn. — A petition asking that the Nashville Railway & Light Company be required to furnish the Nashville Interurban Railway with the current necessary for its operation, has been filed in Part II of Chancery Court before Chancellor James B. Newman. The case involves interpretation of the terms of a contract for power entered into between the companies in 1915.

✦

San Francisco, Cal. — Voters of San Francisco will in November pass on the advisability of the continuation of the 5-cent fare for the municipal railway, it appeared after unanimous approval of the proposal by the judiciary committee of the supervisors. However, action upon the proposed amendment to the city charter to fix the rate definitely has been deferred to determine the need for a clause to utilize a tax subsidy in the event of a deficit.

✦

Portland, Me. — General James W. Hanson, chief of highway police of Maine, writing in the *United States Daily*, says that the Maine anti-hitchhiking law has been effective and is a deterrent to the very great nuisance of soliciting transportation from passing motorists. Prior to its becoming effective on July 13, 1929, the law was well advertised through the press to the people of the state. Police records do not show a single case of prosecution for violation of this act since it was passed.

✦

New York, N. Y.—Herman A. Metz, who has been asked by the Transit Commission to resign his post as a director of the Interborough Rapid Transit Company, to permit the substitution of a man "more sympathetic toward the commission's policies," stated that he submitted the request to the I.R.T. board and they told him "unanimously to stick." Mr. Metz also said that "if the city's unification plan is something I cannot conscientiously support as fair dealing, it will be time for me to resign, and I will quit then."

✦

Corning, N. Y.—Five cars formerly in service on the Elmira, Corning & Waverly Traction Company's line, discontinued some time ago, have been transferred into cottages of three rooms each by the operator of a camping ground at Lake Lamoka, where they are now in use.

Maryland Operators Discuss Many of the Latest Developments

Cruising down Chesapeake Bay, the members of the Maryland Utilities Association held an enjoyable meeting on Sept. 11-12. The steamer *City of Atlanta,* chartered by the association, provided facilities for the meetings of the transportation, electric and gas groups which were held Wednesday evening and Thursday morning.

At the evening meeting of the transportation group, the chairman, Adrian Hughes, Jr., superintendent of bus transportation United Railways & Electric Company of Baltimore, introduced J. C. Thirlwall of the General Electric Company, who told of trends in urban transportation. Mr. Thirlwall illustrated his various points by means of talking movies, in particular the development of light-weight railway motors and modern cars.

Friday morning's meeting was devoted to a general discussion of car and bus equipment for city and intercity service, under the leadership of Mr. Hughes. Mr. Thirlwall discussed the action of the magnetic brake. The effect is proportionally more on a "greasy" rail than on a clean, dry rail, he said, as there is no reduction in magnetic pull due to rail condition.

That where high rates of acceleration and braking are used it is necessary to have additional supports for passengers, such as stanchions and grab handles, was the opinion of several speakers, including A. T. Clark and D. J. Locke, of the United Railways & Electric Company, Baltimore.

Improvements in equipment demand an entirely new operating technique, according to Mr. Locke. The men must be specially trained to run the new type of vehicle successfully. Operators must understand that they have a vehicle that can be stopped as quickly as a rubber-tired one.

Mr. Hughes compared the results of modern double-deck gas-electric buses of large capacity with old types they had replaced. The new buses make a faster schedule since the design is better, and rapid automatic acceleration is possible. This change has brought new riders.

Labert St. Clair, director of advertising, American Electric Railway Association, warned against making new cars too good, since then they do not wear out, and it is difficult to make replacements before they are entirely obsolete. He also spoke briefly of the results obtained with the 2-cent fare for short-distance riders in Cleveland between the Public Square and Eighteenth Street. At present four times as many passengers are being carried as formerly with an 8-cent fare. There is no reason, believes Mr. St. Clair, why transportation cannot be sold in bulk like electric or gas service, perhaps on a credit basis. This plan preferably should be handled by means of a house-to-house canvass.

At Jamestown, Va., an hour was spent inspecting the ruins of the first English settlement in America. Another stop was made at Yorktown. There golf, bathing, and a bus trip to see historic points in that town and in Williamsburg were the attractions for the delegates. In the evening dancing and bridge were enjoyed.

*The three index numbers marked with an asterisk are computed by Mr. Richey, as follows: Fares index is average street railway fare in all United States cities with a population of 50,000 or over except New York City, and weighted according to population. Street Railway Materials index is relative average price of materials (including fuel) used in street railway operation and maintenance, weighted according to average use of such materials. Wages index is relative average maximum hourly wage of motormen, conductors and operators on 136 of the largest street and interurban railways operated in the United States, weighted according to the number of such men employed on these roads.

Late T. E. Mitten Large P. R. T. Holder

Although published reports of inventory of the late Thomas E. Mitten's estate filed with register of wills showed holdings of only 10 shares of Philadelphia Rapid Transit stock, Dr. A. A. Mitten declares that his father's investment in Philadelphia Rapid Transit stock actually consisted of 20,000 shares. A more careful inspection of the inventory will show, he pointed out, that this stock is held by holding companies, in which his father owned all of the capital stock. Value of the total estate was $3,527,184 according to the inventory filed by the executors. The largest single investment was $1,902,261 in Mitten Management, Inc.

Purchase by City Discussed

The consensus of opinion of members of the transit conference at Philadelphia, Pa., as expressed at the meeting on Sept. 17, was that a special appraisal of the Philadelphia Rapid Transit Company and the underliers should be made, in line with the movement of the conference to bring about purchase by the city.

In discussing the proposed project, Deputy City Comptroller Wilson pointed out that the most the city could be expected to pay was from $130,000,000 to $150,000,000. He stressed the necessity of quicker action by the conference, stating that the city's borrowing capacity was at the present time insufficient to meet the need of the city for further improvement and municipal projects planned. He contended that purchase of the transportation system would increase the city's borrowing capacity by from $100,000,000 to $130,000,000.

Mitten Management pledged to the conference complete co-operation in making the proposed appraisal of P. R. T. property. Moreover, the conference was assured that earnings of P. R. T. for 1930 would be more than sufficient to meet common and preferred dividend requirements.

Louisville Curtails Its Advertising Activities

James P. Barnes, president of the Louisville Railway, Louisville, Ky., has announced the discontinuance of the publicity department of the company and the position of publicity director, held by Earl D. Hale.

Regret was expressed by Mr. Barnes at the step, made necessary, he said, by the continued loss in passenger revenue which compels the company to curtail every activity not directly relating to operation of the system. Mr. Barnes said:

"It is a matter of grave regret to the management that at the present time we are forced to stop all our advertising activities. Personally, I regard this as a backward step which we are forced to take in view of the exigencies of the situation. Mr. Hale has more than fulfilled our expectations as the publicity director of our company, and I am sorry that present conditions make it necessary for us to discontinue his department."

PERSONAL MENTION

Walter J. Cummings Made a Brill Officer

Railway Executive and Manufacturer With Wide Experience in Both Sides of Local Transportation Industry in New Affiliation With Great Potentialities

WALTER J. CUMMINGS, president of the Cummings Car & Coach Company, Chicago, Ill., was elected a director and vice-president of the J. G. Brill Company, at a meeting of the Brill board on Sept. 9. Mr. Cummings will be in charge of Brill's Western division and will make his headquarters in Chicago.

In a statement issued at that time Samuel M. Curwen, president of the Brill Company, and Mr. Cummings expressed the belief there is a distinct tendency toward an improvement in the future railway business

W. J. Cummings

and that a large quantity of new rolling stock will be purchased within the next few years.

Never has Mr. Cummings been anything less than enthusiastic about the future of local transportation. His ardent belief in that future was perhaps best expressed in an interview published in ELECTRIC RAILWAY JOURNAL for March 27, 1926. He has steadfastly held that the essential nature of the service rendered made the position of the electric railway fundamentally sound. He has, however, been fully cognizant of the possibilities of the bus and of the trolley bus. He has believed that the bus added a new valuable agency for handling a type of service that did not justify railway construction and contended that bus operation by electric railways need not be a losing venture when approached from the proper viewpoint.

As was said of Mr. Cummings in the JOURNAL for Sept. 3, 1927, at the time of his election as president of the Chicago & West Towns Railway, he knows the railway business as a manufacturer and operator, senses its needs and has confidence in its future. His active interest in the industry dates back about 25 years when the successful foundry and forging business that had been built up by the Cummings brothers was expanded through the purchase of the McGuire Manufacturing Company, well-known manufacturers of trucks and sweepers. Mr. Cummings' more recent active connection with the industry has been reflected in the rehabilitation of the Des Moines City Railway under his presidency.

Mr. Cummings was born on June 24, 1879, at Springfield, Ill. His early training was in the banking business. The Chicago & West Towns Railway, over which he assumed executive control in 1927, operates 67 miles of electric railway in the section lying just west and southwest of Chicago. In addition, it owns more than 7 miles of track which are leased to the Chicago Railways. The West Towns company also operates bus lines supplementing its railway service.

Frank T. Post Heads Spokane United Railways

Frank T. Post has been elected president of the Washington Water Power Company and affiliated companies, including the Spokane United Railways, and J. E. E. Royer has been made general manager and R. B. Childs assistant general manager.

Mr. Post succeeds the late D. L. Huntington. He has been general counsel of the Washington Water Company since 1909 and a vice-president since 1926. He is the fourth president of the company since its organization in 1889. Mr. Post has been a resident of Spokane since the spring of 1889, the year of the great fire. He began practicing law at Lowville, N. Y., 43 years ago. He is the senior member of the law firm of Post & Russell.

Mr. Royer is the seventh general manager of the company, succeeding the late Miles W. Birkett. Mr. Royer entered the employ of the company in 1907, his first work being with construction crews in connection with the maintenance of power stations and substations. He was next assigned to the light and power department and in 1919 was made assistant superintendent of that department. On Nov. 1, 1924, he was appointed assistant general manager.

Mr. Childs, the new assistant general manager, has been a commercial engineer with the company since 1923. He came to the Washington Water Power Company from the Intermountain Power Company and was with the Montana Power Company previously. Mr. Childs was a captain in the 363rd infantry regiment of the 91st division during the World War.

Charles J. McMorrow, supervisor of service for the Springfield Street Railway, Springfield, Mass., for the last ten years and for 24 years an employee of the company, has resigned to become sales manager for a real estate company in Springfield.

Advancement from the Ranks in Rochester

Three advancements in the service of the New York State Railways, Rochester lines, have been announced by John F. Uffert, general manager.

John E. Greene, formerly assistant claim agent, becomes chief claim agent under the ancillary receivership of the railways and its subsidiaries, the Coordinated, Interurban and East Avenue bus lines. He has been in the company's employ for twenty years.

Promotion of John J. Sharley from claim agent to superintendent was also announced.

A. P. Griswold becomes assistant claim agent.

H. C. Elliott Promoted by Insull Interurbans

H. C. Elliott, for many years popular at Racine, Wis., as traffic agent for the "Road of Service," has assumed his new duties as general agent of the North Shore Line, Chicago, Aurora & Elgin Railroad and the Chicago, South Shore

H. C. Elliott

& South Bend Railroad, with headquarters in Chicago.

Efficient and courteous performance of duties featured the career of Mr. Elliott since he joined the North Shore Line on June 13, 1924, as information clerk in the traffic department. In September of the same year he was transferred to the transportation department, in a similar capacity. On Nov. 1, 1924, Mr. Elliott was appointed traffic agent at Kenosha. Later he was transferred to Racine, where his geniality and painstaking efforts to serve customers made many new friends for the company, resulting in his new appointment.

H. R. Erickson, traffic agent at Kenosha, has taken over Mr. Elliott's duties at Racine.

Hugh Bradley With Commonwealth & Southern

Hugh Bradley, for some time connected with the law firm of Martin, Thompson, Turner & McWhorter, at Birmingham, Ala., has accepted a position with the secretarial department of the Commonwealth & Southern Corporation, New York.

Mr. Bradley attended the University of Alabama from 1918 to 1922 receiving his A. B. degree in 1922. Following his graduation, he entered the law school and while

Digitized by Google

studying law was an instructor in the department of political science and economics.

Before finishing his law course, Mr. Bradley was awarded a Rhodes Scholarship and took up his residence at Brasenose College at Oxford University in the Fall of 1924. While at Oxford he studied jurisprudence and received his A. B. degree in this subject in 1927.

On returning from Oxford, he was employed by the University of Alabama in extension work and conducted classes in various parts of the state in both history and economics, giving up this work with the university to join the firm of Martin, Thompson, Turner & McWhorter about Sept. 1, 1928, from which he resigned to accept his new situation.

St. Louis Superintendents in New Posts

Four veteran superintendents have been transferred to new stations by the St. Louis Public Service Company. Laurence Kearns has been changed from Kossuth to Park Avenue, George F. Trotter moving into Kossuth, M. A. Hallen has taken up his new duties at South Broadway, while W. P. January is now at Jefferson and Geyer.

Mr. Kearns began his career with the company in 1909 at the Virginia and Walsh sheds. He was made a night clerk, and later assistant foreman. In 1914 he was promoted to chief clerk to the superintedent of transportation. He served one year with the American Expeditionary Forces. Two years after his return from France, he was made relief superintendent, and in 1923 he became superintendent of the Easton station, holding that post six years. In November, 1929, he was transferred to Kossuth station.

Mr. Trotter has been with the company and its predecessors for almost 40 years. He started with the Lindell Railway in 1891 and received his first promotion in 1894.

Mr. Hanlen began as a conductor on the Lee line in 1911. He has held many station office jobs and was made superintendent for the Jefferson and Geyer station in 1925. He was in France with the American forces for eighteen months.

Mr. January also started with the company in 1911. His first work was as a conductor at South Broadway. He was made night clerk a year later and then receiver at the South Broadway station. Later he became night foreman, but in 1925 he was promoted to day foreman at Newstead Station. In 1928 he became superintendent at Park Avenue.

Frank Walsh on Interborough Board

Frank Walsh, attorney, has been nominated as director of the Interborough Rapid Transit Company, New York, by the transit commission. He succeeds William W. Niles, whose three-year term has expired.

Mr. Walsh will represent the public on the Interborough Rapid Transit board. He is understood to favor unification if satisfactory terms can be reached for the city.

The new director has been a member of the American bar, specializing in public utilities, for more than 40 years. He was a member of the commission appointed by Governor Roosevelt to study the Public Service Commission Law and was co-author of the minority report.

In 1912 he was appointed by President Wilson to head a national commission on industrial and economic relations. During the war he was a member of the Labor Conference Board.

Herman A. Metz and A. E. Blackmar are the other "public" directors.

"Clint" Spurr a Bank Director

Announcement has been made of the election of A. C. Spurr, general manager of the Wheeling Traction Company, Wheeling, W. Va., to be a director of the National Exchange Bank of Wheeling.

Election of Mr. Spurr increases the National Exchange board to a membership of eleven. He brings to that body an extensive experience as a business and public utilities executive. Although he has been located in Wheeling only a few years since assuming charge of the Wheeling Traction system, Mr. Spurr has gained a commanding place in both business and civic affairs. He is a past president of the Public Utilities Association of West Virginia, a past president of Fort Henry Chapter Reserve Officers' Association, chairman of the Activities Committee of Oglebay Park and a member of the boards of directors of the Wheeling Y. M. C. A. and the State Fair Association.

H. B. Fleming Made President of Chicago City Railway

Harvey B. Fleming has been elected to succeed the late Leonard A. Busby as president of the Chicago City Railway, the Southern Street Railway and the Calumet & South Chicago Railway, all of which are parts of the Chicago Surface Lines system. Under Mr. Busby, Mr. Fleming had been vice-president of the three companies as well as chief engineer of the Surface Lines. He began his career with the Surface Lines in 1899.

Mr. Fleming was also chosen as a member of the board of operations of the Surface Lines to succeed Mr. Busby. He was likewise made a member of the executive committee of the board of operations.

Harry P. Weber, law partner of Mr. Busby, was elected vice-president and general counsel of the three companies of which Mr. Fleming is president.

Henry C. Page Retires from Worcester Street Railway

HENRY C. PAGE has retired as general manager of the Worcester Consolidated Street Railway, Worcester, Mass., a veteran railroader, battle-tried but not battle-scarred, to take a vacation "for the rest of my life." A genial spirit and a deal of a philosopher, Mr. Page will not fret and rust because he is no longer pinned to a schedule. There are fish to catch, games to play, books to be read, friends to cultivate.

As the *Worcester Telegram* so aptly put it, Mr. Page has seen about all there has been to see in the development of urban and interurban rail transportation. He began in the ranks and brought himself up to leadership. As a conductor he rode the old cars in the days when a plodding pair of horses, with an extra horse at the hills, supplied the motor power. He was on the reception committee which welcomed electricity. He served through the boom time when trolley lines simply could not be chartered, built and operated fast enough, and when President Mellen of the New Haven was acquiring them with the lavish gestures of a Rajah buying Koh-i-noors.

Under the changed economic conditions of the last decade, Mr. Page has been a really courageous fighter. For a good many years he has been getting Worcester's residents down to their jobs in the morning and back at night safely, inexpensively and on time. He knows all about blizzards and traffic snarls and labor relations and all the other things with which a trolley line operator has to perplex himself. He has worked hard and intelligently and he has enjoyed doing it. As the *Worcester Telegram* so generously said, when you come to think it over "Worcester owes something to that kind of a man."

Mr. Page began his railway career more than 45 years ago as a conductor with the Lynn & Boston Street Railway. He was rapidly promoted with this company and finally was placed in complete charge of the schedule arrangement and car dispatching. When the Boston & Northern Street Railway was formed, Mr. Page was retained by it and was promoted from time to time until he became general superintendent in charge of 405 miles of track. In this capacity he was particularly successful in handling the employees, and in his arrangement of the schedules.

In 1903 Mr. Page become general manager of the Berkshire Street Railway, Pittsfield, Mass., and remained with that company until June, 1905, when the property passed into the hands of the New York, New Haven & Hartford Railroad. At the same time the Springfield Street Railway was also taken over by the New Haven, and Mr. Page was appointed general manager of the Springfield Company. In November, 1907, he was elected vice-president of the Springfield Street Railway and continued in this capacity until September, 1909, when he was appointed general manager of the Worcester Consolidated Street Railway and affiliated companies to succeed E. G. Connette. He has served the Worcester Company continuously since that time.

E. J. Bock Supervisor of Stations for Chicago "L"

Edward J. Bock, former trainmaster at the Highwood yards of the North Shore Line, has assumed the duties of general station inspector of the Chicago Rapid Transit Lines. Before joining the "L" lines, Mr. Bock was employed with the North Shore Line for twelve years. He entered the employ of that interurban line in October, 1918, as assistant superintendent of transportation, serving in that capacity, and as superintendent of freight until Jan. 1,

Digitized by Google

1924, when he was appointed supervisor in the transportation department. On Feb. 1, 1927, he was appointed yardmaster and on Feb. 15, 1929, was named trainmaster, being employed in that capacity until shortly before his transfer to the Rapid Transit Lines.

R. C. Forman in New Stone & Webster Post

R. C. Forman, well known for his personnel work with Stone & Webster companies, has been transferred from the Virginia Electric & Power Company, Richmond, Va., to the property of the Western Public Service Company at Scottsbluff, Neb.

Mr. Forman has taught at Louisiana State and Texas Universities, has taught in several high and normal schools in Texas, has been a traveling salesman, and was teaching salesmanship and public speaking when he joined the Stone & Webster organization in Texas some years ago.

R. C. Forman

Devoting his attention to public speaking and personnel improvement work of a general nature, he has, since his affiliation with Stone & Webster, carried on his activities on many of their properties in the Southwest and the Old South. The latest scene of his endeavors has been the various properties of the Virginia Electric & Power Company, with headquarters in Richmond.

Mr. Forman is a good "mixer," and has been very popular with the personnel of every organization with which he has been associated.

He was born in Mississippi and attended Louisiana State University, where he was graduated in 1917 with an A.B. degree. Following this he engaged in post-graduate work at the University of Nashville, the University of Texas, and the University of Chicago. While attending the latter institution he took up special work in public speaking, following this with a course at the Boston School of Expression.

F. T. Whiting Westinghouse Official at Chicago

Fred T. Whiting has been appointed assistant manager of the northwestern district of the Westinghouse company under N. G. Symonds, commercial vice-president. Mr. Whiting was graduated from Iowa State College in the class of 1913, and immediately entered the apprenticeship course of the Westinghouse Machine Company. In 1915, he joined the sales department at East Pittsburgh, but was transferred to Chicago in 1917. He served in the United States Army for two years as a major in the Fifth Engineers Corps, returning to Chicago to assume his former duties. He was manager of the engineering division of his company from June, 1920, to June, 1921, and then became industrial manager, a position he occupied until his appointment as assistant manager of the northwestern district. Mr. Whiting was born and reared in Iowa.

W. Howe Sadler with Kentucky Utilities

W. Howe Sadler, Louisville, Ky., has been named by the Kentucky Utilities Company as manager of its public information, advertising departments, to direct publicity and advertising, and kindred activities, succeeding J. Earle Davis, resigned. Mr. Sadler went to Louisville four years ago from Atlanta. He started his newspaper work with the *Daily Capital*, of Topeka. He attended the University of Arkansas and Kansas University. He holds a lieutenant's commission in the 313th Cavalry, being a member of the Reserve Officers Association. With the Kentucky Utilities Company he will come in contact with railway, bus, power, ice, water, gas and various other units under the control of this large Insull organization.

W. J. (Jerry) Stanton Sells His Cuban-American Holdings

W. J. Stanton, for more than two years vice-president and treasurer of the Cuban-American Manganese Corporation, New York, has disposed of his holdings in that organization, controlling interest of the company having been purchased by the D. M. Goodrich Company.

For a number of years Mr. Stanton was employed by the General Electric Company and the Ohio Brass Company in the engineering and commercial departments and, in this capacity, traveled to all parts of the United States building up, incidentally, an extensive acquaintance among public utility executives and operators.

Mr. Stanton has made no definite arrangements for an immediate future, but it is quite probable that he will again enter the public utilities supply field, with which he has been so long associated.

C. R. Jones Promoted

The Westinghouse Electric & Manufacturing Company announces the appointment of Charles R. Jones as assistant Northeastern transportation manager.

Mr. Jones entered the employ of the Westinghouse Company shortly after he was graduated from the University of Pennsylvania. After completing the company's apprenticeship course, he was assigned to duties in the railway department at East Pittsburgh headquarters, and specialized in electric railroad work. Since 1911, he has represented the Westinghouse Company in the railroad and electric railway fields in the New York district.

George Keller, truck service engineer of the J. G. Brill Company, resigned on Aug. 15 to engage in the garage business in Philadelphia.

R. P. Tarbell in Executive Post With Welding Engineers

Ray P. Tarbell has recently become a member of the firm of Robert E. Kinkead, Inc., consulting welding engineers, Cleveland, Ohio. He was formerly Cleveland district sales manager of the Lincoln Electric Company, manufacturers of "Stable-Arc" welders and "Linc-Weld" motors.

In his new position, Mr. Tarbell will be connected with a firm which has established a national reputation as specialists in a new division of consulting engineering work. Robert E. Kinkead, Inc., serve as welding engineering consultants for large steel companies, steel fabricators and manufacturers of mechanical equipment. They also supervise the establishment of welding departments within industrial firms and direct the methods of welding procedure and control and the redesign of products for arc welded steel construction, a field in which Mr. Tarbell in his

R. P. Tarbell

former capacity has been actively engaged for many years. As vice-president and secretary, Mr. Tarbell will aid Robert E. Kinkead, well known authority on welding procedure and control, in his executive duties as president of the firm which bears his name.

Mr. Tarbell entered the employ of the Lincoln Electric Company in 1918. He was afterward promoted to the sales force and later made district sales manager of the company. He attended Dartmouth College.

Heber LaMonte Acts for Indiana Railroad Only

In the September issue of ELECTRIC RAILWAY JOURNAL, in the article regarding the change in the personnel of Indiana Railroad as successors to Union Traction Company of Indiana, there was a paragraph to the effect that "Heber LaMonte will be superintendent of motive power of the joint properties, reporting to Mr. Bucher."

This paragraph is in error. Mr. LaMonte was superintendent of motive power of the Union Traction Company, and continues as superintendent of motive power for Indiana Railroad. The paragraph just quoted would rather indicate that he had been placed in charge of the motive power departments of the different companies of the system. This is incorrect.

OBITUARY

Frank R. Ford

Frank R. Ford, a founder and member of the consulting engineering firm of Ford, Bacon & Davis, Inc., died on Sept. 17, following an operation, at the age of 59 years. Active for 39 years in the public utility and industrial engineering field, and intimately connected with electric railway problems throughout this period, the passing of Mr. Ford is a grave loss to the entire industry. Since the work of the company of which he was the head included consultation, design, valuation, reports and management of utilities and industrial enterprises which present engineering problems, Mr. Ford was a vital force in the development of American industry. Concentrating in the earlier years on the firm's activities on the planning and construction of electric railways, Mr. Ford assisted in assembling one of the most valuable collections of electric railway statistics in this country.

Frank R. Ford

Among the outstanding achievements of Mr. Ford and his associates were the reorganization of the Metropolitan Street Railway of New York City, the electrification and unification of railway lines in New Orleans, management of the Philadelphia Company at Pittsburgh for several years, the unification of the Chicago railways in 1905, the rebuilding of the San Francisco railway system after the earthquake, and the reorganization of the Philadelphia Rapid Transit Company in 1911. Necessarily the history of his firm is largely the history of Mr. Ford.

Following the graduation of Mr. Ford from the University of Pennsylvania with the degree of B.S. in 1890, and the advance degree of M.E. in 1891, he served with several electric manufacturing concerns, among them the Short Electric Railway Company, Cleveland. In 1894 Mr. Ford and George W. Bacon formed the consulting engineering firm now known as Ford, Bacon & Davis, Inc. Mr. Davis was admitted to the partnership in 1895. Among the earliest undertakings of the company was the electrification of the railways of New Orleans, including the Orleans Railroad and the Canal & Claiborne Railroad, and the re-equipment of the New Orleans & Carrollton Railroad, Light & Power Company. Following the completion of this work the firm assisted in the unification of the individual systems. Subsequent modernization and reorganization of several other southern properties led to the formation of the American Cities Company, which controlled and managed the systems until 1917.

Another early achievement of the company under Mr. Ford was the rebuilding in 1900, following the purchase in 1898, of the rail line, extending from Edgewater, N. J., opposite New York City, to Leonia. In rebuilding this system and extending it to Hackensack many difficult engineering problems had to be solved.

Two more major activities followed shortly—the electrification and rebuilding of the cable railways of Kansas City in 1901 and the rehabilitation in the same year of the Short Line from Ardmore, Pa., to Llanerch, now known as the Philadelphia & West Chester Traction Company.

In the following year the firm was engaged to develop a unified system of all the street railways in Chicago by the city. It made a detailed study and submitted a comprehensive report which was accepted. The firm was then retained to assist in carrying through the program and putting the system into effect.

A few months before the earthquake which occurred in San Francisco in April, 1906, Ford, Bacon & Davis purchased with others the United Railways, San Francisco, the predecessor of the present Market Street Railway. Following the fire Mr. Ford participated actively in the work of rebuilding the property. The railway was managed by the company until 1926, when it was sold to Byllesby.

In 1910 the firm investigated the property and operations of the Philadelphia Rapid Transit Company for the State Utilities Commission. The recommendations prescribed standards by which the adequacy and efficiency of a railway's operations may be determined. The company was also employed by the city of Philadelphia in 1912 to investigate and report upon a proposed system of subways and elevated railroads. As a result, a report was prepared in collaboration with Transit Commissioner A. Merritt Taylor, which, it is said, was the most comprehensive study of high-speed transportation ever made. The firm was subsequently engaged for three years as consulting engineers on the construction design of the system. For the past two years the company has been making a valuation of Philadelphia Rapid Transit Company holdings.

One of the largest acquisitions of the firm, made in 1912, was that of the Philadelphia Company, owning the rail, light and gas systems in Pittsburgh. These properties were completely rehabilitated shortly after the purchase. The system was sold to Byllesby & Company later. The Lackawanna & Wyoming Valley Railroad, built in 1904 by the Westinghouse Company and other interests for testing equipment, was purchased by Ford, Bacon & Davis in 1913.

Active participation in the modernization or rebuilding of large electric railway city properties has been engaged in by the firm in Washington, Baltimore, New York, Brooklyn, St. Louis, Cleveland, Toledo, Providence, Richmond, Nashville, Duluth, Sioux City, Birmingham, Montgomery, Atlanta, Houston, Little Rock, Kansas City, Mobile, Knoxville and Memphis. Work also has been done in many smaller cities and for several interurban electric railways.

During the war the company prepared studies and maps in collaboration with the American Electric Railway Association, of the electric railway facilities along and adjacent to the Atlantic Coast, for the use of the War Department.

Mr. Ford had been an active member of the American Electric Railway Association since the formation of his company and he contributed much of his time to its advancement. In 1896 and 1897 he represented the association at the National Conference of Standard Electrical Rules, which formulated the original National Electrical Code. He was a member of the association's committee on federal relations for many years, and also served as chairman of the committee on rates and fares, a body which submitted a noteworthy report in 1911.

In July, 1917, Mr. Ford was appointed by Governor Edge of New Jersey as a member of the New York and New Jersey Port and Harbor Development Commission, a body which made a comprehensive study and plan of the port of New York. He was appointed a member of the Port of New York Authority in 1921.

Mr. Ford also was a frequent contributor to technical magazines and wrote many noteworthy articles.

Leonard A. Busby

Leonard A. Busby, president of the Chicago City Railway and one of the country's outstanding figures in electric transportation, died on Sept. 9. He had undergone an operation the previous day for a gland ailment from which he had suffered for three years. He was 61 years old. The malady from which he suffered is believed to have been aggravated by his unceasing efforts in connection with the work incident to the unification plan and the drafting and passage of the co-ordination ordinance recently approved at the polls.

Leonard A. Busby

"If ever a man was a martyr, Mr. Busby was," said Melvin A. Traylor, president of the First National Bank, of Chicago. "He should have looked after his physical well-being a year ago, but didn't take time off to do it because of the muddled state of the traction question."

Mr. Busby's death followed by two weeks the death of Frank O. Wetmore, co-chairman of the First National Bank. Mr. Wetmore was a member of a committee of bankers who are lending their aid in

Digitized by Google

the solution of the traction problem in Chicago, and in this work he was closely associated with Mr. Busby. Moreover, the two men were close personal friends.

Mr. Busby was born in Jewett, Harrison County, Ohio. He was graduated in 1894 from Ohio Wesleyan University. He later received his law degree from Northwestern University and, subsequently, for many years was engaged in the practice of law in Chicago.

In 1908 he became counsel for the Calumet & South Chicago Railway. That marked his entrance into the railway field in Chicago. Two years later he became counsel for the Chicago City Railway. In 1911 he was elected president of the Chicago City Railway, the Calumet & South Chicago Railway, and the Southern Street Railway. Following his election to these positions he gave up his law practice.

Soon after taking over his new executive duties, Mr. Busby led negotiations which resulted in affiliation of the Chicago City Railway and the Chicago Railways as the Chicago Surface Lines. He was president of this company from 1914 to 1920. He retained, in addition, his position of president of the three south side surface lines.

Mr. Busby was a member of the finance committee of the National Enameling & Stamping Company; a member of the governing committee of the Chicago City & Connecting Collateral Trust; and a director of the Chicago & Alton Railroad, National Bank of the Republic, of Chicago, and Wilson & Company, packers.

✦

F. R. Fisher

Frank R. Fisher, chief engineer of the Department of City Transit at Philadelphia, Pa., widely known as an expert on subway construction, died suddenly on Aug. 15 at the home of his brother, Frederick S. Fisher, in Lansdowne. Death was attributed to heart disease. He was 58 years old.

Soon after his graduation from Lehigh University in 1891 Mr. Fisher was appointed to the city's service in the bureau of surveys. During the Market Street subway-elevated construction he was resident engineer for the Philadelphia Rapid Transit Company. He was named chief engineer of the Transit Department in 1924.

✦

J. L. Esson

John Leonard Esson, well-known engineer and vice-president of Ford, Bacon & Davis, Inc., New York, died suddenly on Sept. 21 at the age of 52.

Mr. Esson was a native of Glasgow, Scotland. His parents settled in Chicago when Mr. Esson was a boy. There he was educated in the Chicago Manual Training School, since absorbed by the University of Chicago. His first work was in the accounting field, but 23 years ago he turned to engineering.

In his new field he became expert as a business consultant and economist, his advice being sought in many important projects in this and other countries.

✦

John H. Sheridan

John H. Sheridan, former superintendent of employment of the Los Angeles Railway, Los Angeles, Cal., is dead. Mr. Sheridan entered the employ of the Los Angeles Railway on Jan. 1, 1915, as special representative. In August, 1917, he was appointed an investigator in the claim department, which position he held up to the time of his transfer as investigator in the employment office. In this capacity he served until September, 1928, when he was appointed superintendent of employment.

As a boy, Mr. Sheridan took up telegraphy, later moving to Boston to work for the Boston & Maine Railroad. Like many other men, he heard the call of the West, and he entered the employ of the Southern Pacific Railroad. With this organization he worked his way up to chief dispatcher of the San Joaquin Division. He returned East for a short time only to return to the West as train dispatcher for the Santa Fé Railroad.

✦

Frederick Guilfoyl, superintendent of the American Brake Company's St. Louis, Mo., plant, died on Sept. 17 after an illness of eight weeks. Mr. Guilfoyl went to St. Louis from Pittsburgh, Pa., 25 years ago to become superintendent for the brake company. Prior to that he had been associated with the Westinghouse companies in the Pittsburgh district for about ten years.

Thomas F. Griffith, for the past ten years superintendent of the Lexington division of the Middlesex & Boston Street Railway, Boston, Mass., died on Sept. 9. He was born in County Galway, Ireland, on Dec. 13, 1872, but had lived in this country since a young man. He was one of the oldest employees in point of years of service of the Middlesex & Boston Street Railway, formerly the old Lexington & Boston Street Railway.

✦

Hermon Bongard, long a district and then a division superintendent of surface lines in Brooklyn, which he served for 40 years, died on Sept. 6, after a long illness. He was 60 years old.

✦

William P. Stanton, an investigator for the St. Louis Public Service Company, St. Louis, Mo., died on Sept. 14 following several weeks' illness. In his work for the company's claim department he usually answered the call docket for damage suits filed against the company in St. Louis Circuit Court.

INDUSTRY MARKET AND TRADE NEWS

Gain Over 1929 Reported by J. G. Brill

Distinct improvements over 1929 have been indicated in the business of J. G. Brill Company for this year. Sales thus far in 1930 have run consistently ahead of the same period for last year. The full year will undoubtedly show a satisfactory increase over 1929, when the company reported total sales of $6,457,630.

No new large orders have been received recently, still bookings at the present time are 10 per cent to 15 per cent higher than at this time last year. To the Gulf, Mobile & Northern Railway was shipped, in the early part of September, an unusually long and powerful motor car train, propelled by a single gas-electric power plant. Shipment was made up of a model 860 motor car and four trailers, together with an additional motor car.

Although further pick-up in business is expected to be slow, the outlook is considered favorable.

Sales of Ohio Brass Hold Up Well

Showing a continued strength in sales, the Ohio Brass Company has been able to maintain the annual extra dividend of $1 on the common stock, started last year. This reflects the small percentage of decrease in earnings the company has experienced for the year.

July and August showed some decline in the industry. Satisfactory increase for the month of September is reported by the Ohio Brass, and prospects for October and November appear even better. The expansion programs which the public utility companies are putting into action are expected to reflect favorably in the sales of Ohio Brass manufactured products.

Although the earnings so far this year have fallen from the level of 1929, when the company earned $7.78 per common share, compared with $5.24 in the previous year, it seems probable that net profit for the full 1930 year will be above the 1928 figure. The volume of export business for the year has had a substantial increase. Further increase is probable as a result of a prospective contract with the Egyptian Government and negotiations carried out with India and the Soviet Government regarding other contracts.

More Buses Are Delivered by Manufacturers

Deliveries of buses to electric railways continue to maintain a steady and normal pace at this time of the year. No unusually large order has appeared; many have been for one or two units. An interesting delivery was that of seven trolley buses by the Twin Coach Corporation to the Chicago Surface Lines to add to its present fleet of 55. Twin Coach also made deliveries of two large-capacity urban buses to the United Electric Railways, Providence; three of this type to Aronimink Transportation Company, Upper Darby, Pa.; and of the small-capacity type, the Eastern Texas Electric Company received three, and the Cincinnati Street Railway, two.

From the General Motors Truck Corporation, the Connecticut Company, New Haven, received eight Type Z, 38-passenger city service coaches; Potomac Edison Company, Cumberland, Md., seven Type U, 21-passenger city service coaches; Illinois Power & Light Company, Champaign, three Type Z, 29-passenger city service coaches; Mississippi Valley Electric Company, Iowa City, three Type U, 21-passenger city service coaches; Eastern Texas Electric Company, Beaumont, two Type U, 25-passenger city service coaches; and the North Carolina Public Service, Greensborough, one Type W, 23-passenger city service coach.

Boston Elevated Railway accepted deliv-

Digitized by Google

ery of ten A. C. F. 40-passenger, all-steel metropolitan coaches. Triple Cities Traction Company, Binghamton, received from the same manufacturers two 33-passenger street car coaches.

White Company made deliveries of twelve buses divided as follows: five Model 65A, to Louisiana Power & Light Company, Algiers, La.; one Model 65 and one Model 65A to Denver Tramway Corporation, Denver; two Model 54, to West Penn Electric Company, Pittsburgh; two Model 61, to Susquehanna Transit Company; one Model 54A, to the Boston, Worcester & New York Railway; one Model 65A, to the Burlington Rapid Transit Company, Burlington, Vt.; and one Model 65, to the West Short Transit Company, Annapolis, Md.

Deliveries by the Mack-International Motor Truck Corporation consisted of four Model BC equipped with 29-passenger city type bodies to the Louisville Railway, two Model BC to the Denver Tramway, and one Model BG to the Fishkill Electric Railway, Beacon, New York.

Copper Lowest in 30 Years at 10¾ Cents per Pound

Domestic price of copper was reduced during the past month by leading producers from 11 to 10¾ cents per pound, while at least one custom smelter, that had been quoting 10¾ cents, reduced its price to 10¼ cents. These new prices are the lowest in 30 years, and compare with 18 cents in effect from April, 1929 to April, 1930, when the decline began. Despite the slash, little metal was disposed of. It was reported that consumers who had placed large orders in June and July have deferred delivery.

General expectancy among speculators of a further drop has been a factor in holding back orders from consumers. Statistics of the August report disclose an increase of more than 25,000 tons in stocks of refined copper for that month. This is regarded in some quarters as presaging a further lowering in price in the effort to get sales; and it is also pointed out that large producers have known that stocks have been increasing and that, if a further cut was in mind, it would have come before this time.

American Brass Company, controlled by the Anaconda Copper Mining Company, has announced recently a ¼-cent reduction in all brass and copper products, including scrap and seamless tubes. The cut in prices was first announced by the Anaconda Wire & Cable Company, and was later met by the Chase Metal Company and Revere Copper & Brass Company.

G. E. Questions for Welding Inspectors

As an aid in the instruction of inspectors in the elementary and fundamental features of arc-welding as applied to ordinary steel building construction, a group of 35 questions with answers have been prepared by Frank P. McKibben, consulting engineer of the General Electric Company.

The co-operation of welding engineers, contractors and building commissioners was enlisted in this undertaking. A great many of the questions are of an elementary nature to enable men who have not had much experience with welding to ground themselves in the fundamental principles.

Orders Placed for Supervisory Control Equipment

Steadily increasing trend to supervisory control for centralized remote control of electrical power apparatus is reflected by two large orders recently received by the Westinghouse Electric & Manufacturing Company for Visicode type supervisory control equipment. These orders cover a total of 25 Visicode equipments, five having been purchased by the Long Island Railroad and twenty by the Reading Company. In addition, these orders include the switchboards for the main stations involved.

The Reading Company order covers equipment for the initial railway electrification of their Philadelphia suburban area. Seven power substations and fourteen intermediate stations in this area, which will supply current to the electrified zone of the railroad, will be entirely unattended and will be operated from a central point located in the load dispatcher's office at Wayne Junction by means of the Visicode type of supervisory control. When completed, this will be one of the largest and most extensive supervisory control systems ever installed.

Supervisory control for five substations is covered by the order of the Long Island Railroad. Four of these stations will contain mercury arc rectifiers which will be controlled by means of automatic switching equipment included on this same order. This equipment will, in turn, be remotely operated by the Visicode supervisory control. The other station will contain track breakers which will also be remotely controlled by Visicode supervisory control.

Ten New Locomotives Ordered by the New Haven

Ten 3,500-hp. electric locomotives for service on the New York, New Haven & Hartford Railroad are under construction at the Erie, Pa., works of the General Electric Company. The units, which will operate with either alternating or direct current, will handle main-line passenger trains between New Haven and New York City, including operation over the 600-volt, third-rail section of the New York Central Railroad into Grand Central Terminal or over the Hell Gate route to Pennsylvania Station.

The locomotives will weigh, complete, approximately 200 tons, with 135 tons on the driving axles. Each unit will have a capacity of fifteen 80-ton cars on level tangent track at 65 m.p.h. on alternating current, and at 58 m.p.h. on direct current, with maximum speed of 70 m.p.h.

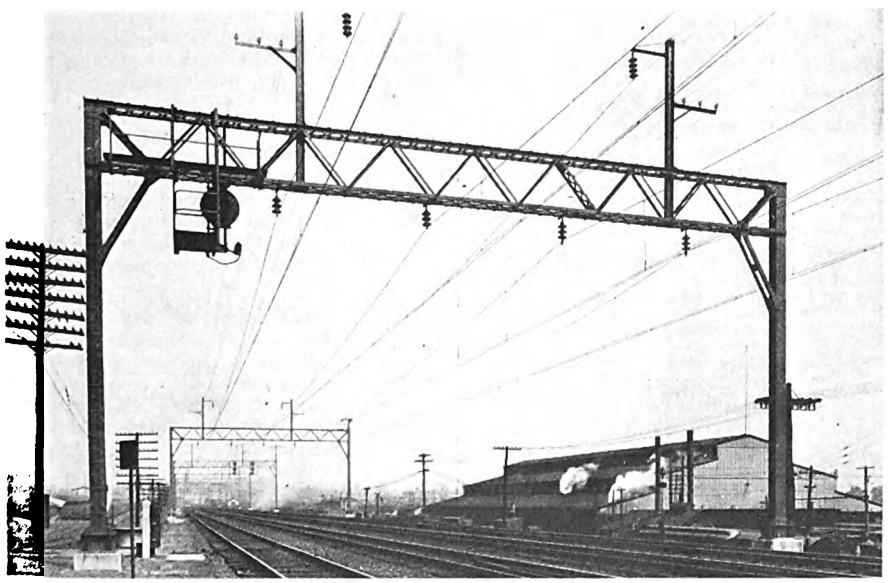
Designated as the 2-CC-2 type, they are equipped with six spring quill mounted, twin-armature, single-phase, commutator type motors designed for operation at 210 volts per armature. Each motor will have a one hour rating of about 575 hp. The two three-axle trucks are connected by an articulated joint with extensions at the outer ends supported on two-axle guiding trucks. The cab is of the box type with an apparatus compartment in the center and an operating compartment at each end. An air blast transformer is used, having reduced capacity taps on the low voltage winding for the protection of compressors and blowers. Both two-stage air compressors have a piston displacement of 100 cu.ft. per minute when operating at a pressure of 135 lb. per sq.in.

The principal dimensions (approximate) are:

Length inside knuckles	77 ft. 0 in.
Length of cab	60 ft. 0 in.
Total wheelbase	66 ft. 0 in.
Rigid wheelbase	14 ft. 0 in.

The cost of the locomotives will be $2,000,000. It is expected that they will be delivered to the railroad before the end of August, 1931.

First Section of Reading Overhead Completed



Work on the electrification of the Reading Railroad in Philadelphia and vicinity is proceeding according to schedule. This illustration shows the first completed section of the catenary and overhead construction, which extends northward from the Market Street terminal

Quigley Company offers for distribution a booklet describing the uses of Annite, a colloidal cleaning compound. This booklet may be obtained by addressing the company at 56 West 45th St., New York, N. Y.

Chrysler Announces Fargo Coaches

Chrysler Motors Corporation, of Detroit, announces the organization of a new division, to be known as Fargo Motor Corporation, which will engage in the manufacture of a line of motor coaches consisting of two series.

The Model 80 series will comprise a conventional 21-passenger coach of the street car type and a 16-passenger parlor coach. The Model 90 series will include a 21-passenger circulating load street car type coach, having a standing capacity of approximately 30 additional passengers; also a 21-25-passenger parlor type coach. The 90 series are said to include a number of original features. The product will be sold by the Fargo Motor Corporation direct to operators.

Lamme Award to Morris Stone

Second award of the Benjamin Garver Lamme Scholarship has been granted to Morris Stone, mechanical engineer of the Westinghouse Electric and Manufacturing Company. The scholarship provides one year's advanced study at any college or university in America or abroad.

This scholarship has been established in perpetuity by the Westinghouse Electric & Manufacturing Company in honor of the late B. G. Lamme, who was chief engineer of the company. Any engineer who has been in the employ of the company one year or more, and evidences unusual promise for future development, is eligible for the award.

Morris Stone was graduated from the Engineering School of Harvard in 1923, establishing scholastic records. Besides receiving the highest academic rating, Mr. Stone was also elected to the honorary engineering fraternity.

In 1925 he received his master's degree from Harvard, and in the same year joined Westinghouse. After working for three years in the research laboratory on general electricity and vibration problems, he was transferred to the power engineering department.

Mr. Stone is the author of several original treatises, specializing in problems dealing with the mechanical aspects of electrical engineering. One article in particular, "The General Torsion Problem," has secured considerable recognition in the engineering world. This paper was presented to the Third International Congress of Engineers held in Sweden in the summer of 1930. Mr. Stone has selected the Universities of Berlin and Charlottenburg at which to continue his studies.

TRADE NOTES

Robert W. Hunt Company, Engineers, announces the retirement of its president, John J. Cone, who has been a member of the company since its organization in 1888. C. B. Nolte, vice-president and general manager, has been elected president and general manager, with headquarters at the general office, Chicago. J. C. Ogden, a director and eastern manager of the company, has been elected vice-president, with headquarters at New York City.

✦

Leeds, Tozzer & Co., Inc., 75 West Street, New York, N. Y., have prepared a 16-mm. moving picture of their automatic car washing machine, with titles in English and Spanish. The film is available, upon request, for display before associations, conventions and sectional meetings.

✦

Ohio Brass Company announces the removal of its Dallas office from the former location in the Insurance Building to 1010 Allen Building, corner of Commerce and Ervay Streets.

✦

Union Metal Manufacturing Company, Canton, Ohio, announces the removal of its Eastern office from Philadelphia to 110 East 42nd Street, New York City. E. B. Comfort, eastern district sales manager, will be located in the same suite with W. A. Daunt, New York sales manager for the company.

✦

Leavitt Machine Company, Orange, Mass., has appointed Charles C. Phelps, manufacturers' agent, 11 Park Place, New York, as its sales agent for metropolitan New York and northern New Jersey to handle the Dexter valve reseating machine for globe, gate and pump valves.

✦

Lincoln Electric Company, Cleveland, Ohio, manufacturer of "Stable-Arc" welders, and "Linc-Weld" motors, announces the opening of new offices in Saginaw, Mich., Fort Wayne, Ind., and Oil City, Pa. The Saginaw office is located at 338 Barnard Street, and is in charge of J. E. Luter. The Ft. Wayne office is in charge of D. H. Carver, and is located at 225 E. Columbia Street; E. D. Anderson is in charge of the new office in Oil City, Pa.

Advertising Literature

Westinghouse Electric & Manufacturing Company offers a 60-page special publication on oil electric locomotives and rail cars. A general analysis of the characteristics and field of application of the oil electric locomotive in comparison with other motive power plants is interestingly presented. Devoted to the selection of equipment is a section giving some short-cut methods to determine the approximate application with the aid of characteristic curves.

✦

General Electric Company has published a treatment on mercury-arc rectifiers for railway use, which is designated as publication GEA-1151A. Characteristics of the mercury arc, rectifier auxiliaries and the cooling system, operating features and construction of rectifiers are covered in this publication.

✦

Sangamo Electric Company, Springfield, Ill., has published in pamphlet form a series of articles devoted to increasing the effectiveness of a load-building program. The articles are illustrated with graphs and charts describing the performance of the Sangamo meters.

✦

Fabrikoid Division of the du Pont Company has issued a booklet dealing with the style, design, color and texture of lacquered fabrics which may be used as substitutes for leather. Many illustrations are given to show how this fabric enters into the decoration scheme of many fields.

✦

General Electric Company has issued a booklet describing briefly copper brazing processes and the copper brazing furnaces which it manufactures. A recently developed process of hydrogen-copper brazing is discussed at some length with a view of presenting some of its advantageous applications.

Electric Railway Material Prices—October 1, 1930

Metals—New York

Copper, electrolytic, delivered, cents per lb.	10.275
Lead, cents per lb.	5.50
Nickel, cents per lb., ingot	35.00
Zinc, cents per lb.	4.25
Tin, Straits, cents per lb.	29.85
Aluminum, 98 to 99 per cent, cents per lb.	23.30
Babbitt metal, warehouse, cents per lb.:	
Commercial grade	37.00
General service	31.00

Bituminous Coal

Smokeless mine run, f.o.b. vessel, Hampton Roads, gross tons	$4.15
Somerset mine run, f.o.b. mines, net ton	1.75
Pittsburgh mine run, Pittsburgh, net ton	1.40
Franklin, Ill., screenings, f.o.b. mines	1.50
Central, Ill., screenings, f.o.b. mines	1.05
Kansas screenings, Kansas City	1.50

Track Materials—Pittsburgh

Standard steel rails, gross ton	$43.00
Railroad spikes, drive ⅝ in. and larger, cents per lb.	2.80
Tie plates (flat type), cents per lb.	2.075
Angles bars, cents per lb.	2.75
Rail bolts and nuts, cents per lb.	3.90
Steel bars, cents per lb.	1.63
Ties, white oak, Chicago, 6 in. x 8 in. x 8 ft.	$1.35

Hardware—Pittsburgh

Wire nails, base per keg	$2.10
Sheet iron (24 gage), cents per lb.	2.40
Sheet iron, galvanized (24 gage), cents per lb.	3.05
Galvanized barbed wire, cents per lb.	2.75
Galvanized wire, ordinary, cents per lb.	2.70

Waste—New York

Waste, wool, cents per lb.	12.00 to 15.00
Waste, cotton (100 lb. bale), cents per lb.:	
White	9.00 to 13.00
Colored	5.00 to 7.00

Paints, Putty and Glass—New York

Linseed oil (5 bbl. lots), cents per lb.	10.8
White lead in oil (100 lb. keg), cents per lb.	13.75
Turpentine (bbl. lots), per gal.	0.485
Putty, 100 lb. tins, cents per lb.	5.50

Wire—New York

Copper wire, cents per lb.	10.75
Rubber-covered wire, No. 14, per 1,000 ft.	$4.62
Weatherproof wire base, cents per lb.	13.375

Paving Materials

Paving stone, granite, 5 in., f.o.b.: New York—Grade 1, per thousand	$150.00
Wood block paving 3½, 16 lb. treatment, N. Y., per sq.yd., f.o.b.	2.50
Paving brick 3½x8½x4, N. Y., per 1,000 in carload lots, f.o.b.	50.00
Paving brick 3x8½x4, N. Y., per 1,000 in carload lots, f.o.b.	45.00
Crushed stone, ¾-in., carload lots, N. Y., per cu.yd., delivered	3.40
Cement, Chicago, in carload lots, without bags, f.o.b.	1.95
Gravel, ¾-in., cu.yd., delivered New York	3.40
Sand, cu.yd., delivered New York	2.15

Old Metals—New York and Chicago

Heavy copper, cents per lb.	8.50
Light copper, cents per lb.	7.75
Heavy yellow brass, cents per lb.	5.50
Zinc, old scrap, cents per lb.	2.25
Lead, cents per lb. (heavy)	4.25
Steel car axles, Chicago, net ton	$15.25
Cast iron car wheels, Chicago, gross ton	13.75
Rails (short), Chicago, gross ton	14.25
Rails (relaying), Chicago, gross ton (65 lb. and heavier)	28.50
Machine turnings, Chicago, gross ton	6.25

Urban Transportation Facilities Keep Pace with Population Increase

EXPANSION of organized public transportation facilities in American cities has continued steadily during the past decade, despite the enormous increase in the use of private automobiles. According to the recently completed United States census of 1930, nearly half of the inhabitants of this country live in 189 cities of more than 50,000 population and in the suburban territory immediately adjacent thereto. Today the combined rail, bus and trolley bus facilities available in these communities are approximately 20 per cent greater than those available a decade ago, while the increase in population has been about 24 per cent. From this it is evident that transportation service has kept pace with the growth of population.

In all but one of these cities of more than 50,000 population the electric railway is the backbone of the local transportation system. Even in the single city where rail service has been suspended, there is lively agitation for its restoration. To serve this immense urban territory the electric railways operate approximately 60,000 passenger cars on slightly more than 23,000 miles of track. This equipment represents 80 per cent of all the electric railway passenger cars in the country, while the track is about 60 per cent of the total electrified mileage, not counting electrified steam railroads. During the past ten years the change in total track mileage has been less than 1 per cent, abandonments in some localities having been almost exactly balanced by extensions in others. Similarly, there has been no substantial change in the number of passenger cars operated on these properties, old rolling stock having been retired to offset the new cars acquired.

TO SUPPLEMENT their rail service the electric railways operate approximately 9,000 motor buses over some 7,000 miles of route in 167 of these cities. This is slightly more than 75 per cent of the total number of buses operated by electric railways in the United States, but the route mileage is only 30 per cent of the total. There is also a small amount of urban bus operation independent of the railways, but this is not an important factor in the transportation situation except in a few cities. Practically all of the present bus route mileage has been added since 1920, there having been less than 100 miles of bus route operated by these electric railways at that date with only a few vehicles.

Recent extensions of trolley bus operation bring the present total length of route to approximately 60 miles and the number of vehicles to about 200. All of the existing trolley bus operations have been undertaken during the past decade, a few earlier installations having been abandoned prior to 1920. While the present extent of this type of operation is comparatively small, there are many indications that the next ten years will see a substantial expansion.

In about a dozen cities the electric railways operate taxicabs as well as rail and bus service. According to the latest available figures approximately 2,500 taxicabs are operated under electric railway auspices out of a total of some 65,000 in this group of 189 cities. While the desirability of co-ordinating the taxicab with other forms of public transportation has long been evident, the lack of adequate regulation has tended to deter the established transportation companies from entering this field. Recently there has been a growing tendency to classify taxicab service as a public utility. When this is done it is likely that the electric railways will expand their activities in this field.

PUBLIC transportation facilities in the smaller cities ranging from 10,000 to 50,000 in population have developed more slowly than in the large cities. The census of 1930 shows 789 cities in this smaller group. Of this number 531 have electric railway service. Among those which do not have rail service a considerable number have bus service. In many instances this is furnished by the same company which formerly operated street cars, while in others the bus operation is under independent auspices. Only about 60 cities have no organized transportation facilities of any kind.

Every reason exists to expect that public transportation facilities in cities of more than 50,000 population will continue to expand during the next ten years. A substantial expansion occurred between 1920 and 1930 despite an increase of nearly 200 per cent in the number of private automobiles. The rate of increase in private transportation facilities, however, is dropping. The fact that the ratio of automobiles to population in the large cities is only about half that in the small cities indicates that congestion is tending to discourage the use of individual vehicles. This is borne out by a recent count in one large city, which showed fewer automobiles entering the business district than were reported five years ago. On the other hand, people have a steadily increasing tendency to go from place to place. This can have only one result: a steadily growing demand for public transportation facilities.

Solving the Problem for Small-City Systems

IN SMALL cities the problem of making the public transportation service self-supporting continues to present serious difficulties. Nowhere has any simple and easy solution been found. But progress has been made in some places as a result of thorough analysis of conditions and carefully organized effort to increase riding.

Many factors affect the success of a small-city transportation property. The business and industrial situation, the provisions of the franchise, the financial structure of the company, the condition of the physical plant and equipment, the morale of the operating organization—these and numerous other things have an important influence.

Thorough understanding of local conditions is essential. This should include the opinions of the company's patrons as well as the opinions of those who do not use the service. Competition from other agencies, location of business centers, changing trends in population, industrial activity, and many other similar factors, must be taken into account.

Among the problems most deserving of study is that of financial structure. Lack of flexibility is frequently a deterrent to progress. In some instances it may be found that securities have outlived the property they represent, or the earnings are too low to justify new capital with a proper return on the old. Drastic readjustment in the financial structure may be necessary to place the system on a sound basis—to assure a fair return on the investment and to enable the attraction of new capital for improvement programs.

Analysis of operating costs will sometimes point the way to substantial savings. This will show whether headways are suited to the traffic demands, whether speed is at a maximum, and whether economies may be instituted without harmful results. Although expenses must of necessity be adjusted to the level of earnings, there is often grave danger in going too far in effecting economies. High-grade service is absolutely necessary if a railway is to build up its business, and this should not be hampered by unwise economy measures.

Another factor which demands careful consideration is the equipment. Three distinct types are now available —the street car, the trolley bus and the gasoline bus. Each has a different field of usefulness. If an analysis shows one type of vehicle to be better suited for meeting the requirements than another, the management should not hesitate to make the change as quickly as it is possible to do so. In this respect, the operator must take the attitude that he is primarily a transportation man and not simply a street car or bus operator.

Having analyzed the operating conditions in detail, the small-city manager might well concentrate on a definite program of merchandising. Fundamentally, merchandising involves three distinct steps—the production of a salable product, pricing this product so that it will appeal to the purchaser, and the actual selling. In the matter of pricing, comparatively little experimentation has been done. The old-fashioned flat fare still prevails in most cities. Undoubtedly a real opportunity exists to make improvements in this respect.

Actual selling of the service requires the whole-hearted and active co-operation of every member of the railway organization. Although the men on the cars have the best opportunity to promote business, all of the others play important parts. Market analyses; soliciting patronage by house to house campaigns; offering special inducements; notifying the public of service, equipment or fare changes; bettering the public relations at every opportunity and supplementing these efforts with skillful, well-planned advertising, are among the many steps that can be taken in an intensive merchandising campaign.

Prompt action is needed in attacking the small-city problem. Delays only add to the difficulties. Haphazard efforts in attempting to find a solution only lead to further complications. Obviously, the first step is a thorough analysis of the situation on each individual property.

Taxicabs as a Public Utility

OF PRIME importance to all local transportation interests are the recommendations presented in the comprehensive report of the Mayor's commission on taxicabs for the city of New York. Briefly, it is proposed that the business be established as a public utility under a bureau of taxicab control, that certificates of convenience and necessity be required and that taxicabs be operated under a single franchise in co-ordination with other transit agencies. Directly affecting about 20,000 cabs, a substantial proportion of the total number in the United States, these recommendations are likely to have a far-reaching influence on the entire industry.

It has long been contended that the unhealthy condition of the taxicab industry could best be cured by placing it in the category of a common carrier. This has already been done on a state-wide basis in Arizona, Connecticut, Maryland, Oklahoma, Pennsylvania and Rhode Island and in about a dozen cities in other states. That it should be done in the city of New York is the opinion of the commission.

Granting certificates of convenience and necessity will have two important results. It will limit the number of cabs in use, thereby permitting them to operate more efficiently and more profitably, and it will also raise the standards of service by imposing strict requirements on the drivers. Experience in the states and cities where this arrangement is in effect has demonstrated its advantages.

Regulation of taxicabs as a public utility and the issuance of certificates are intended, according to the New York report, to serve as stepping stones to the ultimate granting of a single franchise for the entire city. This proposal has naturally evoked protest from individual operators, small-fleet owners and interests dependent on these groups. Whether or not it would be advisable to have a complete monopoly of taxicabs in New York City is a matter of opinion. It has been found in several other cities, however, that taxicabs can be operated to the best advantage by large companies. With the pressing need for co-ordination of all transit facilities, the monopoly plan for taxicabs probably will grow in favor.

Other recommendations contained in the New York report include reduction in the number of cabs, uniform rates and service standards, uniform accounting and reporting, establishment of a city-wide plan of taxicab stands, improvement of labor conditions and establishment of qualifications for drivers. Regulation to carry out these recommendations cannot be enacted until certain legal questions have been settled. Even when this has been done, the process of changing over to a public

Digitized by Google

utility basis may be slow. It is indisputable, however, that the adoption of these recommendations would be a long step toward placing the taxicab business on a sound economic basis and would at the same time assure the public of an improved quality of service.

Compound Ignorance

NOWADAYS when some difficult problem has to be solved it is customary to begin by making a "survey" of the situation. That is generally considered to be a scientific way of securing data on which to base a decision. Sometimes it is, but very often it is not, because the method of collecting the desired information is not calculated to produce accurate results. Too many so-called "surveys" are based almost entirely upon guesswork. For example, numerous parking "surveys" have been based on estimates of merchants as to the volume of business brought to their stores by private automobiles. Their guesses, collected and tabulated, were embodied in a report. This had the appearance of containing information scientifically obtained, but was in reality little more than what has been appropriately called compound ignorance. A survey whereby facts are definitely ascertained is the best possible basis for reaching a decision on a vexing problem, but surveys based on guesswork are valueless.

$9,000,000 Choice for Indianapolis

MONTHS must elapse before the reorganization of the Indianapolis Street Railway is completed, but the preliminaries have been carried out with celerity. The receivership dates back only to April 18 of this year. Yet since then a plan has been evolved which, if it is concluded, will witness the expenditure of more than $9,000,000 over a period of five years. This is a large program. The amount of new money is a sizable sum. Aside from the technical terms of the reorganization, drastic in some respects, interest centers for the time on conditions upon which the new money is to be supplied.

Reasonable protection against any possible recurrence of the events which led up to the present receivership is what the new interests seek. They know that economic forces are at work in which all business must find its level, and they also know that in the past artificial barriers have been raised which militated against the success of the enterprise. If $9,000,000 of new money is to go in, then the company must have reasonable assurance that ability to earn on the readjusted capital shall not be denied. To this end the condition has been set down that the consummation of the plan shall depend upon the procurement of a modern service-at-cost franchise from the city indeterminate as to time. In this respect the proposal follows closely the lines on which similar settlements in Chicago and other cities have been brought about and follows the precedent established by earlier grants in Cleveland, Rochester, Toledo and other cities.

The Insulls, under whose auspices the plan is advanced, have a genius for carrying out rehabilitations of this kind, but they are not magicians. They do not produce something from nothing, although at times the results they have achieved with seemingly hopeless material have been amazing. The Legislature must act on the matter, but if the members of that body and of other bodies charged with civic responsibility are endowed with acumen, they will lose no time in seeking to fulfill their part of the obligation. The spending of $9,000,000 should make the local Indianapolis system one of the finest in the country. After what Indianapolis has endured in the past, there would seem to be only one answer to the choice of the city between the prospect of continued penury for its local transportation system as now constituted and pride at that system's prospects under the plan proposed.

Getting the Most Out of Improvements

WHEN new devices are offered by the manufacturers, emphasis usually is placed on the improvements that can be effected if full use is made of them. For instance, modern railway motors and control can start and accelerate street cars at rates as high as 3 m.p.h.p.s., and do it hour after hour and day after day. Brakes are available that can stop cars even more quickly. These rates are practically twice as great as those standard ten years ago. Other equipment has made corresponding advances in efficiency. The arguments that can be advanced in favor of the use of such modern devices make the progressive manager feel that he cannot afford to get along without it.

But when the new apparatus is bought and placed in service it does not always give anything like the results that were anticipated, and so may become a bitter disappointment. All too often the operating forces, with long training in antiquated methods, fail to grasp the real purpose of the new designs, which is not merely to replace the old with something just as good, but through the use of something much better, to make possible an entirely new plan of service. The men, not used to the new way, sometimes are afraid to see what they can do if full opportunity is taken of the improvement. Again, there is a tendency to make only partial use of it, holding the full value in reserve for an emergency. What they need is careful instruction by men who are fully competent to give it, and who are fully conversant with the possibilities of the new equipment and of its peculiarities as well. The supervisory forces must understand, for instance, that new cars cannot be placed a few at a time on routes on which there are many old cars, so that the new ones cannot show what they can do. So it is with shop tools and devices for track construction.

Sometimes this failure to see that equipment alone cannot effect the improvement is not confined to those in the ranks; it may go through the management. All in authority must be in sympathy with the purpose behind the installation, or the result will be that seen on one property when cars with full safety equipment were purchased some ten years ago on order of the state utility commission. The general manager, asked about the advantages to be obtained, stated that they were questionable, but that in a few months the special devices would be out of order anyway, and then everyone would go about his business and be satisfied. Thus it is easy to see that the cars were doomed to failure even before they were received.

So when improvements are planned it is essential to be sure that everyone from the top to the bottom of the organization is fully "sold" on them and is willing to do his full share in getting the most out of them. Otherwise, there is little value in spending good money for changes that will largely fail of their purpose.

Good Track Layouts Facilitate Routing in Atlanta

On Marietta Street in the downtown business section of Atlanta, the railway department of the Georgia Power Company has several unusually complicated layouts of special trackwork. At the intersection of Marietta and Broad Streets is a grand union. One block to the west is a double track crossing with four connected branch-offs. This layout is further complicated by the necessity to bend the Marietta street tracks outward around a statue located in the center of the street a short distance away from the intersection.

Savings in operating expense have been made consistently in every department of the railway system. As a result, the net has gone up five times in five years

Net Revenue Increased

400 PER CENT IN FIVE YEARS

Is Atlanta's Accomplishment

Large purchases of new cars, improvements in other departments and a general gain in efficiency are features of a ten-year program of modernization that has brought great financial results

FINANCIAL benefits that will accrue from carrying through a program of modernization and adaptation of a transportation system to the needs of the times are well exemplified in the record of the railway department of the Georgia Power Company during the past ten years. Not only have improvements been made, but careful planning has been done in order to get the best results from every expenditure of effort or of money.

Back in 1921, when the present railway management took charge of the property, the system was in relatively poor physical condition, and the operating methods were not of the best, even according to the standards of that day. It was seen at once that a great deal of rehabilitation work would have to be done before it would be possible to give a type of service even approaching that which it was felt must be furnished in order to maintain the revenue at a point which would permit of profitable operation.

One of the first moves of the management was to improve the rolling stock. Accordingly, a purchase of cars was made at once, and a definite program was adopted so that further purchases of modern cars have followed consistently until, today, the average age of the cars on the property is only about seven years. As the new cars were received, the obsolete ones were retired and destroyed. At the end of 1929 there was a total of 405 cars of all types on the property. Most of the 374 active passenger cars included in this total have been bought in the last nine years. Against this, 285 cars have been retired since Jan. 1, 1923.

Soon after the decision to modernize was made, the company began laying out a definite program of improvements. The Beeler organization, of New York City, was engaged to make a detailed study of the property with a view to determining the proper routing, scheduling, and methods of operation to bring the standards up to what it was felt the public demanded. In the main, the changes

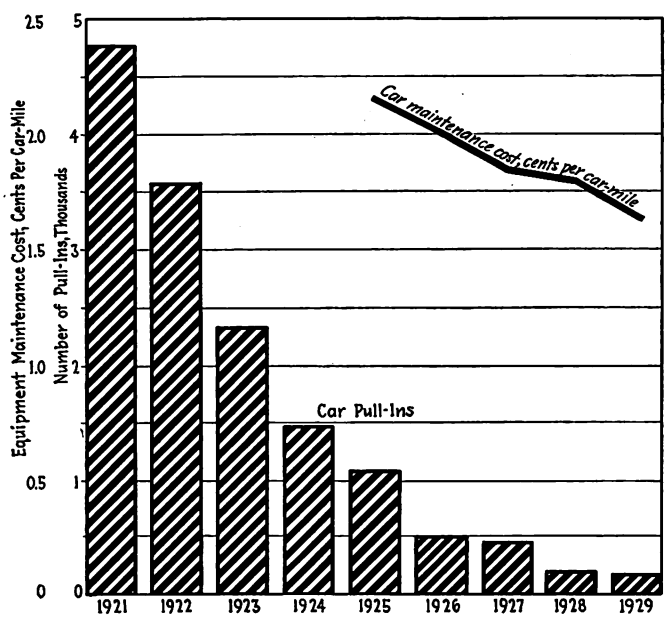
Digitized by Google

that have been made during the past several years have been based on the recommendations contained in that survey. During the entire period the operations of the railway system have been conducted under the leadership of Frank L. Butler, vice-president of the Georgia Power Company and manager of its railway department.

Naturally, the greatest interest in the results centers in the Atlanta division of the railway system. This is by far the largest unit, carrying approximately 90 per cent of the total passengers last year. Operating results for the Atlanta division are given in the accompanying table and chart. With revenues increasing slightly, it has been found possible to reduce operating expenses sharply in every department. The total operating cost last year was approximately 25 per cent less than it was in 1925. As a result, the operating income after taxes has gone up from $321,294 in 1925 to $1,607,166 in 1929, or just five times as much.

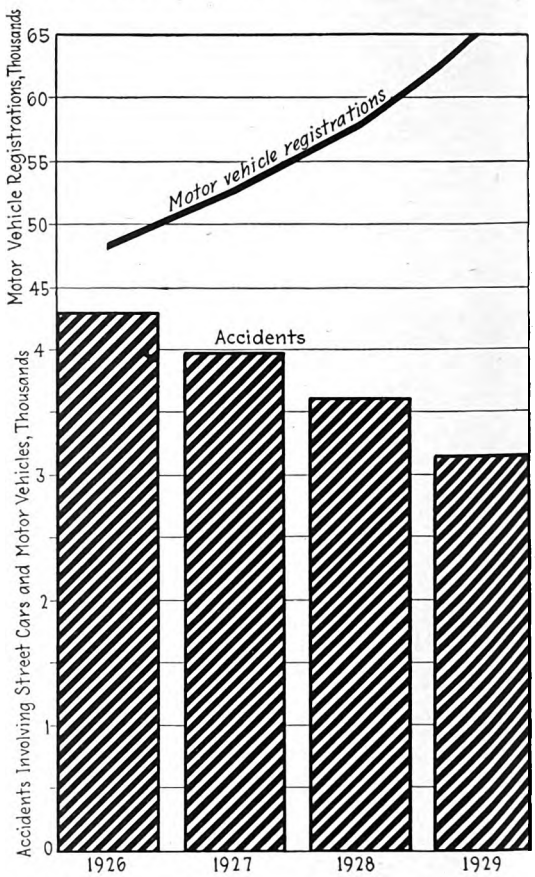
Similar comparisons for the other divisions over the five-year period are not available. The results for 1929 as compared with the previous year, however, show a general improvement, so that the net revenue for the entire railway system has gone up more than $200,000. Of this increase, $25,000 was on the divisions outside of Atlanta.

When looking for the reasons for this remarkable showing, one is struck by the great improvement in operation shown throughout. Of particular importance is the increase in reliability of the car equipment. There has been a progressive reduction in car failures over the five-year period that has brought the company up from one of the poorer ones to the leader in its territory in this respect. Last year there were only 156 car failures as against 169 in 1928. In other words, the cars were operated 83,861 miles per pull-in last year and were maintained at a cost of 1.62 cents per car-mile, as against 77,664 miles per pull-in in 1928 at a cost of 1.79 cents per car-mile. That this was not a sporadic effort was seen in the continuing reduction in maintenance cost per car-mile from 2.15 cents in 1925, and a decrease in pull-ins, the average miles per pull-in that year having been 12,226. The result is shown graphically in one of the charts.



With a remarkable record for reliability of the cars, equipment maintenance costs have been reduced sharply

In connection with the above comparison, it must be borne in mind that, while the car-miles operated have been practically the same from year to year, the motor-miles have increased from 40,424,174 in 1925 to 49,265,076 in 1929 on account of the use of a greater proportion of four-motor cars. Included in the 285 cars retired since 1922 are all of the single-truck cars as well as the older double-truck cars, many of which were equipped with two motors. Some of the cars have been rebuilt and some converted into one-man safety cars.



Accidents involving motor vehicles have gone down despite a large increase in registration in the county

New motors and control have been installed in a number of instances, but purchases of new cars were responsible for the major improvement in reliability and low maintenance cost.

In the way department construction and maintenance work were carried on at about the same rate last year as in the past several years. By careful planning it was found possible to reduce costs below the budget. Roadway payrolls have been reduced from previous years. As an example of the improved quality of workmanship, the electric switches in 1929 made a record of 102,160 operations per failure as compared with 80,271 in 1928. The unit cost of maintaining these switches, however, went down from $55.18 to $44.63, a decrease of 19.1 per cent.

In the conducting transportation account there has been a marked reduction in cost during the past five years. This has come from the gradual introduction of one-man cars, from an increase in schedule speeds, a reduction of accidents and a revision of the personnel for greater efficiency. During the past year the Pryor Street and Central Avenue viaducts were completed and opened for service. Several car lines were rerouted to take ad-

Revenues and Expenses, Atlanta Street Railway Lines of the Georgia Power Company, 1925-1929

Revenues	1925	1926	1927	1928	1929
Passenger	$5,052,378	$5,161,958	$5,034,237	$5,276,705	$5,143,871
All other	82,541	95,356	92,861	86,038	89,737
Total revenues	$5,134,919	$5,257,315	$5,127,098	$5,362,744	$5,233,680
Expenses					
Maintenance	$667,929	$569,232	$529,396	$462,995	$437,427
Renewals and replacement reserve	409,016	443,153	334,315	271,183	227,364
Power	618,590	595,088	618,710	547,034	548,052
Conducting transportation	1,837,931	1,772,888	1,750,061	1,649,817	1,563,511
Traffic	11,702	19,269	1,300	412	1,290
General and miscellaneous	730,881	763,689	518,106	628,758	473,032
Total operating	$4,276,049	$4,163,319	$3,751,888	$3,560,198	$3,250,675
Net revenue, railway operations	858,869	1,093,995	1,375,210	1,802,545	1,982,933
Taxes	537,575	541,579	403,181	370,926	375,766
Operating income	$321,294	$552,416	$972,029	$1,431,619	$1,607,167

vantage of them, saving a number of turns in the center of the city. Enough cars suitable for one-man service have been obtained so that they now are operated in the base service on all city lines but one, on which the fare situation makes their use impracticable.

The changes in methods of operation were made with no labor turnover. Transfers of men from one service to another provided for all the additions and took care of those men displaced by extension of the use of one-man cars. So few men retired, left the service or were discharged that it was not necessary to hire any new men in the transportation department during last year.

The accident situation has shown a marked improvement. In the fall of 1926 accident prevention work was centralized under a safety director. Since then there has been a steady reduction in accidents of all classes from 6,247 to 4,180 in 1929, or 33 per cent. This result has been accomplished while there was an increase in registration of motor vehicles amounting to 33.8 per cent. Nevertheless, all accidents in which street cars and motor vehicles were involved have gone down 27.2 per cent. This result has been accomplished by careful instruction and follow-up work.

Many of the methods which have contributed to the great improvement in operation have been discussed in this paper from time to time. A complete summary of the achievements of the management at the time was given in the brief submitted in the Charles A. Coffin competition in 1927. This brief was abstracted in the JOURNAL, Dec. 31, 1927, page 1180. At that time, the projects were just coming into fruition. Now, three years later, the benefits have not only been retained, but in almost every department the records made then have been exceeded by a wide margin.

Wing plow of the International Railway, Buffalo, pushing back snow to the curb line

SNOW REMOVAL

PROBABLY no emergency condition under which a railway is forced to operate demands faster or more efficient handling than that caused by a snowstorm. Preparedness in organization and equipment for snow removal, consequently, is one of the fundamental efforts of many railways. The following survey of snow-fighting methods used by more than a dozen companies in the United States and Canada shows that such preparation is effective and assures, in nearly every instance, the continuance of normal operation and service.

Notable progress in snow-removal practices has been made during the past two decades, not only by the railways but by city street departments as well. Gradually a closer co-ordination of effort on the part of these two agencies has resulted in a more effective distribution of the work to be done and a more economical use of machinery and labor utilized by each. Yet, under franchises, ordinances and operating agreements the railways continue to bear a great part of the expense of snow removal, not only from their own track areas but from the entire roadways used. A general survey of the operating arrangements in most cities shows that the railways are required to clear the snow and ice from their track areas at their own expense. In addition to this, they are charged a percentage of subsequent removal of the snow by the city's forces. Where this particular arrangement does not exist there is usually an alternative obligation whereby the railways completely clear snow and ice from certain streets and the city uses its equipment and forces on other main arteries.

Various bases and scales are used upon which the charges for subsequent removal, after clearing, are made. In Montreal, the Montreal Tramways is required to pay half of the cost of removal. In Minneapolis, the Twin City Rapid Transit Company under agreement pays $\frac{1}{10}$ of the total cost of the removal of snow on a 40-ft. street, and $\frac{1}{60}$ of the total cost on a 60-ft. street. In St. Paul, this company is required to pay $\frac{1}{8}$ the cost of removing snow from any street on which there is a car line. The Toronto Transportation Commission, after clearing the snow from its tracks, is required to pay $\frac{1}{3}$ of this cost, while, under three fran-

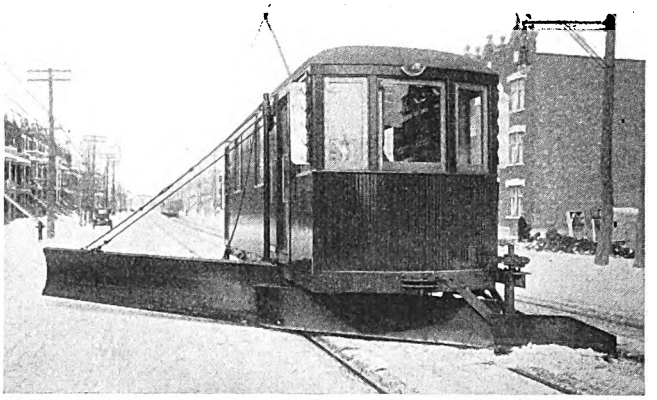
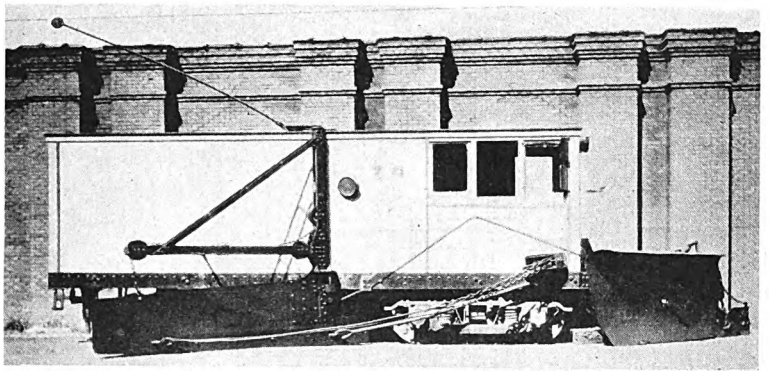
In northern United States and Canada, where the snow and ice problem is greatest, railways are continually improving methods and equipment. Conditions and practices on twelve properties are summarized



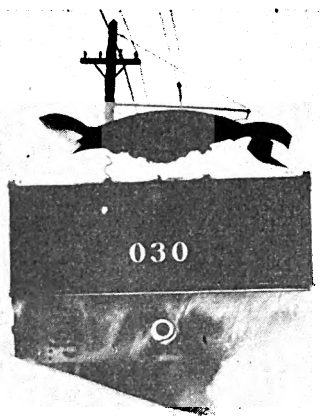
With both wings in action, this plow of the Montreal Tramways clears a path 18 ft. 6 in.



At left — Heavy-duty plow of the Twin City Rapid Transit Company

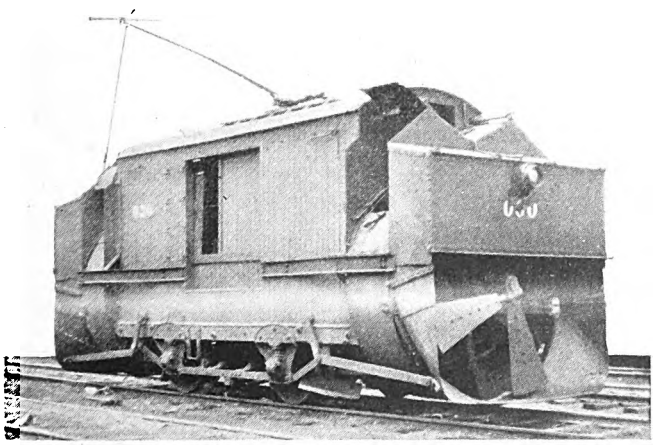
chises, the Duluth Street Railway pays for removal based upon the number of inches of snowfall reported by the U. S. Weather Bureau. Different operating arrangements are listed in the table accompanying this survey.

Because the problem of snow removal is a major one on the properties covered by this study, equipment, such as plows, sweepers and ice-cutters, as well as methods of organizing the actual work itself, has been given the utmost attention. Machinery has been developed to meet extreme conditions and to stand hard work. An example is the equipment used by the Montreal Tramways. Ten single-truck wing plows have been developed to accomplish two main purposes, clearing tracks of snow during storms and cutting down the ice which builds up on the devil strip from time to time during the winter season. With both wings in action, the effective snow clearing path of these plows is 18 ft. 6 in.



Rotary plow in action on the Wilkes-Barre Railway

The essential features of these plows are: (1) The strong, curved steel side wing, pivoted on the heavy vertical shaft at the front of the plow, and adjustable for height as required. This wing was carefully designed so that at operating speed the snow is effectively rolled back to the end of the wing. The wing is power-operated through a clutch on the driving motor by a rack and pinion with a connecting rod with universal joint attached to the back of the wing. This feature permits of easy movement of the wing allowing it to be used to advantage during storms in heavy downtown traffic. (2) The ice cutter on the devil strip, which consists of a heavy steel casting with inserted hardened teeth, is also pivoted on a vertical shaft. This cutter which, when not in use, folds back against the side of the plow, is hand-operated through a vertical shaft and chain



Adjustable hood and blades are features of the Wilkes-Barre rotary plow

Comparative Data on Snow Removal Practices and Equipment

Railway	Operating Obligations Imposed by Franchise, Contract or Agreement	Snow Fighting Equipment Used on Street Car Routes	Materials and Methods Used for Keeping Track and Switches Open	Equipment Used on Bus Routes	Materials and Methods Used on Icy or Slippery Streets	Wages Paid for Snow Removal and Sanding Work
Montreal Tramways Montreal, Canada. Track-miles..... 302 Bus-miles..... 38	Company must keep tracks free from snow and ice. City removes snow from entire street, company paying one-half cost of carting.	35 single-truck sweepers. 7 double-truck sweepers. 2 double-truck rotary plows. 3 single-truck rotary plows. 10 single-truck wing plows. 11 salt cars.	Salt only. Applied by switchmen or hillmen at regular stations. For switches salt is mixed with snow. Salt cars are operated.	None. City cleans and removes snow from bus routes.	City uses cinders and sand, spreading by hand. Company spreads cinders by hand and sand with a mechanical spreader.	5 cents advance on regular rates to all employees on cars for snow removal. Does not apply to hillmen or switchmen.
Twin City Rapid Transit Company Minneapolis, Minn. Track-miles..... 520 Bus-miles..... 110	Company must remove snow from tracks. Under agreement company pays 19/40 of total cost of removing snow from a 40 ft. street and 19/60 from a 60 ft. street. In St. Paul pays ½ cost of removal on any car line street.	19 plows. (Described in survey).	Tracks and switches are thoroughly greased. Salt and gasoline are used for melting snow and ice.	None. City or county removes snow from bus routes.	Sand hauled in a motor truck and spread by hand only on necessary locations.	Regular rates.
Toronto Transportation Commission Toronto, Canada. Track-miles..... 255 Bus-miles..... 570	Commission plows track area. City removes snow from entire street, charging commission one third of total cost.	24 single-end sweepers. 4 double-end sweepers. 2 rotary plows. 4 work cars fitted with blades.	Switches are cleaned and salted at least twice daily.	3 Walter plows with cinder box. 1 Walter plow with wrecker. 1 Walter plow with dump body. 1 Walter plow with sander. 1 Fordson tractor plow. 2 sanders.	Commission cinders all bus stops. City sands hills along street car routes.	2 cents per hour additional to car sweepers and plow operators only; gasoline equipment operators and laborers regular rate. No overtime paid.
Duluth Street Railway Duluth, Minn. Track-miles..... 114 Bus-miles..... 35	Under three franchises, company removes snow and ice from tracks. City subsequently removes snow from entire roadway charging company a sum based on snowfall record of U. S. Weather Bureau.	5 railway plows. 2 double-end detachable plows on street cars. 4 single-end detachable plows on work cars. 3 detachable plows on motor trucks. 1 heavy ice cutter.	Calcium chloride on hard surface streets. Salt on unpaved streets. Applied by hand.	None. City or county removes snow from bus routes.	Cinders, fine gravel or sand. Usually use tire chains only on hilly routes.	Snow equipment crews, regular rates plus 25 per cent. Switchmen regular rates.
International Railway Buffalo, N. Y. Track-miles..... 450 Bus-miles..... 90	Franchise requires company to clear right-of-way and pay 25 per cent of subsequent removal. In practice equipment has been designed to remove snow from curb to curb on car line streets.	30 plows. 23 sweepers. 1 ice cutter.	Sand and cinders used on track. Salt on switches when necessary for melting snow.	18 sanding trucks. City removes snow from bus routes and company follows with sanders.	Spreads sand and cinders by mechanical devices. Under extreme conditions, salt is used.	Two-man rate for platform service plus half time.
Winnipeg Electric Company Winnipeg, Canada. Track-miles..... 121 Bus-miles..... 23	Company responsible for snow removal from tracks and 18 in. outside. If city engineer decides it is necessary, company must clear streets from curb to curb.	10 sweepers. 2 plows.	Sand on rail. Salt in switches for melting snow.	1 motor-driven plow and planers. City responsible for removal but company assists.	Cinders and sand spread at bus stops. Work is done by hand.	Regular rates.
United Electric Railway Providence, R. I. Track-miles..... 263 Bus-miles..... 161	No franchise obligations. Arrangement whereby company cleans and removes snow from certain designated streets and the city others dates back to old franchises.	3 sweepers. 46 plows.	Switches are kept salted during snow storms. Some calcium chloride used.	1 blade plow on a 5-ton truck. 5 sanders. City and county remove snow from bus-routes.	Sand applied by mechanical spreaders.	15 to 20 cents per hour in addition to regular rates. Sanding work for buses done by night track crew at regular rates.
Department of Street Railways, Detroit, Mich. Track-miles..... 435 Bus-miles..... 490	Railway dept. cleans and removes snow from all car and bus routes.	14 sweepers. 11 plows.	Salt.	Walter plows. Handy Andy sand spreaders.	Cinders and salt or sand and salt spread mechanically.	$1.00 per hour as compared to regular rates of 67 cents, 71 cents and 75 cents.
Springfield Street Railway Springfield, Mass. Track-miles..... 133 Bus-miles..... 99	By agreement with city, the company removes snow on certain streets from curb to curb. This is equivalent to total track area throughout city.	11 sweepers. 1 rotary plow. 7 plows.	Salt	None	City sands hills. Work is done by hand.	Time and one half for snow equipment work. Regular rates for sanding.
Cleveland Railway Cleveland, Ohio. Track-miles..... 403 Bus-miles..... 90	No franchise obligations. Company clears snow from track areas. City assists in downtown sections.	28 sweepers. 20 plows.	Salt.	Good Roads Machinery, 6 cu.yd. spreaders.	Salt mixed with sand spread mechanically. In extreme cold calcium chloride is used.	Time and one half for snow equipment work. No increase for sanding or salt work.
Pittsburgh Railways Pittsburgh, Penna. Track-miles..... 592 Bus-miles..... 126	No franchise obligations. City cooperates in downtown congested areas by cleaning snow and ice from street car stops.	39 sweeper cars. 17 scraper cars. 3 Fordson tractor plows. 3 auto trucks with plows.	Switchmen working in two-man crews and equipped with trucks or motorcycles clean and oil switches, spreading salt around them.	None	Granulated slag or cinders and salt mixed.	Regular rate plus 10 cents per hour if during working period. Overtime work, time and one half based on 80 cent per hour rate, extra men time and one half on 70 cent rate.
Eastern Massachusetts Street Railway Boston, Mass. Track-miles..... 610 Bus-miles..... 219	General practice, railway clears snow from tracks and levels at side. In some cases, city does subsequent removal, in others removal is done by railway.	62 plows. 39 sweepers. 1 ice breaker. 21 cars equipped with Root scrapers. 6 cars equipped with rotating broom under body.	Salt.	Best tractors. Walter tractors. Plows attached to trucks.	Sand spread from trucks by hand.	12 cents per hour in addition to regular one man rate. Automotive snow removal done by track or line department at regular rate.

drive. In its working position this wing is braced from the rear by a sliding shaft held by a wooden dog, which will be sheared off if the cutter encounters very heavy ice or some solid obstruction. This permits the wing automatically to fold back to position against the side of the plow. The same protection is provided for the main side wing.

The usual operating height for the wing above the rail level is 2¼ in., but, where street surface conditions are known to be good, this can be reduced to as low as 1½ in. with advantage. The floor of the plow body is weighted with concrete to make available the full tractive effort of the two 50-hp. motors.

During the past winter, an unusually severe snowfall, accompanied by high winds and drifting snow for a considerable period, forced the Montreal Tramways to make improvements on equipment previously used on suburban lines. Deep cuts with vertical sides from 8 to 10 ft. high were formed over several miles of suburban track by the rotary plows. These cuts would be refilled by drifting snow within a very short time after the passage of the rotary. Two special plow equipments were designed with concave wings, 18 ft. long by 30 in. wide. These are hinged from a point about 5 ft. behind the rear truck. A chain tackle, hung from the hinge post, permits of a heavy steel wing being set at any desired angle from the plane of the rails. It can also be swung out at any angle in a horizontal direction, and held in position by chains. The free end of the wing points forward and thus pulls the snow on to the track instead of pushing it away, piling it up behind the rear truck, to be picked up and spread out over a wide area by a rotary plow following close behind.

The vertical sides of the bank, after several passages, are thus transformed into clean, smooth slopes at an angle of about 20 deg. from the horizontal. This contour allows drifting snow to be blown wide across the right-of-way instead of being pocketed between the vertical sides of the cuts. The final cleaning is done with sweepers.

The Twin City Rapid Transit Company has built nineteen snow plows in its own shop. They weigh approximately 80,000 lb. each. Trucks are equipped with four GE-73 motors, geared for slow speeds. The nose of the plow is hinged to a heavy frame in such a way that it can rise when it strikes rough track or hard paving blocks. Immediately back of the nose is a combined scraper and steel broom. Both the nose and the scraper broom are air-controlled, as is also a small extension to the plow nose. On the side of the plow is a large wing which throws the snow about 12 ft. beyond the outside rail. This wing is pulled in and out by means of an electrically operated windlass, and is raised or lowered by means of an air cylinder. Between the front and rear trucks is another air-operated combined steel broom scraper consisting of 5,200 steel cutting points which are very effective in removing ice.

Street signs used in Montreal to warn motorists against parking during progress of snow removal

An ice cutter used by the Duluth Street Railway is shown in an accompanying photograph. It is used on car lines to cut down high ice ridges formed along and between street car rails. The cutter consists of a heavy steel cylinder, with cutter teeth or flanges inserted, which is mounted on a special car truck. This apparatus is either pushed or pulled by snow plows or work cars.

pany's cost for snow removal and sanding per single track mile during 1929 was $210, making the cost per car-mile 0.33 cent.

The average cost per mile of track for cleaning street car routes in Toronto for the past five years, 1926-1930 inclusive, was $799, and the average cost for cleaning bus routes was $576 per mile. The approximate cost per mile for 1930 was $854 for cleaning street car routes, and $633 for bus routes. As compared to this, the Pittsburgh Railways' cost per mile of track per year for removing snow and ice is $31, for sanding track made necessary by snow and ice, $45.

In 1929, the United Electric Railways, Providence, R. I., operated 12,098,000 car-miles and 4,199,000 bus-miles. The total cost of car snow work was $35,084, and of bus snow work $3,359, making the cost of car-mile 0.29 cent and per bus-mile 0.08 cent. The Duluth Street Railway's cost for snow and ice removal during 1929 was 0.34 cent per car-mile. In terms of snow vehicle-miles, the Cleveland Railway snow removal operation cost from 50 to 55 cents per car-mile.

Swiss Scenic Railway Electrified

ZERMATT, the famous Swiss town at the foot of the Matterhorn, is now reached by an electric railroad. The line between Visp (Viege) and Zermatt recently has been electrified. The line was opened with steam power in 1881. At Visp the trains connect with the Swiss Federal Railway electric express trains on the Simplon route, which runs between Lake Geneva and Visp, Brig and Italian points. The electric trains on the Lötschberg route connect the Bernese Oberland with Brig. In order to make a connection with them, the Visp-Zermatt line has been extended from Visp to Brig, and through trains are now operated from the latter point to Zermatt.

A.I.E.E. Meeting Considers Railroad Electrification

Several important papers presented at technical session on this subject. Inspection trips made to important projects in Philadelphia and vicinity

RAILROAD electrification was one of the major topics at the sixth Middle Eastern district convention of the American Institute of Electrical Engineers held at Philadelphia, Pa., Oct. 13-15. One entire session was devoted to the subject, and several inspection trips were made to local installations.

Six important papers were presented at the technical session on electrification held Wednesday morning, which was presided over by G. I. Wright, engineer electric traction the Reading Company.

C. L. Doub, assistant engineer of the same company, presented a discussion of the power supply facilities for the suburban electrification which is now being installed by the Reading in Philadelphia and surrounding territory. The facilities are being planned so that the electrification may readily be extended to include through passenger and freight service between Philadelphia and New York City, Bethlehem and Reading, Pa. Contract has been made with the Philadelphia Electric Company for initial power requirements, and provisions are made for enlarging such supply to serve all of this territory.

The railroad is constructing substation and transmission facilities to serve the suburban territory by a 12,000-24,000-36,000-volt, three-wire, single-phase, 25-cycle distribution system, with the view to reaching the more remote area by superimposing 66,000-volt transmission lines upon the initial system at the time of future extensions. The present and proposed layouts are described in the paper together with the estimated power requirements and the manner in which the railroad system is to be served from the power company network.

Utilization of railroad right-of-way for electric power transmission and co-ordination with railroad electrification was the subject of a paper by W. W. Woodruff, superintendent of aerial lines Philadelphia Electric Company, and G. I. Wright, engineer electric traction the Reading Company. It was pointed out that the use of the Reading right-of-way made feasible the entrance into the heart of Philadelphia with overhead transmission at high tension of the power required for many industries. The difficulties that were encountered and the financial and management problems that had to be solved were considered in some detail. It was pointed out that a prime requirement was that the operation of the railroad or its future expansion should not be hampered, while the electric companies interested should obtain a permanent right-of-way where the securing of an independent route would be practically out of the question.

Steps taken in initiating the Pennsylvania Railroad electrification in the Philadelphia district were explained in a paper by H. C. Griffith, assistant electrical engineer of that railroad. The operating practice, the functions of the power director and those associated with him in switching and grounding circuits for safeguarding the personnel were discussed.

Other papers presented included a description of the substations for the new Broad Street subway by H. M. Van Gelder, electrical engineer department of city transit, Philadelphia; use of oil-electric or gas-electric locomotives and motor cars as an adjunct to electrification, by A. H. Candee, Westinghouse Electric & Manufacturing Company; and modern single-phase motors for railway electrification, by F. H. Pritchard and Felix Konn, General Electric Company.

Following the presentation of the papers, a lively discussion took place. Sidney Withington, New Haven Railroad, called attention to the rapid development of mercury vapor rectifiers for railway service within the year, mentioning particularly their use on the Lackawanna. While use of the railroad right-of-way for power transmission is very interesting, he feels that the railroads must be careful not to permit construction that will in the future impose restrictions on track developments. In connection with the load curves for the Reading shown by Mr. Doub, he pointed out that the load factor of an electrification can be increased greatly by inclusion of freight service, most of which is handled in the non-peak hours.

J. V. B. Duer, electrical engineer Pennsylvania Railroad, sees only a small field for self-propelled cars on electrified systems. The improvements in single-phase motors he considers are of great importance.

J. H. Davis, electrical engineer Baltimore & Ohio Railroad, regretted that no reference was made in the papers presented to inductive co-ordination. In the future, greater attention will be given to the joint use of railroad rights-of-way, he believes.

Other speakers taking part in the discussion included R. A. Hentz, Philadelphia Electric Company; H. L. Andrews, General Electric Company; F. H. Shepard and C. E. Skinner, Westinghouse Electric & Manufacturing Company; F. W. Harvey, Gibbs & Hill; H. M. Van Gelder, city transit department, Philadelphia, and J. J. Linebaugh, Jackson & Moreland.

On Tuesday afternoon, the Pennsylvania Railroad placed a special train at the disposal of the delegates, and an inspection was made of the improvements in the Philadelphia district, including the new passenger station and the Lamokin Street substation. Wednesday afternoon the Reading Company provided a special train for inspection of the progress of its electrification, the trip including the overhead construction between Reading Terminal, Wayne Junction and Jenkintown, the substation of the Philadelphia Electric Company at Plymouth Meeting, and the 66,000-volt transmission line of the latter company over the Reading tracks between Conshohocken and Philadelphia. At Oreland, a demonstration of stringing trolley for a two-wire catenary system was given.

The attendance at the meeting was more than 500.

Multiple-unit electric trains of this type on the Lackawanna Railroad operate on schedules 25 per cent faster than those of the former steam trains

SCHEDULED SPEED

Increased by Electrification

Rapid acceleration and braking rates of new electric trains have enabled Lackawanna Railroad to reduce running time by approximately 25 per cent between Hoboken and stations in suburban zone. Free running speed also higher than that of steam trains formerly operated

SUBSTANTIAL reductions in running time in electrified suburban service were made by the Delaware, Lackawanna & Western Railroad on Sept. 28, coincident with the change from daylight-saving time to Eastern standard time. This increase in scheduled speed has been made possible by the rapid acceleration and braking rates of the new multiple-unit electric trains, as well as their higher free running speeds as compared with the steam trains formerly operated.

The new schedules affect the electric service between Hoboken and South Orange on the main line, and between Hoboken and Montclair on the Montclair branch. Substitution of electric trains for steam trains on the Montclair branch began early in September, and was completed about the middle of the month. The changeover of the Hoboken-South Orange service on the main line was then commenced. This was completed just prior to the inauguration of the new schedules. Steam operation has been continued for the present to points west of South Orange, and no change has been made in running time. It is expected that electric service will be in operation on the main line as far as Dover and on the Passaic and Delaware branch to Gladstone by about the first of next year. Faster schedules will then be inaugurated for these services.

With the change in schedules, the average running time westbound between Hoboken and Montclair was reduced from 34 minutes to 27 minutes, which is equivalent to an increase in speed from 23.1 m.p.h. to 29.2 m.p.h. The running time of the fastest train was reduced from 27 minutes to 21 minutes, with a corresponding increase in speed from 29.2 m.p.h. to 37.5 m.p.h. Eastbound, the average running time was reduced from 30½ minutes to 26 minutes, with a corresponding increase in average speed from 25.8 m.p.h. to 30.1 m.p.h. The running time of the fastest express from Montclair to Hoboken was reduced from 23 minutes to 19 minutes, while the speed was increased from 34.2 m.p.h. to 41.3 m.p.h.

It will be noted that the average time saving is greater in the westbound service than in the eastbound, being seven minutes in one instance and only 4½ minutes in the other. This is due to the fact that there is a fairly heavy grade westbound between Newark and Montclair. The greater ease of starting the multiple unit electric trains as compared with the steam trains has made possible a considerable saving in time westbound. On the east-

†Four additional trains start at points east of Montclair.

bound down grade this advantage is less clearly evident. Despite the greater improvement in westbound running time, however, the average speed eastbound remains somewhat higher than the average speed westbound on the new schedule as it was on the old.

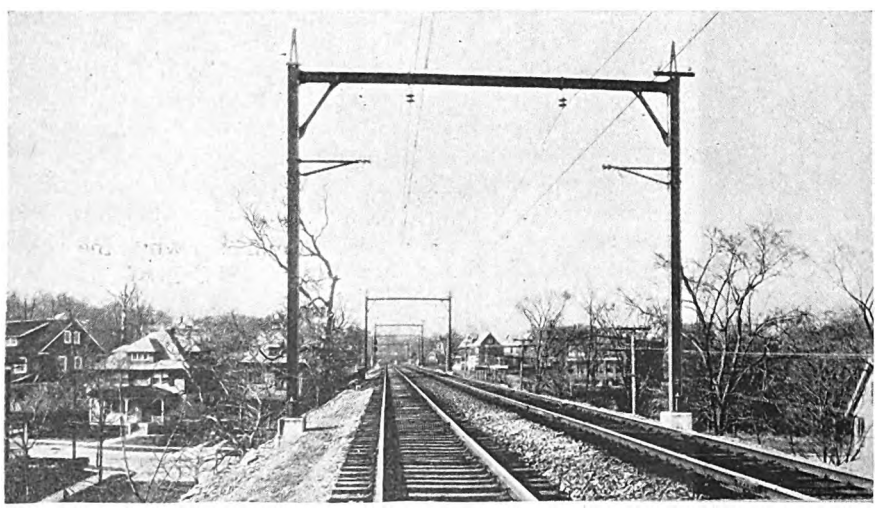
In the South Orange service, the average running time westbound has been reduced from 37½ minutes to 28½ minutes, corresponding with an increase in speed from 22.3 m.p.h. to 29.3 m.p.h. Eastbound the running time has been reduced from 36½ minutes to 27½ minutes, while speed has increased from 22.8 m.p.h. to 30.2 m.p.h. The running time of the fastest train was cut from 32 minutes to 24 minutes westbound and from 31 minutes to 24 minutes eastbound. Speeds were increased from 26 m.p.h. westbound and 27 m.p.h. eastbound, to 34.8 m.p.h. in both directions at present.

From these figures it will be seen that there is a saving of nine minutes in average running time in both directions for the South Orange service. This is somewhat greater than the saving for the Montclair service, because there are more intermediate stops where the advantages of multiple-unit operation are experienced. Between Newark and South Orange there is a slight grade westbound, enough to cause a slight difference in eastbound and westbound speeds, but not so pronounced as on the Montclair branch.

Generally speaking, the changes effected on the new schedules have reduced the running time approximately 25 per cent. This saving is utilized by the westbound trains to reach their destinations earlier. The eastbound trains, on the other hand, are scheduled to leave later and to arrive at Hoboken at approximately the same times as before.

The new schedules call for the operation of a substantially larger number of trains than were in operation a year ago. On the Montclair branch the number of daily trains westbound has been increased from 35 to 38, the additional trains being scheduled between 8 o'clock in the evening and midnight. The number of eastbound trains remains at 37. In the electric service between Hoboken and South Orange, the daily number of trains remains 26 in each direction, as it was on the old schedule. Many trains operating to points west of South Orange, however, serve also the territory between that station and Hoboken. In this connection it should be noted that a total of 38 additional trains were placed on the schedule last spring when electrification was under way but before electric trains commenced operation. These 38 trains have all been retained on the new schedule.

The increased comfort of travel as a result of electrification is marked and has elicited much favorable comment. The existence of a long tunnel just west of the Hoboken terminal was always an element of discomfort with the steam service, because headways were too short to allow the locomotive smoke and gases to leave the tunnel in the intervals between the passage of trains. This difficulty has been almost entirely eliminated with electric operation. Moreover the electric service is much cleaner and quieter than the steam service. This improvement is greatly appreciated both by the passengers and the residents of the towns along the line.



Suburban communities on the Lackawanna Railroad between Hoboken and South Orange and on the Montclair branch now have electric service

Some of the 20,000 taxicabs operated in the City of New York

Regulation of Taxicabs *as a Public Utility* RECOMMENDED IN NEW YORK

Report by Mayor's commission urges operation under a single franchise in co-ordination with all other transit agencies, and advises the issuance of certificates of convenience and necessity to a limited number

ESTABLISHMENT of the taxicab industry in New York City as a public utility, under the jurisdiction of a bureau of taxicab control in the Board of Transportation, was recommended in a comprehensive report made public recently by Mayor Walker's commission on taxicabs. The report recommends operation under a system of certificates of public convenience and necessity, to be issued by the new bureau to individuals and organizations who comply with strict standards of financial responsibility and public safety outlined in the report.

The report expresses the commission's strong conviction that the ultimate solution of the taxicab problem is is operation under a single franchise in co-ordination with all other local transit agencies. It urges that its recommendations be carried out with this goal in view. For the present, the report explains, the certificate system is advocated in order to protect the rights of thousands of owner-operators now engaged in the industry and to give them an opportunity to prepare for future changes.

Single Franchise Urged

The commission's belief in operation under a single franchise as the real cure for the present evils of the industry is voiced repeatedly. It is found in a "summary of conclusions" and also an "outline of facts" which are incorporated as separate divisions of the document. The certificate system is frankly described as a stepping

Digitized by Google

stone to a franchized monopoly, delayed out of consideration for the nearly 10,000 individuals now gaining a livelihood by operating their own cabs.

The commission on taxicabs was appointed by Mayor Walker last Spring after he had vetoed the Board of Alderman's taxicab ordinance which sought to increase the prevailing rates. It is headed by Frank P. Walsh, its other members being Leonor L. Loree, Philip Le Boutillier, Col. George W. Mixter and Daniel L. Reardon. The commission was assisted in its work by Leland Olds, economist, and J. I. Metcalfe, engineer. Its investigation of the industry in New York and in other cities is regarded as the most thorough ever undertaken by a municipality.

Among other things, the report recommends restriction of the number of cabs operating on the city's streets, adoption of the prevailing rate of 15 cents for the first quarter-mile and 5 cents for each succeeding quarter as a uniform rate, and the raising of the annual license fees for cabs to $50 and those for drivers to $10 a year.

The granting of certificates of convenience and necessity only to those operators who can show financial ability to meet all liabilities, as well as ability to operate on sound business lines is urged. It is also recommended that the Board of Transportation bureau have wide regulatory power. The bureau would have the power to fix uniform rates and service standards, grant and revoke certificates, approve and revoke transfers of certificates, and determine prior rights on cab color schemes, the adoption of which is suggested as a preliminary requirement for a certificate. The report also urges that the bureau be empowered to investigate accidents, prescribe submission of regular reports and adoption of a uniform system of accounts by certificate holders, establish a hack stand program, set up conditions of labor and qualifications for drivers, conduct investigations, and, in general, exercise all power required for effective regulation of the industry.

Would Reduce Number of Cabs

An important recommendation of the commission calls for issuance of certificates to the 19,000-odd cabs now operating, but terminable to them when they go out of business, that period in no case to exceed three years. The report suggests that about 14,000 cabs are sufficient to meet the city's present needs.

A preliminary statement embodied in the transmitting letter which sent the report to Mayor Walker described the general situation found by the commission as the result of twelve public hearings, held during the past summer, and the private investigations which followed.

"Your commission finds the taxicab industry in New York City to be in a thoroughly unhealthy condition," the statement declares. It goes on to say that this condition causes many otherwise avoidable accidents, and places the industry largely in the hands of irresponsibles unable to finance the liability for such accidents. Labor instability is also attributed to the present system of operation. Declaring that drastic changes in organization must be made to cure existing ills, the statement adds that the industry "must be encouraged in its inevitable transition to a full grown member of the public utility family."

The report is a voluminous document, including not only the commission's conclusions and recommendations, but also a mass of detailed evidence upon which they are based. These data cover exhaustive studies of conditions in all large American cities and the principal foreign municipalities where taxicab operation is an important transportation factor. This part of the report treats in detail such elements of the taxicab industry as general organization, accidents and safety, cruising and hack stands, rates of fare, the "purpose-built" cab, the cab industry as a public utility and the problem of cab transportation as part of a unified system.

Important Recommendations Made

Among the specific recommendations contained in the report are the following:

That the taxicab industry of New York City be declared to be a public utility and be placed under the jurisdiction of a taxicab control bureau in the Board of Transportation, with authority to assure proper control of the entire industry.

That operation of taxicabs on the streets of New York City be subject to the grant of a certificate of public convenience and necessity issued by the taxicab control bureau on the basis of conditions subsequently enumerated, with power of revocation.

That existing cab owners' licenses to operate cabs on the streets of New York City be granted such certificates covering the operation of cabs now operated, but terminable as to each such cab with its life, and not in any case for more than three years.

That where there is failure to operate any cab for any reason over a period of 60 days or, at the end of the three-year period, the certificate covering the operation of that cab shall lapse and shall be awarded as a new certificate only to the operation capable of demonstrating that public convenience and necessity require such additional cab and that it possesses the ability to utilize it economically and efficiently.

Requirements for Certificate

That the granting of new certificates be based upon demonstrated need for the number of cabs for which certificates are requested as well as upon the operator's establishing the following: ability to assume full financial responsibility for all liabilities incurred; ability to conduct an efficient and economical operation along good business lines; and the adoption of a color scheme or emblem, or both, not encroaching on the established good will of any operation.

That the taxicab control bureau given jurisdiction over the industry be given power to: grant and revoke certificates of public convenience and necessity as defined above; approve and revoke transfers of certificates of convenience and necessity; fix uniform rates and service standards, starting with the 15-5 rate; prescribe the submission of regular reports from all taxicab operations; require a uniform system of accounts to be kept by all taxicab operations; investigate accidents; establish specifications for taxicabs and their condition, including safety equipment, taximeters, etc.; prepare a program for hack stands and establish methods of operation which will eliminate unnecessary cruising; establish employee working conditions necessary to safe and efficient operation, and establish qualifications for drivers.

That the hack bureau of the Police Department shall be continued with its present organization and powers.

That certificates of convenience and necessity issued by the taxicab control bureau be assignable with the consent of such body, but that in no instance shall this body give its consent to such assignment where the consideration for the transfer is in excess of the price fixed by the regulatory body.

That a single rate of fare be established for all taxicabs operated in the city of New York and that for the present this be the prevailing rate of 15 cents for the first quarter-mile and 5 cents for each succeeding quarter-mile, with prevailing extras.

Present System Assailed

The commission's recommendations are based on an elaborate set of findings of fact, which, in turn, is summarized in a set of conclusions embodied in the report. The report declares that the taxicab industry here is, from a business standpoint, one of the most poorly operated industries of its size in the country, due mainly to excessive competition among the nearly 10,000 separate owners who operate its 19,500 cabs.

The conclusions describe as an outstanding evil the fact that there are 68,397 drivers for 19,507 cabs, with a resulting high labor turnover. This, the report asserts, undermines the safe and efficient conduct of the

Digitized by Google

industry. Excessive cruising is found to be a significant factor in the way of safe and economical operation.

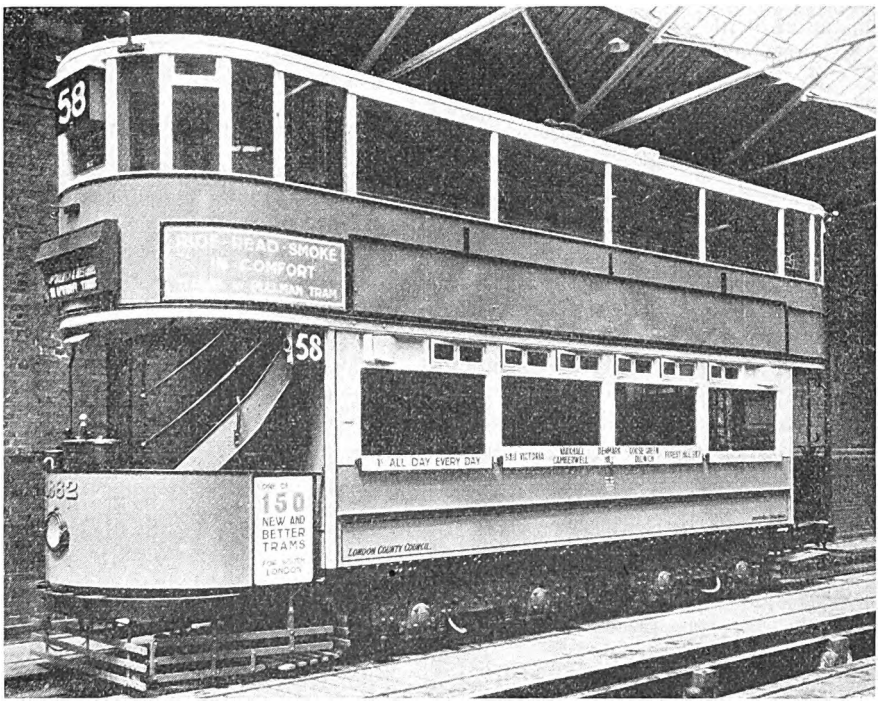
On the basis of the facts brought out in its investigation, the commission finds the present prevailing rate to be adequate if 50 per cent paid mileage can be obtained. Placing of the industry on a business basis, with unnecessary costs to present disorganized conditions eliminated, would make possible lower operating costs, which could be shared with the public either in better service or further reductions in fare, the commission finds.

After describing the magnitude of the industry, with its 346,000,000 passengers a year and its annual income of $144,000,000, including tips to drivers, the commission comes to the conclusion that it must be recognized as "a full-fledged public utility" with proper organization and public control.

"The unifying of the city's taxicab service under a single franchised corporation," the commission finds, offers manifest advantages, many of which cannot be fully attained so long as diversity of operation remains. The advantages of unified operation in terms of economical utilization of cabs and reduction of traffic congestion are especially noteworthy.

"The possible advantages of co-ordinating taxicab operation with the city's general rapid-transit system should be further explored. In Philadelphia, Kansas City and Grand Rapids, such co-ordination has been adopted as a definite public policy, while the trend seems to be in that direction in Cincinnati. The theory is that the general transportation needs of a city can be most economically and satisfactorily met by the combined operations of all transit facilities, in which each supplements the other in resources and services."

L.C.C. Trams Get Low-Level Cars



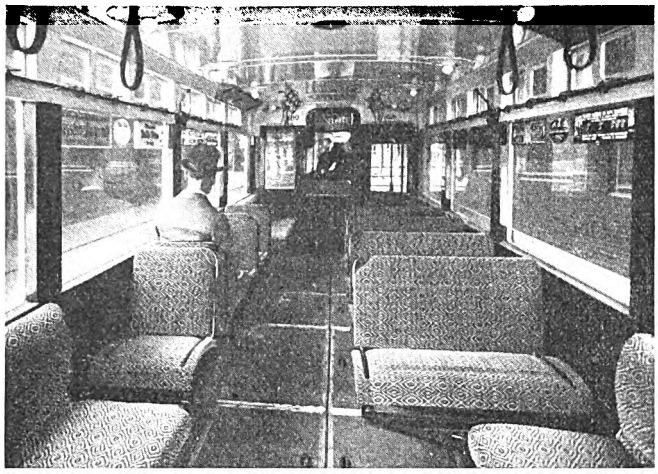
One of the new tramcars just put in service by the London County Council Tramways

DOUBLE-TRUCK tramcars of a new type have recently been placed in service in South London by the London County Council Tramways. Of the 150 cars ordered, 100, designated as Class E-3, are equipped with two motors on maximum traction tracks for fairly level routes, and 50, of Class HR-2, have low-level four-motor trucks for use on hilly routes. The bodies of all are alike.

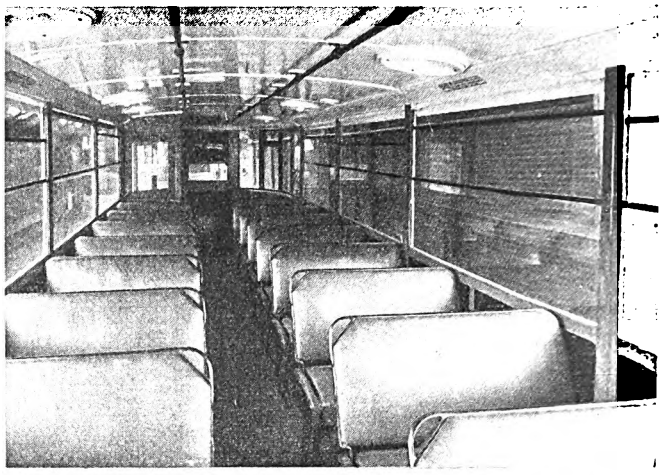
The cars are a development from the type tried experimentally last year. The general arrangement is shown in the illustrations. They are of the double-deck type, 33 ft. 10 in. over-all, and arranged for two-man operation. Each car seats 74 passengers, 28 on the lower deck and 46 on the upper deck. In the lower salon the upholstering is L.C.C. standard moquette, while on the upper deck a non-inflammable red leather substitute is used. On both decks, the floor is covered with battleship linoleum. The headlining is made of $\frac{3}{8}$-in. plywood. The side framing on the lower deck is of teak wood with interior finish of Honduras mahogany. On the upper deck the framing is made almost entirely of interchangeable die castings in Alpax metal, having high tensile strength. The outer panels for the roof covers consist of hard-rolled sheets of aluminum alloy in one width.

The outside paneling of the upper deck is of high

Digitized by Google



Wide windows and comfortable seats are features of the new cars. This illustration shows the lower deck



The upper decks of these new cars are totally inclosed and are fitted with upholstered seats

tensile aluminum alloy plate while the lower paneling is of mild steel plates, forming stiffening members for the car framing. The under-framing and main side posts are of pressed steel sections, electrically welded with supplementary rivets or bolts at points of severe strain.

Non-shatterable safety glass is used for windows and panels that are most liable to damage. Roller curtain destination signs are installed in the ends of the car.

For the 100 Class E-3 cars standard maximum traction trucks are used. The 50 Class HR-2 cars have swiveling trucks with wheels of equal size. All the journals are fitted with SKF roller bearings. The motors are also fitted with roller bearings of the same make. The wheels of the four-motor cars are 26½-in. diameter, mounted on 4½-in. axles. The truck wheelbase is 4 ft. 9 in., and the distance between truck centers is 11 ft. The minimum radius of curvature around which the cars will pass is the L.C.C. standard of 40 ft.

Each of the HR-2 cars carries four Metropolitan Vickers No. MV-109 motors, rated 30 hp. at 262½ volts, the pair of motors on one truck being connected in series. The E-3 cars have two English Electric DK-126-A motors, each rated 57.5 hp. at 525 volts.

The controllers of the class E-3 cars were built by the English Electric Company. They are of the two-motor series parallel cam-operated contactor type, with magnetic brake. The controllers of the HR-2 cars were manufactured by the Metropolitan Vickers Electrical Company. They differ from the others in being arranged for four motors.

Details of the equipment are given in the accompanying table.

Buenos Aires' New Subway

WORK on the first section of the new underground railway which will run from the Buenos Aires Central Railway station to the port at Callao is rapidly nearing completion. The first 4½-mile section was opened recently. The length when the line is completed will be 5½ miles. The subway, which is being built by the Buenos Aires Central Railroad & Terminal Company, is expected to carry 200,000 passengers a day with an estimated revenue of £300,000 a year. Delivery of the entire order of 56 cars for the system will soon be completed.

Specifications of the 150 New Cars for London County Council Tramways

E-3 UNITS

Number of E-3 units	100
Type of unit	Double-deck, two-man, motor, passenger, city, double end, double truck
Number of seats	74; 46 up—28 down
Builder of car body	Hunt Nelson & Co., Ltd., Motherwell, Eng.
Date of delivery	1930
Bolster centers	10 ft. 4½ in.
Length over all	33 ft. 10 in.
Length over body posts	22 ft. 2 in.
Truck wheelbase	4 ft. 6 in.
Width over all	7 ft. 1 in.
Height, rail to trolley base	15 ft. 7 in.
Body	Semi-steel
Roof	Arch
Doors	End
Brakes	Magnetic
Armature bearings	Roller
Axles	5 in. and 4 in.
Car signal system	Atmospheric air type
Control	English Electric Co. series-parallel
Destination signs	Illuminated curtain
Floor covering	Battleship linoleum
Gears and pinions	20 deg. involute
Glass	Non-shatterable in exposed parts
Headlining	⅜-in. Tucker plywood
Interior trim	Honduras mahogany below; light and antique oak above
Journal bearings	Roller
Journal boxes	SKF
Lamp fixtures	Silvalux, 10 in. lower, 10 in. upper deck
Magnetic brakes	Estler Bros., Ltd.
Motors	Two English Electric No. DK-126A, outside hung (57 5 hp.)
Painting scheme	Vermilion and cream
Roof material	Aluminum alloy sheets
Sash fixtures	"Windsor"
Seats	G.D. Peters & Co.
Seating material	Moquette below; leather cloth above
Steps	Stationary
Trucks	Electro-Mechanical Brake Co., Ltd.
Ventilators	4 Ashanco and Venturi air-extracting units
Wheels, type	Steel, diameter 31¾ in. and 21¾ in.
Wheelguards	Hurst, Nelson & Co., Ltd.

HR-2 UNITS

Number of HR-2 units	50
Type of unit	Double-deck, two-man, motor, passenger, city, double end, double truck
Number of seats	74; 46 up, 28 down
Builder of car body	English Electric Co., Ltd., Preston
Date of delivery	1930
Bolster centers	11 ft. 0 in.
Length over-all	33 ft. 10 in.
Length over body posts	22 ft. 2 in.
Truck wheelbase	4 ft. 9 in.
Width over-all	7 ft. 1 in.
Height, rail to trolley base	15 ft. 7 in.
Body	Semi-steel
Roof	Arch
Doors	End
Brakes	Magnetic
Armature bearings	Roller
Axles	4½ in.
Car signal system	Atmospheric air type
Control	Metropolitan-Vickers Co.
Destination signs	Illuminated curtain
Floor covering	Battleship linoleum
Gears and pinions	Helical
Glass	Non-shatterable in exposed parts
Headlining	⅜-in. Tucker plywood
Interior trim	Honduras mahogany below; light and antique oak above
Journal bearings	Roller
Journal boxes	SKF
Lamp fixtures	Silvalux 10 in lower, 10 in upper deck
Magnetic brakes	Estler Bros., Ltd.
Motors	Four Metropolitan-Vickers No. MV-109, inside hung (30 hp.) two in series on 525 volts
Painting scheme	Vermilion and cream
Roof material	Aluminum alloy sheets
Sash fixtures	"Windsor"
Seats	G. D. Peters & Co.
Seating material	Moquette below; leather cloth above
Steps	Stationary
Trucks	Electro-Mechanical Brake Co., Ltd.
Ventilators	4 Ashanco and Venturi air-extracting units
Wheels, type	Steel, diameter 26½ in.
Wheelguards	Hurst, Nelson & Co., Ltd.

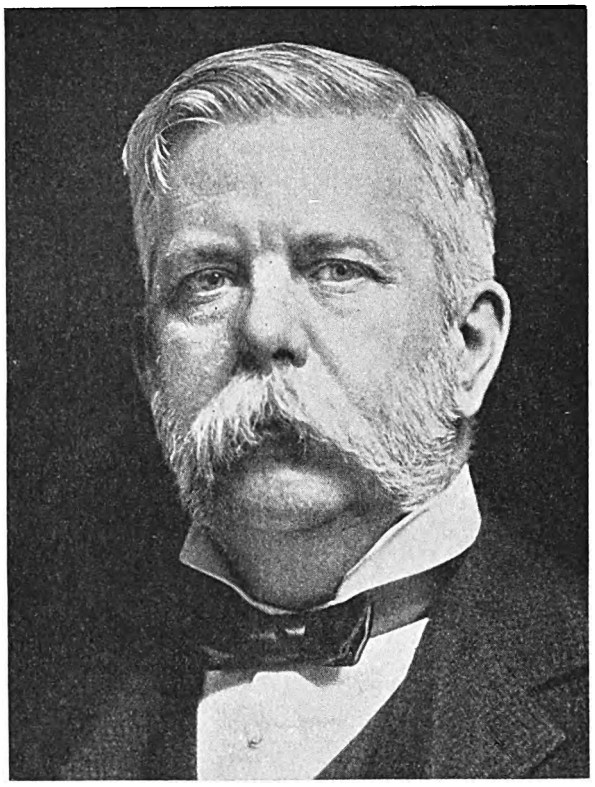
Memorial to

George Westinghouse

Citizen, Inventor and Benefactor of Humanity



George Westinghouse

IN A WOODED GLEN in Schenley Park, Pittsburgh, and before a striking bronze group which is an outstanding contribution to modern art, leaders in every activity of American life paid their respects on Oct. 6 to the memory of one of its most brilliant empire builders—George Westinghouse, inventive genius who produced some of the greatest safety devices of modern times, helped to make the electrical age possible and about these accomplishments built industries which today employ more than 70,000 people in the United States, Canada, Europe and the Orient.

The memorial consists of seven great panels and a statue. It represents the finest efforts in present-day sculpture and architecture. Daniel Chester French, foremost among modern sculptors, contributed the best of skill and genius to produce the figure of American Youth and the main panel. Henry W. Hornbostel, designer of the Harding Memorial, the Hellgate Bridge, and many prominent public buildings, arranged the beautiful setting of the Memorial. Paul Fjelde, a rising young Italian sculptor, produced powerful, striking bronze records of Westinghouse's six greatest mechanical achievements.

At the dedication more than 800 men and women were grouped at the entrance to the ravine in which the memorial was erected. Before them, bordered on both sides by the broad green of two weeping willow trees, was a lily pool. Beyond it, against a background of rocks and the first color of the fall foliage, was the memorial. There is a large central panel flanked by two semicircular wings, all in gold-leafed bronze, with base and insets of black Norwegian granite. In a medallion on the central panel George Westinghouse leans over his drawing board. On either side stand life-size figures in full relief—a skilled mechanic and an engineer with his slide rule. Each of the flanking wings bears three panels depicting in low relief the major events in the career of Mr. Westinghouse. Then, before the monument, placed well back from the panels, stands a bold figure of American Youth, the work of Mr. French. Just a boy it is, in knickers and sweater, his schoolbooks under his arm, who gazes with eager, reverent interest upon this inspiring testimonial to creative genius.

The host of distinguished guests, leaders in the electrical and railway industries, the financial and business world, massed about the speakers' platform made a vivid scene. It was impressive because this throng had come together to honor not only a great man but the ideals and qualities of greatness which that man personified. Through the characteristics of his life and work, therefore, this shrine of George Westinghouse becomes "a monument to the dignity of labor and the supreme glory of service." It is a symbol of the faith, courage and spirit of man that have built the industrial empire.

Incidents in the story of the life of George Westinghouse were reviewed by eloquent speakers in the program of dedication and at the banquet of 700 guests of the Westinghouse organization which assembled at the William Penn Hotel in the evening.

As one of the commentators of the unveiling said, it is impossible to measure George Westinghouse in terms that apply to ordinary men. He patented more than 400 inventions, but he was not primarily an inventor. He founded scores of successful companies, but he was in no sense a promoter. He made millions for himself and others, but he cared nothing for money for its own sake. He directed many vast engineering undertakings, but he cannot be considered merely an engineer. He was one of the most impressive figures, one of the most dynamic forces of his generation, and he applied his gifts and his ability for the benefit of humanity. He contributed greatly to the material development of his country and the world at large and, because of the universality of his work and genius, belongs not only to America, but to the world.

The memorial in Schenley Park is an expression of the pride and veneration of the many thousand Westinghouse employees who contributed to a fund to do honor to this great man. And the occasion in itself was a recognition and a tribute such as have seldom been given in the history of industrial progress.

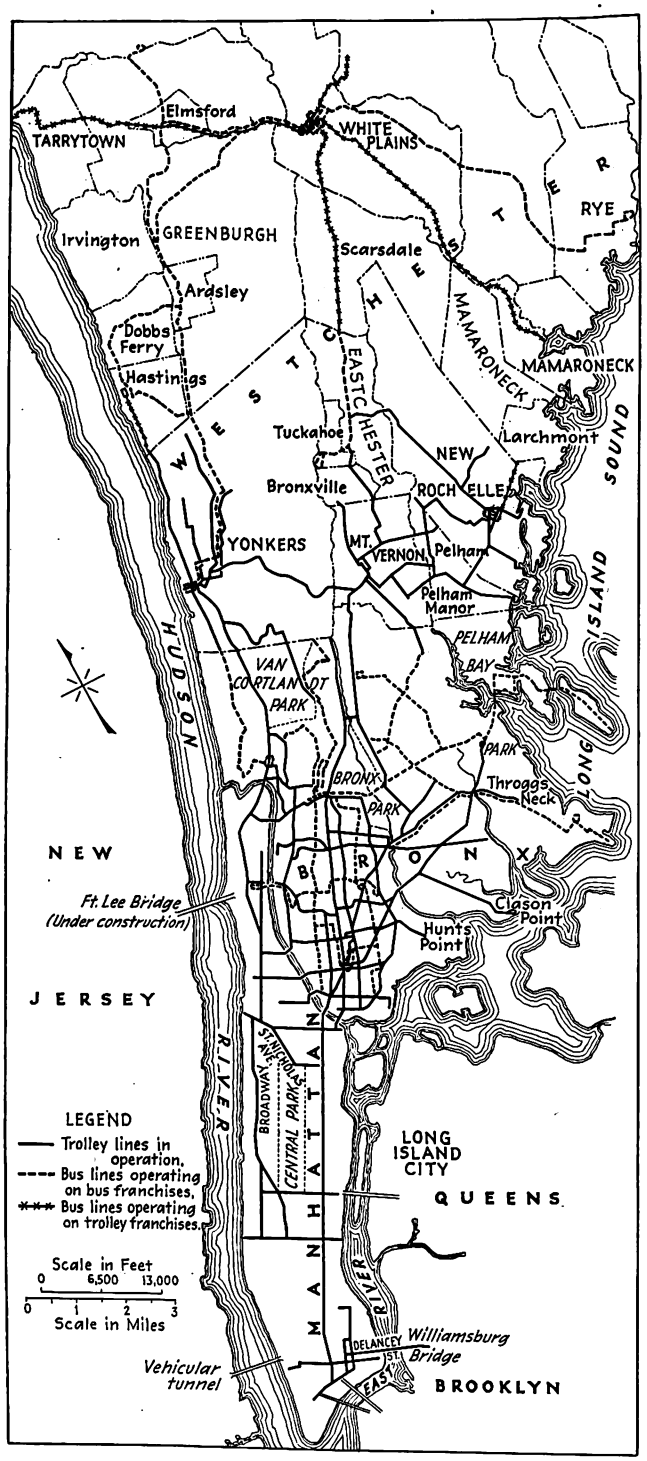
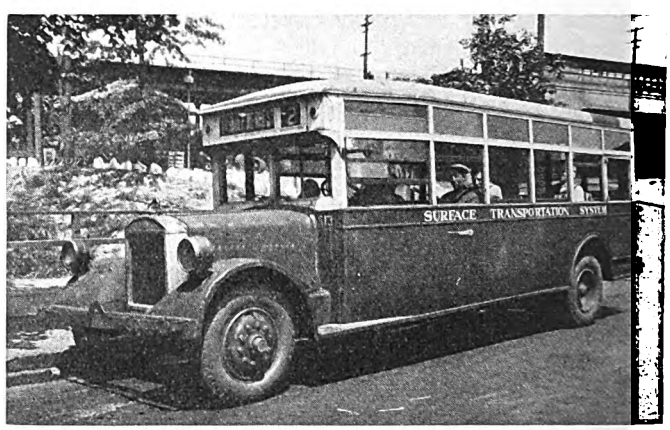
Co-ordinated Bus Operation

INCREASES

Supplementary and feeder service in the Borough of the Bronx and partial replacement service in Westchester County have gained new riders. At the same time street car gross revenue has increased



Bus operations of the Third Avenue Railway System are divided into two distinct units. Twelve routes in the Bronx are effectively co-ordinated with street car service in that borough. In Westchester County general substitution of buses for cars has been made. Further expansion of bus operations in southern Westchester County is under consideration.



A 23-passenger bus used for shuttle service

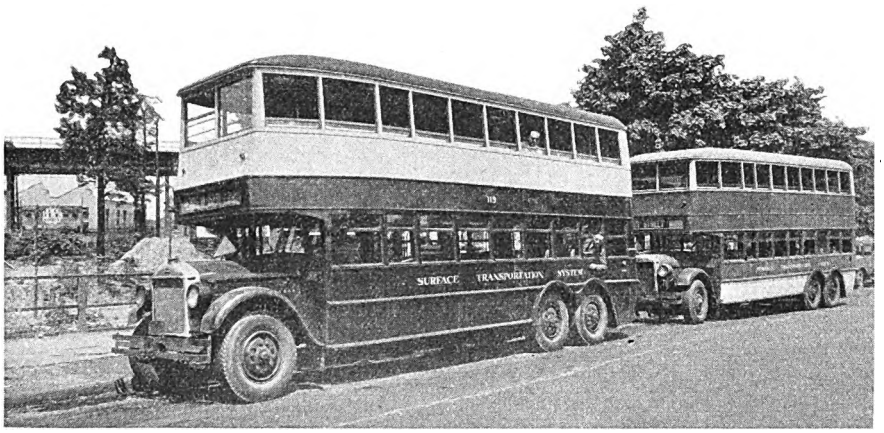
INDICATIVE of the value of properly co-ordinated street car and bus services is the experience of the Third Avenue Railway System, New York City. In the Borough of the Bronx, this company through its subsidiary, the Surface Transportation Corporation, in operating twelve extension and feeder bus routes covering approximately 60 miles. In Westchester County, the system includes two local and seven inter-urban routes, ranging in one-way mileage from 1.34 to 12, the total being slightly more than 58 miles. In this latter group five lines have replaced previous street car operations. Notwithstanding the fact that the bus systems have been installed in territories already well served by the street car lines of the Third Avenue Railway and the fact that receipts from bus operations now amount to approximately $6,000 a day, gross revenue from street car operations in both the Bronx and Westchester County have shown substantial increases.

For the system as a whole, due to traffic losses in Manhattan, the street car revenue for the year ending June 30, 1930, was 3.3 per cent below the preceding year.

Digitized by Google

REVENUES *of Third Avenue Railway*

in New York City



Double-deck buses seating 56 passengers are used on the two Concourse routes

Bus revenue for the system as a whole increased 11.2 per cent. The increase in net revenue from bus operations more than offset the decrease in net from rail operations.

Franchises covering the twelve routes in the Bronx were obtained from the City of New York under date of Aug. 4, 1927. The term of the original grant is for five years, with the right to renew for an additional five years resting with the company. The basis on which the franchises were secured was the 5-cent fare, although two routes were permitted two zones of 5 cents each, and two more routes were permitted three zones of 5 cents each. Two lines were put into operation during the latter part of 1927 and the system was completed during the following year. With these services in effect in the Bronx, the threatened invasion of the Third Avenue Railway Company's territory by independent bus operations disappeared.

Previous to 1927 the bus operations of the Third Avenue Railway were confined to scattered lines in Westchester County. Here again, independent bus operations threatened local and interurban street car lines. Therefore, under its subsidiaries operating in this territory, the company turned its efforts to the securing of a unified and co-ordinated bus system which would adequately serve the twenty municipalities in this area and protect the investment previously made.

After a long process of education both of the company and the communities served, fair and reasonable conditions of operation were obtained. Franchise agreements with these various municipalities and the agreements for the substitution of buses, where desirable, have now been concluded. For the most part, buses in Westchester County are operating on street car franchises by consent to substitute buses for cars. The street car franchises have in most cases about 70 years

to run. The consent for the substitution of buses provides for a minimum fare of 10 cents, with the right to reinstall tracks and car operations after ten years if such reinstallation seems desirable. This factor of the franchises is believed to warrant the sacrifices and expenditures necessary to develop a more extensive system. In fact, further substitution of buses for cars is under consideration in the southern part of Westchester County, in Mount Vernon, New Rochelle and the Pelhams.

On all lines the Third Avenue Railway System operates 177 buses, of which 133 are used in the Bronx and 44 in Westchester. New vehicles, consisting of Safeway six-wheel, A.C.F. and Versare gas-electric buses, were purchased for use on these systems, ranging in seating capacity from 56 to 23 passengers. On the two Concourse routes in the Bronx, 27 double-deck buses are used. In Westchester, six 41-passenger vehicles are operated on the White Plains-Tarrytown route, the remainder seating 29 passengers. The smaller, 23-passenger, buses are used generally in shuttle service in the Bronx. When these buses were purchased, the company financed 80 per cent of the cost with 5 per cent equipment certificates sold at par, which are being retired serially over a period of five years.

Garage facilities are centrally located for both the Bronx and Westchester systems. It was necessary to purchase land and construct a garage in White Plains for Westchester County. It is located within two blocks of Main Street, and on the Harlem division of the New York Central Railroad, with a siding on the property from which oil and gasoline can be delivered in tank car lots. In the Bronx, the company secured a central location, owned by a contractor, who built a modern garage to meet the railway's requirements on rental terms, which were very advantageous, as well as saving the outlay of a large amount of money. A building belonging to the Union Railway, a subsidiary, located on West Farms Road and 172nd Street, formerly a power plant, was reconstructed so as to make it particularly well adapted to the purposes of a general shop for the rebuilding of buses. Subsequent additions to this building house a machine shop, paint shop and storeroom. Buses from both systems are brought to this plant for general overhaul and repair.

Equipment Inspections and Overhaul

Maintenance practices include three schedule inspections and an overhaul. All are on a mileage basis as follows: At a minimum of 1,000 miles, buses are held in on a greasing inspection; at 2,000 miles the bus is given a general inspection, and at 20,000 miles a general engine inspection is made. At the end of approximately 1,000 miles buses are thoroughly inspected for grease, and lubricating materials are renewed. Heavy greases are used only in universal joints and wheel bearings. A 600-W type lubricant is used in the rear end and transmission, as well as in the grease cups. At the general, or 2,000-mile, inspection the body, engine, electrical equipment, treadle doors, seats and floors are thoroughly inspected. At the 20,000, or engine, inspection oil pans and cylinder heads are pulled, main and connecting rod bearings, pistons, rings and cylinder walls are checked and replacements are made if necessary. The general overhaul or repair is based on the condition of the bus at the various inspection periods. This averages approximately every 50,000 miles.

Bus operation and bus maintenance supervision are combined under one executive of the Third Avenue Railway System. A general superintendent heads both departments. This practice has been especially successful in co-ordinating operating and maintenance practices as well as instruction and discipline in both phases. Road supervisors and inspectors are schooled in both operating and maintenance methods and they, therefore, watch the effect of individual operation on the mechanical equipment. An example of the effect of this co-ordination is reflected in the greater tire mileages obtained over a short period. They have been increased from 12,000 to 19,000 miles. If an operator of a bus has abused equipment during his run, he is brought before a trial board consisting of the general superintendent, operating and maintenance officials, and given either instruction or discipline for his violation.

Curve construction for trolley bus showing one method of support

Successful Trolley Bus Operation Demands Suitable Overhead

The writer discusses the requirements of the service, which differ materially from street car work. The principles on which design of contact line and collectors is based are discussed

By

G. W. BOWER

Transportation Engineering Department
General Electric Company, Erie, Pa.

VARIOUS types of overhead contact and collector systems have been tried in the many years trolley buses have been in use. Probably the three systems that have been employed most widely are the over-running contact. the sliding contact, and the trolley-wheel.

With the over-running contact system the two contact wires, positive and negative, are so insulated and supported that a small carriage with grooved wheel can be towed along over the wires by a flexible cable which completes the electrical circuit between the trolley bus and the contact wire. This system has been used abroad to a limited extent, but in this country only for trial runs which were not successful.

Its chief advantage is that the touring range of the bus is limited only by the length of flexible cable that can be handled properly, and not by a pole of fixed length. Another supposed advantage is that two trolley buses can pass each other by an exchange of collectors.

Its disadvantages are the expense of constructing and maintaining a suitable overhead line and a collector carriage and the complication where routes cross each other or branch off. Also, it is unsuitable to combine with overhead systems used by a street railway.

In the sliding contact system, positive and negative contact wires are so insulated and supported that a collector consisting of two long shoes with horns, both flexibly mounted on a single pole supported by a trolley base, can slide beneath the wires. The collector is very simple and has no rotating parts. and the contact wires can be placed close enough together to be supported and insulated by a combined unit.

A disadvantage of this system is that complicated, special devices must be used in the overhead line where routes cross or branch off. The system does not readily lend itself to joint usage with existing street car systems.

The trolley wheel contact system has two contact wires and two separate trolley bases and poles, fitted with insulated swivel pole heads. The arrangement lends itself to joint usage with existing street railway overhead lines better than either of the previous types. Also much existing street railway standard line material may be used. Accordingly this system has, in this country, superseded all others.

Special Trolley Wheel Collectors Employed

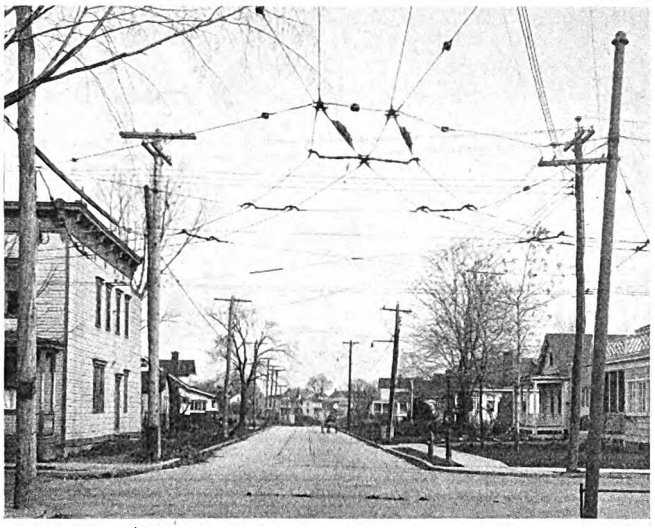
The limitations of the wheel collector should be known so that a large amount of standard street railway line material may be used. This, if properly installed, will prove very successful. There is nothing in the design of the collector that has not been used before, especially on street railways abroad where the trolley wire is located

Digitized by Google

alongside the right-of-way. The main changes are lengthening of the pole, adopting efficient bearings, and selecting operating angles to meet detouring requirements.

The latest installations use collectors with an 18-ft. pole. The base and pole head are so designed that the wheel will operate normally between the limits of 7 and 10 ft. above the bottom of the base. The limit of detouring range from under the contact wire within the above limits of height, on tangent overhead at normal speed should not exceed 10 to 12 ft. It is advisable to reduce speed when detouring to any great extent from under the contact wire on curves or under special overhead fittings.

The most recent collector bases and pole heads have roller bearings so as to respond readily to all the variations in the overhead system and the movements of the



Branch-off for trolley bus service. Insulators keep the two lines separate

bus on the street, and thereby keep a uniform wheel pressure against the wires. However, with the necessary weight of the 18-ft. pole and swivel pole head, this cannot be done if abrupt changes occur in the overhead system. Alignment of contact wire is, then, very important.

The pole head design is such that a line passing through the axis of the swivel bearing intersects at right angles the center line of the wheel bearing. The angle between the axis of the swivel bearing in the pole head and the center line of the pole is fixed, so there is only one position of the pole at which the axis of the swivel bearing will be perpendicular to the center line of the contact wire. This may be called the design position of the pole. If the pole is higher than the design position when the bus is directly under the contact wire, the swivel bearing gives the harp a slight leading caster effect, which is unstable. If the pole is lower than the design position when the bus is directly under the overhead, the swivel bearing gives the harp a slight trailing caster effect, which favors stability of the harp. If the bus diverges from under the overhead and the pole is above the design position, the harp and wheel are tipped in the direction to hook around the contact wire, which tends to prevent dewirements. If, however, the pole is below the design position and the bus diverges, the harp and wheel are tipped, tending to unhook the wheel groove from the contact wire.

Contact-wire height is very important in connection with the operation of a swivel-head collector. At points where the bus is likely to detour from under the contact wire, such as at designated curb stops, the wire height should be such as to maintain the pole at the middle point of its operating range. Care should also be taken in building and maintaining the overhead system to have the sides of the contact wire ears and splicing sleeves as nearly vertical as practicable to minimize the liability of the wheel flange fouling with the ear boss when the bus is detouring and the trolley wheel happens to be tilted.

The collector pole head was designed to permit the wheel to follow the varying positions of the contact wire with the least possible resistance and to give a certain amount of stability in backing. The only means by which the necessary force is obtained for moving the pole head under the wire is through the trolley pole, which is never in direct alignment but is always pulling the wheel along at some angle to its direction of travel. When the trolley bus detours from under the contact wire, the wheel and pole head must travel faster than the bus because of the increasing angularity between the pole and the contact wires. This calls for an additional force on the side of the wheel. It is, therefore, essential to reduce as far as possible the horizontal angularity of the pole to the contact wire, which becomes maximum because of side displacement of the wire when the collector approaches a support. This side displacement, which is caused by the side pull of the collector, will be reduced if a high tension is maintained in the contact wires.

The swivel-type harp is at certain speeds subject to "shimmying" as are the front wheels of an automobile when out of adjustment. Just as a rough road aggravates the shimmying of automobile wheels, a rough overhead may start the trolley wheel shimmying. With round wire, care should be used when installing the ears to see that they are well formed around the wire and also that the splicing sleeves are installed with their sides vertical so as not to aggrevate this tendency when the wheel passes such obstructions.

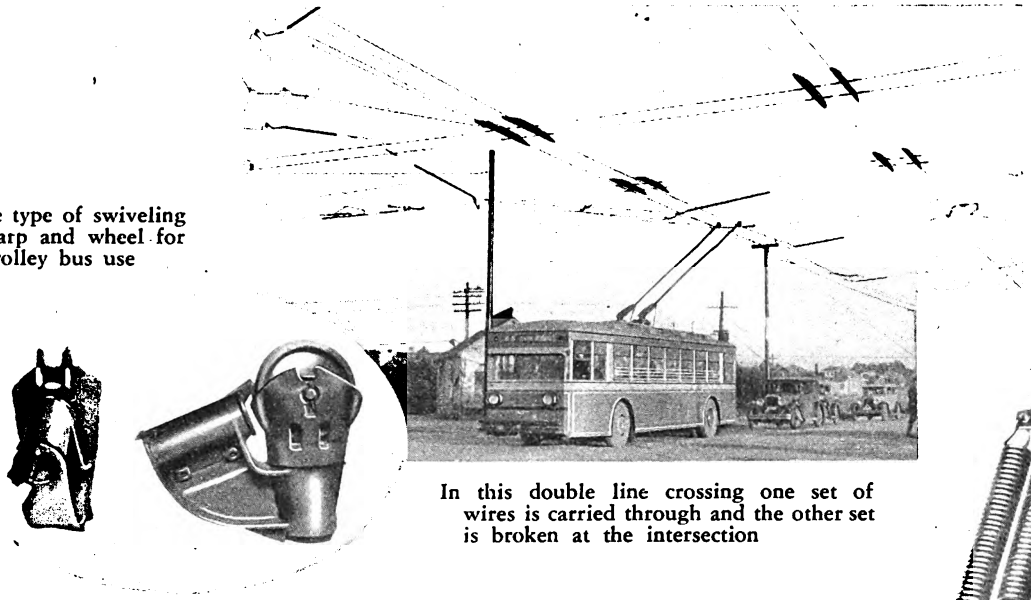
Both Single and Double Lines Used

In general, the overhead construction for trolley buses may be classified as a single line or a double line. A single line has two wires, positive and negative, corresponding to a single track street railway. Buses may or may not operate in both directions under it. A double line has four wires, corresponding to a double-track street railway.

Some portion or all of either the single or double lines may make joint use of the positive trolley wire of an existing street railway. When trolley buses and street cars make joint use of the same positive contact wire, such use prevents the detouring of the bus around a street car without the removal of the street car collector. The location of the street car overhead positive wire may be such that the bus touring radius is not sufficient to reach the curb. It also may be undesirable to make joint use of the street car overhead positive trolley wire on account of complications involved in the overhead construction, as sometimes a large number of special fittings are required. For a successful solution of each case a detailed study must be given to the various problems involved.

In erecting an overhead contact system for trolley-bus operation the methods used are the same as for direct suspension construction for street railways, with contact

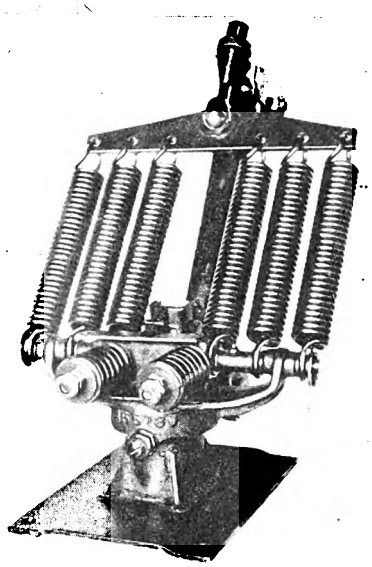
Digitized by Google



One type of swiveling harp and wheel for trolley bus use

In this double line crossing one set of wires is carried through and the other set is broken at the intersection

Swiveling trolley bases of this type are widely used on trolley buses



wires suspended at spans or brackets only. The pole spacing should not exceed 100 ft. and preferably should be less where special overhead fittings occur.

With cross span construction a second cross span across the street from pole to pole may be necessary to keep the contact wires supporting ears in a vertical position, if the cross span wire is heavily loaded with other wires and special overhead devices. The upper span is then given all the sag and carries the complete load. The lower cross span is largely used for holding the suspensions and special devices in proper position.

Contact Wire Location Depends on Service

If the service demands only a single line with bus traffic in both directions, the contact wires should be placed over the middle of the street. If the street is wider than 30 ft. it will be necessary, with the present design of collector, to displace the contact wires to the side of the street at points where scheduled curb stops are to be made.

So that the bus operator need not remove his collector from the contact wires when passing another bus moving in the opposite direction at scheduled meeting points, overhead turnouts may be installed. Since the collectors are the only parts that take the turnout, its length may be much shorter than for street car track turnouts. For a trolley bus overhead turnout, special frogs and crossings are required. The frogs should be of the one-way operating type so that a bus moving in either direction will always keep its respective contact wires at passing points.

If the service demands double overhead the center line of each pair of wires should be approximately 12 ft. from the curb line. When the contact wires are so located, the bus can pass parked vehicles at the curb and also can make curb stops without going beyond the operating range.

For either single or double overhead, a loop for turning the buses is desirable, although they may be turned on a wye in the overhead system where space will not permit construction of a loop. The wye requires special frogs and crossings, which call for more maintenance than standard fittings used on loops. Where wyes are used, the trolley wires should be installed at normal height and good tension maintained.

When positive and negative feeders are required, it is best for safety reasons to keep the negative feeder on the opposite pole line from the positive. The negative feeder is always insulated the same as the positive. Taps from the feeder to the contact wires should be carried by a cross span located above the supporting span, with the taps dropped down to the feeder ears attached to the contact wires. A feeder ear with a suspension boss should be used. It is best for insulation and for safety to make the negative and positive feeder taps at adjacent spans rather than at the same span.

Generally speaking, the principles used for sectionalizing street railway lines apply to trolley bus lines. It may be desirable to install section insulators, normally shunted, in the negative trolley wire, permitting disconnection of the negative wire for the safety of linemen in working on certain sections.

Practically all existing trolley bus installations in this country make use of standard street railway suspensions with either a porcelain or wood strain insulator between the positive and negative contact wires. Since the trolley bus collector consists of two separate units which for mechanical and electrical clearance require approximately 24 in. between centers, the contact wires are spaced the same distance on tangents and in some instances slightly greater on curves. Later installations use the same spacing for both tangent and curves.

The nominal spacing of 24 in. for the trolley wires is too great for an economical combined unit with two insulated suspensions and double insulation. The practice of installing a strain insulator in the span between the insulated hangers no doubt had its origin in a similar practice of reinforcing suspension insulation on regular street railway work. It seems quite probable that on new work satisfactory insulation between positive and negative can be obtained at a lower cost by using a better quality of insulation than is regularly used in street railway suspensions. On account of the possibility, however, of the cross span wire becoming energized because of a dewired wheel, a strain insulator should be placed in the cross span next to the pole.

Digitized by Google

On curved sections straight-line suspensions should be avoided when tilting of the ears cannot be prevented. The number of curve suspensions should be such that at no pull-off point will the deflection angle be more than 12 deg. All contact wire ears should be formed at such points to correspond to the arc of the curve. No curve in the overhead should have a smaller radius than the turning radius of the bus.

On account of the angularity which a swivel harp gives the wheel when proper trolley wire heights are not maintained, it is very important that all devices in the overhead system give the maximum wheel clearance possible. Existing trolley bus overhead systems as a rule use round wire and clinch ears of various lengths. Of late years, in order to obtain long life, the lip thickness has been increased. Special care should be taken when installing them to peen the lips close to the wire. Grooved contact wire with clinch ears gives far better clearance and eliminates many of the ear troubles experienced with round wire. It should be given consideration.

In selecting splicing sleeves for trolley-bus service, wheel clearance is the most essential point. It is best to use a sleeve with a small height so as to reduce the turning tendency as much as possible.

Special Frogs Are Required

Since the wheel of a trolley bus collector is free to turn about its swivel bearing, it must at all times be guided in the direction in which it should travel. For this reason standard street railway contact wire frogs should be used only when the travel is from the double end to the single end. In order for the wheel to pass through a frog in the other direction, the path for the wheel tread must be continuous. This is accomplished by having frogs with a movable tongue for the tread of the wheel to follow, of which there are three types, operated by spring, mechanically, and electro-magnetically.

The spring type frog is similar to any standard street railway overhead frog except that it has a tongue which completes the path for the trolley wheel tread from one end to the other. This is so hinged that, when a wheel passes on the runway not connected with the movable tongue, its flange may crowd the tongue to the side and allow the wheel to pass through. When a wheel passes in the opposite direction, it always follows the runways connected with the movable tongue. In earlier designs the movable tongue consisted of a flat spring, but as it deteriorated rapidly later designs have a hinged tongue held in position by a coil spring.

The spring frog is used where the bus operator need not select the route, as at the junction point of a loop and a single line overhead system, junction points in a wye and on single-line turnouts.

The mechanical type frog has a movable tongue connected by an insulated rod to a treadle in the other trolley wire. When the trolley wheel passes the treadle, it operates the movable tongue in the frog for guiding the wheel passing through it in the same direction as the trolley wire with the treadle. The mechanical frog is used only where the trolley bus overhead branches off from a street car system.

The electro-magnetic frog has two solenoids to move the tongue. For its operation special devices must be installed in the overhead adjacent to the frogs that will under certain conditions allow current to pass through the proper solenoid to move the tongue. The electro-magnetic frog is used where route selection to be made by the bus operator, as where lines branch off.

Pennsylvania Railroad

First unit in expansion program placed in service is suburban terminal in heart of the city and a connecting underground line

RAPID progress is being made in the reconstruction of the Pennsylvania Railroad's tracks and terminals in Philadelphia, which forms an integral part of the major electrification project which is being carried out by the railroad. The principal changes in the Philadelphia district are centered in the construction of a new passenger station for through and suburban trains at 30th and Arch Streets, a new underground suburban terminal at Sixteenth Street and Pennsylvania Boulevard (formerly Filbert Street), and the abandonment of the steam terminal at Broad and Market Streets and the West Philadelphia station at 32nd and Market Streets.

Progress in the work is being watched with interest, since it involves maintaining a very heavy train service through the territory while the new construction is going on. The transfer of train service from the old to the new facilities is being carried out in a series of steps planned to produce as little interference as possible. It is expected that the improvements will be in full use late in 1933.

The first unit in the plan, the suburban terminal, the connecting tracks and the portion of the 30th Street station reserved for suburban trains, was put in service on Sept. 28. Temporarily, a few suburban train movements are being made into the old Broad Street station, and steam trains terminating in Philadelphia are being operated to and from there. Ultimately, all of the 325 daily suburban electric trains will use the new stations. As soon as the construction of the through terminal at 30th Street has progressed far enough, movements to the old Broad Street Station will cease and the viaduct adjacent to Market Street will be torn down. The land will be used in part for widening Pennsylvania Boulevard and in part for construction of office buildings facing on Market Street.

The main terminal station at 30th Street will have two track levels, the lower one for through trains hauled by locomotives and the upper one for suburban trains of multiple-unit cars, with a passenger concourse on the level between the two. The sixteen tracks for the through trains on the lower level will run north and south, in general paralleling the Schuylkill River. Facilities will be provided so that through trains between New York and the West can enter and leave the station by means of loop tracks without reversing direction. Trains between New York and Washington will pass directly through the station. The six suburban tracks run east and west above the passenger concourse at the north end of the station. The arrangement will provide for transfer of passengers between the through trains and the suburban trains reaching the heart of Philadelphia.

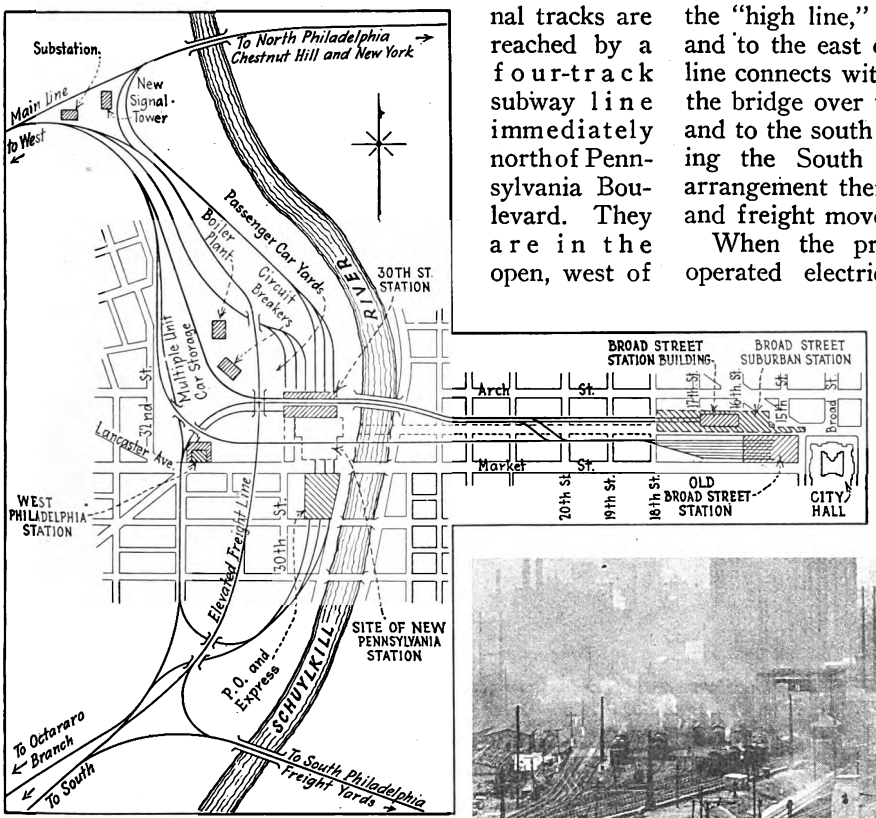
The Broad Street suburban terminal occupies a position immediately to the north and west of the present Broad Street station. It is 1,000 ft. long and 200 ft. wide. The passenger concourse is beneath the ground level, being reached by convenient stairways and passage-

Digitized by Google

Opens New Facilities in Philadelphia

ways connecting with the adjacent streets, the Broad Street station, the Broad Street subway station and the new Broad Street Station Building, which has been erected above the suburban terminal at the northwest corner of Sixteenth Street and Pennsylvania Boulevard, extending westward to Seventeenth Street. The tracks are immediately beneath the passenger concourse. At present, seven have been installed, and the number will be increased to twelve as the project develops.

The terminal tracks are reached by a four-track subway line immediately north of Pennsylvania Boulevard. They are in the open, west of



The principal improvements of the Pennsylvania Railroad electrification centering in Philadelphia include new through and suburban stations and removal of the masonry viaduct adjacent to Market Street

Twentieth Street, and, after climbing a grade, cross the Schuylkill River on a masonry bridge, immediately west of which is the 30th Street station.

A temporary connection has been made in the vicinity of 21st Street so that through trains can be operated over the new line into the Broad Street station. This will permit the present line between that point and the West Philadelphia station to be abandoned, so that construction of the lower level and the station building at 30th Street can be carried out. There will be sixteen tracks on the ground level when the project is completed, and the station building will extend south to Market Street. Immediately south of the station will be a new building for handling mail and express. To the north of the suburban line and west of the through tracks there will be a storage yard for passenger cars. This construction is now in progress. Storage space for multiple-unit suburban cars will be to the west near the present line between New York and the south.

All track connections are made through a system of elevated and depressed tracks, so that there are no grade crossings. This facilitates train movements and eliminates interlocking plants.

Freight movements through the district will continue to be made over an elevated structure, known locally as the "high line," located to the west of the new station and to the east of the West Philadelphia station. This line connects with the main line tracks in the vicinity of the bridge over the Schuylkill River in Fairmount Park and to the south near the connection with the line reaching the South Philadelphia freight yards. By this arrangement there is no interference between passenger and freight movements in the entire terminal area.

When the project is completed all trains will be operated electrically from the single-phase, 25-cycle trolley at a normal potential of 11,000 volts. Power for the electrification is received from the Philadelphia Electric Company at the Lamokin Street substation, Chester, and distributed at 132,000 volts, except for the terminal area and the line to Paoli, which are supplied by the older part of the system at 44,000 volts. Stepdown transformer stations, unattended and operated usually from adjacent signal towers, are located 5 to 10 miles apart. The trolley feeders in the vicinity of the new 30th Street station are controlled by high-speed, air-break circuit breakers located on a steel structure adjacent to the station. Alongside it is a boiler plant for supplying steam for heating the station and cars stored in the yard.

Many lax and inefficient methods of operation have been handed down by old men acting as instructors for recruits

Observations on Methods of Training Platform Men

By a

Veteran Electric Railway Official

Years of experience have proved that expert follow-up instruction of trainmen in the routine operation of their cars will result in worth-while economies. Co-operative remuneration based on savings in accidents and power costs encourages trainmen to improve their performance

IF YOU were to ask your superintendent of transportation who were the best operators your company had, he would almost certainly name those having the least number of accidents charged against their records. That would have been the way our superintendent would have answered you up to the time we began to look for economies in operation other than those shown in the amount spent on accident claims. These men were so classed because they were "very careful men." They were careful because they never took a chance, and as a result had excellent accident records. However, upon looking into other features of operation which were responsible for a large expenditure of money, it was found that these careful men were usually expensive operators in other ways involving the proper handling of the electrical apparatus on the car.

These men were often used as instructors for new recruits, with the result that many lax and inefficient methods of handling a car controller have been handed down from one man to another since the beginning of electric transportation. It is my belief that, although many companies have schools of instruction for beginners with large rooms filled with elaborate displays of various devices used on the cars, as well as diagrams of wiring, etc., the new recruit, whether having had this instruction or not, receives his strongest impression from observing how the man on the front platform performs his duty. I wish to emphasize the fact that better results will be obtained from practical instruction on the front platform in every-day service than from any other method now in use, provided the instructor is an expert in up-to-date operating ideas.

If worth-while economies of operation are to be effected, the first step to be taken must be the adoption of some plan to arouse the interest of the operators in their duties. If you are successful in interesting your men and holding them to their work with little effort, it will

Digitized by Google

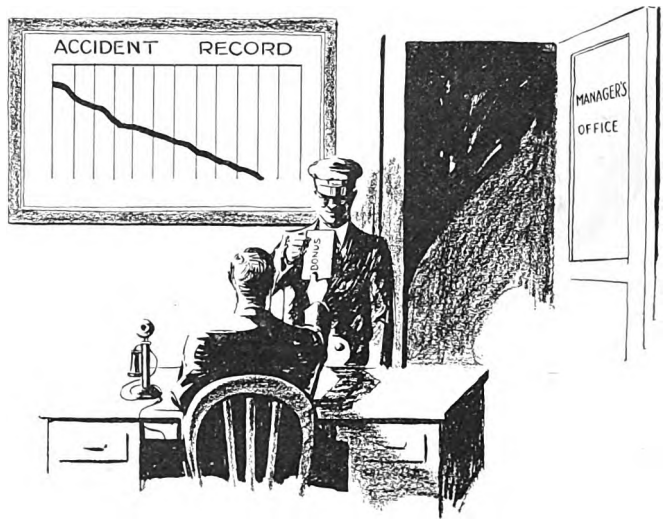
mean not only an improved quality of service, but will result in economies such as lower power consumption, lower maintenance costs of equipment and in a considerable reduction in claims for accidents. It is my belief that the means for arousing interest should not only be practical of application but profitable to the men as well as to the company. Bonuses based on attention to duty, efficient operation and safety have solved the problem on our property, and I feel sure can do so on many others.

Bonus Plan Arouses Interest In Accident Prevention

Payment of an accident bonus was one of the first steps we took in our program of the co-operative method of remuneration for platform men. About ten years ago we made an exhaustive survey of our claim department in endeavoring to reduce the number of accidents, which were entirely too numerous and costly. We found the department was doing everything possible in a legal, as well as persuave, manner to cut the cost of all claims. Officials were talking to the men from time to time in meetings. We had called upon the safety director of the city to assist by explaining what his department was doing to teach pupils in schools as well as the general public to practice safety at all times. This helped some, but it did not always last long. We had a safety banner which was held by the carhouse having the least number of accidents for a certain period, and this honor was keenly contested for throughout the property. We had an honor roll of men who had been free from accidents for a year, and at a banquet, held at the club room, a bronze medal was presented to each member of the roll by the general manager. All of the various schemes tried helped for a time and we spent a lot of money in an effort to cut out this cancerous growth which seemed to live upon that part of our resources intended for dividends. The money spent did not buy any shoes for the operators' children nor materially reduce the number of accidents.

Taking an average of the money paid out in claims for the previous five years, together with the money spent in putting on the foregoing safety campaign, we found it amounted to approximately $7,000 per year. This money all went outside of our organization to the benefit of people in whom we had no interest whatever. It occurred to me that it might be worth while to figure out some manner in which this money could be used to better advantage to the company than in the payment of claims. It was decided to offer the operators of our cars, all of which were one-man, 50 per cent of all money saved by the elimination of accidents. This would be paid in the form of a bonus of $30 for each man having not only a clean record on accidents for which he might be responsible, but from other violations of any nature such as failure to show up for his runs, discourtesy, missing fares and the like.

Payment of this bonus was to be made just prior to the Christmas season, and when the announcement putting it in force was made, great stress was made of the benefits to be derived from the receipt of this additional money at such an auspicious time. The men were enthusiastic over the proposition about like everything else we had tried in the past, so we were not at all alarmed over the fact that this bonus might amount to more than 50 per cent of all money saved by the elimination of accidents. But unlooked for results were obtained at once. This bonus has now been in operation for more than ten years, with the result that accidents of all kinds for which our men might be responsible have been eliminated to such an extent that the amount paid out in claims, together with the bonus, does not amount to



It is a good plan to divide with the operators the savings resulting from reduction in the number of accidents

any more than one-half the amount previously paid out for claims alone, and most of it goes to the operatives, where it belongs.

Another bonus was decided on to straighten out the kinks in our employment department. Any operator having a clear record for 30 days, no accidents or violations of any nature, was entitled to one day off the following month, with pay allowed. The day was to be of his own choosing and subject to such arrangements as the supervisor could make for a substitute to take his place. As a result of this bonus, minor violations passed into the discard to such an extent that we reduced our extra list to the absolute minimum. A large number of our men have been receiving not only a yearly bonus but each monthly one, which figures to approximately $90 per year for prize money, well spent and gratefully received.

As I have stated, to be efficient, an operator must not only be able to cut down losses from preventable accidents but those resulting from the excessive and wasteful use of power by improperly operating all electrical appliances installed on the modern electric car. Training to this end must begin with the recruit. Regardless of any school instruction, a new trainman must learn his operating practices and form his habits on the platform of a car under the guidance of someone with experience. I am a firm believer in expert platform instruction by competent men who do nothing else but supervise the actions and duties of the operators. These supervisors must not only be able to give them the theory of proper control of the car, but must be able to show the better way by demonstration under actual conditions. When I mention the proper handling of the controller I am referring not only to the speed with which the operator notches it, but to the fact that he too often runs on resistance points or throws the controller on and off too frequently, not being able to judge conditions and speed, and keeps power on for too long a time when approaching a stop, eliminating the amount of coasting to be obtained in any length of run with a resultant saving in power. Mechanical and electrical devices have been perfected to control the acceleration of motors, and

Digitized by Google

some companies have adopted these rather than find a way to assure proper performance by the man in charge of the car, but I prefer to have our men in entire charge of this feature and hold them absolutely responsible for the proper use of not only the controller but the brake valve as well.

Efforts To Save Power Should Include Auxiliary Uses As Well As Motors

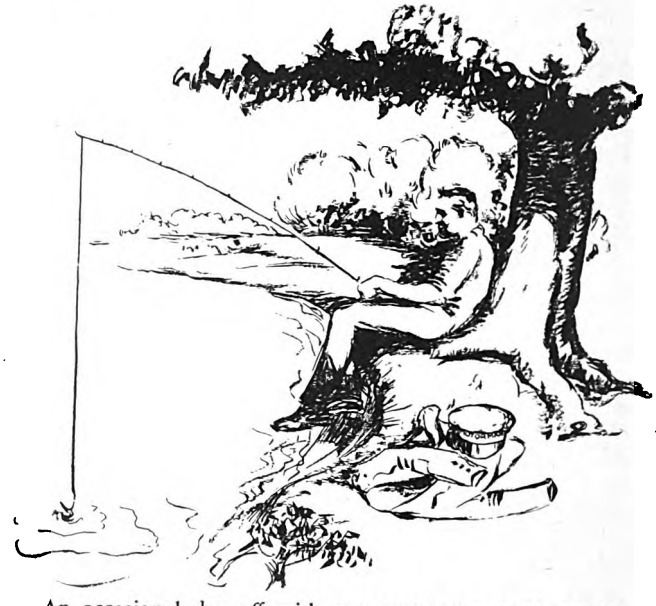
The use of power-saving meters was advocated a number of years ago to register the amount of current passing through the motors. They were used in an effort to cut down the amount of power consumed and to enable the mechanical department to inspect or overhaul equipment on a specified kilowatt-hour basis. The use of these meters is an excellent method of checking current consumption of motors, but that is only a part of the total amount consumed by the apparatus on a street car. When one considers the amount of work it is necessary for the air compressors to perform with the addition of air-operated door mechanism to the previously installed braking apparatus, it is time to give the matter considerable thought. In my opinion, the meter should be so connected that it will include the compressor and the lighting circuits as well as the motors, because there is a great waste of current in these two circuits in proportion to the waste in the motor circuit. If you want to economize, why not get all there is to save instead of only a portion? This would not necessarily destroy the feature of inspection measured by current consumption, as a new standard could be established for the various types of equipment. I am aware of one company which has had meters installed in the motor circuit only for approximately three years and has obtained a saving by their use of from 10 to 15 per cent. This is an attractive sum considering the amount of the power bill, but is not as much as could be obtained should the meters be connected to include the lighting and compressor circuits. There is no means of ascertaining the power losses incurred by improper operation of the brake valve unless meters are installed to cover all electrical units. I am confident that with an improved method of operating the controller and brake valve, additional savings in power of approximately 10 per cent in the motor circuit and from 5 to 7 per cent in the compressor and lighting circuits could be made on this property.

On our property we do not use meters except to check current consumption on our various types of cars under normal service conditions and for special tests we may wish to make. When we took up this matter of power saving we had a separate meter installed to register the amount of power used by the shops so as to give us a reasonable figure for car operation by subtracting the shop current from our total monthly bill. We figured out our monthly power consumption on a kilowatt-hour per car-mile basis for a typical month or two to obtain an average with which to compare. We also made a blind test on various runs to check with the average kilowatt-hours, obtained from the monthly bill and found them near enough to have something to shoot at.

To be even more certain of our figures, we made the test for saving on the same runs on corresponding days as for the blind test, and in each case the meter was connected so as to include the motor, compressor and lighting circuits. In view of the fact that it was not convenient to give sufficient training in our new method of operating the controller and brake valves before the tests were made, we were surprised to find that there was a difference of 25 per cent on one run and 22 per cent on two others.

Efficient Operation Depends Upon Personal Interest

Our power cost per year has averaged $130,000 for the past two years. It can readily be seen that the amount we have been paying to the power company should have been used to better advantage. It is a lot of money and one wonders why not only our company but many others have allowed it to be so carelessly expended. We all believe we are giving the proper and necessary training to our employees to obtain the minimum amount of current consumption necessary for correct and efficient operation, but we are not. I take the stand that regardless of the kind of training the operator of an electric car receives, his efficient application of the knowledge obtained depends upon the personal interest he takes in his work.



An occasional day off with pay encourages operators to keep their records clear of accidents or violations

This has been demonstrated to us by the use of the two bonuses mentioned previously. If there are any hopes of saving power either by the use of meters or automatic devices or methods dependent upon the human element for correct handling of the apparatus, it will be necessary to interest the man responsible. Let us take an average of $25,000 which has been going to the power company for several years and see how it could be advantageously distributed. We could afford to give 50 per cent of this saving to the platform men as a bonus, provided they saved it by better and more efficient operation of the equipment, and the remaining 50 per cent could be used for any other purpose we might select such as the purchase of new equipment and the like. The strange thing is that a company would not have to spend any large amount of money to obtain this saving unless it desired to purchase meters, in which case the cost of them could be taken out of your share of it.

Many economies such as those I have mentioned can be realized through the efforts of the trainman and through no one else. School the recruit from the very beginning of his service in the proper practices of car operation, follow him up with expert supervision in his every-day duties and gain his interest by sharing the profits he is earning. The results of these efforts will mean more profits to your company.

New MAINTENANCE CONTEST

Quarterly prizes and individual cash prize to be awarded on substantially the same basis as in previous contests. New plan for company award to be announced later

ELECTRIC RAILWAY JOURNAL plans to continue, during the coming year, the Maintenance Contest so successfully conducted during the past several years in co-operation with the American Electric Railway Engineering Association. The conditions and rules of the new contest are substantially the same as those of the last previous contest, except in so far as the company award is concerned. It has been decided to broaden the scope of this feature of the contest, and new rules are being formulated. These will be announced later.

The committee of judges for the contest will consist of W. W. Wysor, chief engineer United Railways & Electric Company of Baltimore; R. H. Dalgleish, chief engineer Capital Traction Company, Washington, D. C.; W. J. Quinn, electrical engineer Third Avenue Railway, New York, N. Y.; A. W. Baker, engineering secretary A.E.R.A.; and J. A. Miller, Jr., editor ELECTRIC RAILWAY JOURNAL.

Rules

1 The contest will be judged and the prizes awarded by a committee of the American Railway Engineering Association. All decisions of the judges in interpreting the conditions of the contest and in making awards will be final.

2 Quarterly prizes of $25 will be given for the best items submitted in each of four departments. The best maintenance idea submitted during the entire contest period will receive an award of $100. A minimum of $5 will be paid for each item published.

3 Articles may describe any maintenance practice or device used by any department of a railway, such as the maintenance of rolling stock, buses, shop equipment, or methods and equipment for overhead line repairs, power distribution and power generation devices, signal work, track and way maintenance, etc. The judges will determine the classification under the following divisions: (1) rolling stock and shops; (2) way and structures; (3) electrical and line; (4) buses and garage.

4 Articles submitted for these prizes should be *preferably* 100 to 200 words in length and should be accompanied by at least *one* illustration. Brevity consistent with a proper presentation of necessary information will be given weight in judging articles. In no event should they be longer than 400 words. Write on one side of the paper only. Have the article typed if possible, but manuscript written long hand will be accepted. Whenever possible include data on cost savings effected.

5 In rating the various articles the committee will consider the primary value of the method or device as of highest importance. The committee will also consider its practicability, the advantages and economies that are set forth and the clearness and completeness with which the idea is presented.

6 Any employee or official of an operating electric railway or bus company may compete for the prizes.

7 Each contestant may submit any number of items he desires, each of which will be judged separately. An individual may win several of the prizes. Manuscript must be marked "Maintenance Competition." Any number of items may be sent in the same envelope.

8 The author does not necessarily have to be the originator of the idea, but it must be adopted and be in use on the property with which he is connected. The idea submitted may have originated on another property or may have been furnished by a manufacturer. No device or method, a description of which, to the knowledge of the contestant or the judges, has been previously published, will be eligible for this competition. More than one article covering the same device or method will not be accepted.

Additional copies of these rules and full details of the contest may be obtained upon application to ELECTRIC RAILWAY JOURNAL *or the American Electric Railway Association.*

9 Where the management of a railway has a practice of requiring approval of articles sent out for publication, such approval *must accompany* the manuscript. If written approval does not accompany the manuscript it will be assumed that such approval is *unnecessary*.

10 An article may be submitted by several persons or by a department, and need not be written by the person in whose name it is submitted. The prize will be awarded to the individual or department whose name appears on the manuscript, and may be distributed among the winners on any basis determined upon by them. Should there be a tie for any prize the full amount will be awarded for each of the articles involved in the tie.

11 All articles should be addressed to the Contest Editor of ELECTRIC RAILWAY JOURNAL, Tenth Avenue at 36th Street, New York City. Items to be eligible for the first period prizes must bear a postmark not later than Jan. 31, 1931; for the second group not later than April 30, 1931; for the third group not later than July 31, 1931.

12 The announcement of winners of departmental prizes will be made in the issue of ELECTRIC RAILWAY JOURNAL in the month following the closing date for each group of departmental prizes.

13 Material submitted in the contest may be published at any time.

14 ELECTRIC RAILWAY JOURNAL shall have exclusive right to the publication of all material entered in this contest. All articles submitted will become the property of ELECTRIC RAILWAY JOURNAL and no manuscripts will be returned.

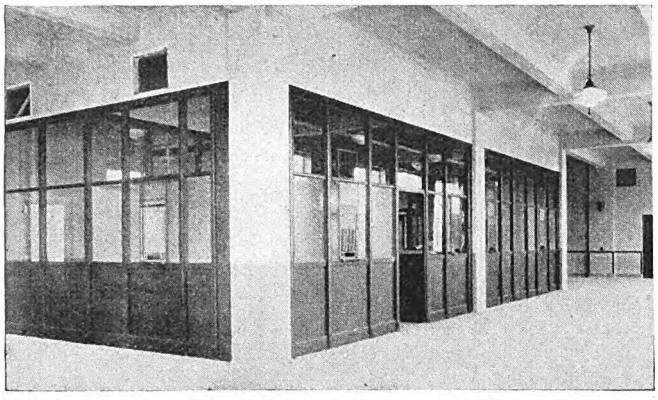
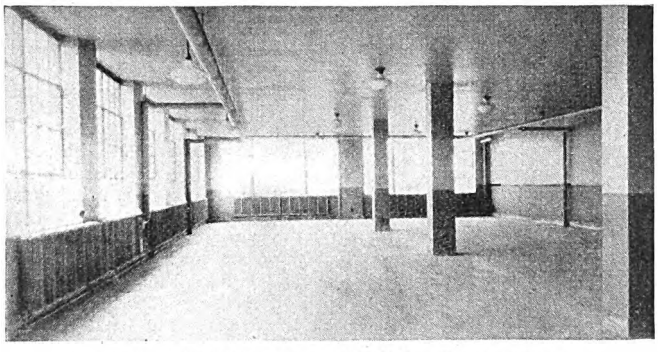
Ornamental brick construction gives attractive appearance to the two-story front of new Wyoming carhouse of the Department of Street Railways, Detroit

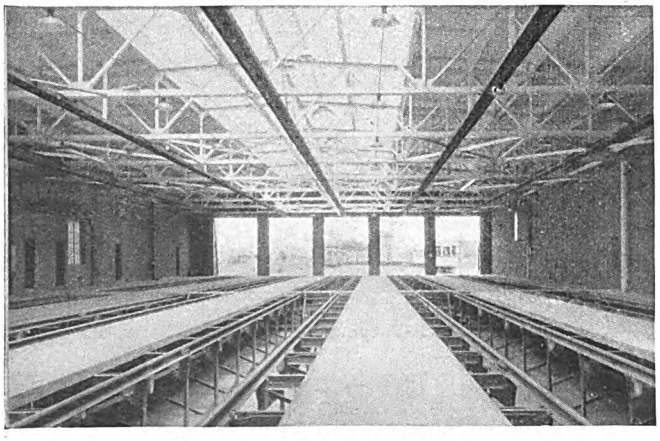
New Carhouse



A spacious lobby surrounds offices of station master and cashier



Large quarters are provided for the comfort of car crews



Open-type repair pits facilitate car inspection

ADDITIONAL storage and service facilities have recently been made available to the Department of Street Railways, Detroit, through the construction of a combined office building and carhouse. Carefully planned and well constructed, the building has many desirable features including excellent light, good ventilation and a pleasing appearance. It contains office quarters, a lobby, inspection pit room, workshop, car washroom, paint room, boiler room, dormitory and comfort facilities for repair men and car men.

The building is located on a large tract of land at Wyoming and Michigan Avenues in the city of Dearborn, a short distance from the Ford Motor Company plant. It is 222 ft. long and 176 ft. 8 in. wide. A two-story front faces Wyoming Avenue and extends to the rear for a depth of 36 ft. With the exception of the roof, which is of wooden construction, the entire building is of concrete, steel and masonry. Colonial face brick, laid in ornamental patterns, is used for the two-story portion of the building. This portion is also ornamented with door hoods, inset panels, pilaster caps and a heavy coping of stone.

The office quarters are on the first floor. They include the lobby, superintendents' and station masters' offices, cashiers' enclosures, a room for records and a lavatory for the office staff. The lobby is spacious and well lighted, and has a terrazzo floor in shades of buff and black. Its walls are lined to a height of 3 ft. 6 in. with a wainscot covered with imported ceramic tile in pastel shades of buff and green, bordered with black. The rest of the interior is plastered and finished with flat ivory tint.

The superintendents' and station masters' offices and cashiers' enclosures are floored with asbestos tile in a checker-board pattern, in maroon and black. The partitions are of steel, 10 ft. high, finished in imitation mahogany and are glazed with Florentine and polished plate glass. A steel staircase with terrazzo treads leads from the first floor lobby to the assembly room on the second floor. Adjoining the lobby is the record room fitted with

Digitized by Google

shelving and provided with ventilating ducts. The cashiers' enclosures are of wire mesh extending to the ceiling, and having sliding doors fitted with special locks. Illumination of the lobby and offices is obtained from ornamental hanging fixtures. Bronze-finish wall fixtures of the pocket type for indirect lighting give additional illumination in the lobby.

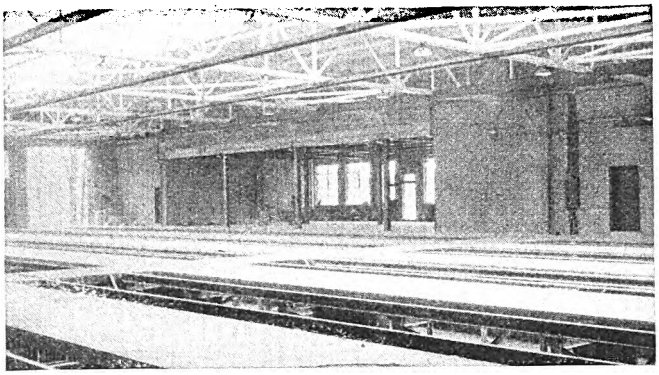
The entire second floor is given over to the convenience and comfort of car crews. It contains an assembly room, 34x79 ft., a locker room 34x79 ft., and a dormitory 34x38 ft. 6 in. A washroom is located near the lockers. It is equipped with shower bath, and is lighted and ventilated by a large skylight.

The pit room of the carhouse is 79 ft. wide and contains ten repair pits each 100 ft. long over which twenty cars or ten trains may be serviced at one time. Inasmuch as all track work on the premises is laid down for rotary

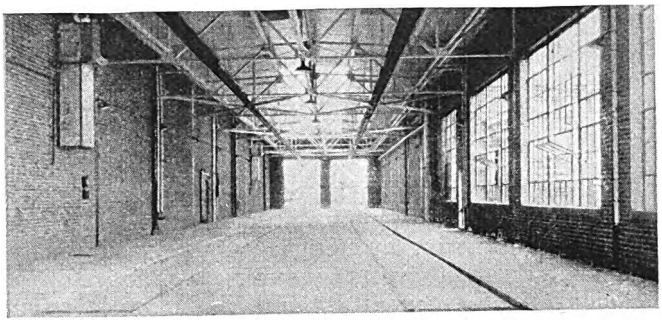
Built at Detroit

traffic, movement of the cars through the entire carhouse is accomplished with maximum efficiency and minimum loss of time. All repair pits are of the open type. Steel bents, light yet sturdy, support the tracks and the concrete walks. Beside the tracks, a 2-ft. open space between each rail and the edge of the walk adjoining, permits ready and convenient adjustment to running gear from both lower pit floor and walk. The space under the floor slabs is utilized for storage of spare parts and tools. It also accommodates the numerous radiators, which, in addition to the indirect heaters near the ceiling, comprise the heating facilities of the pit room. At one side of the pit room is the shop space, 36x68ft. Here the air compressor, forge, lathe, drill press and work bench are located. On the same side are also a washroom and lockers for the repairmen and an oil storage room.

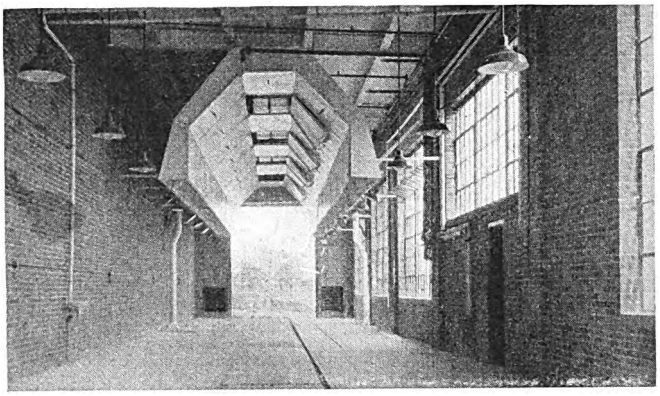
Over the repair pits, giving a maximum of light and ventilation, is a skylight 24 ft. wide and 180 ft. long,



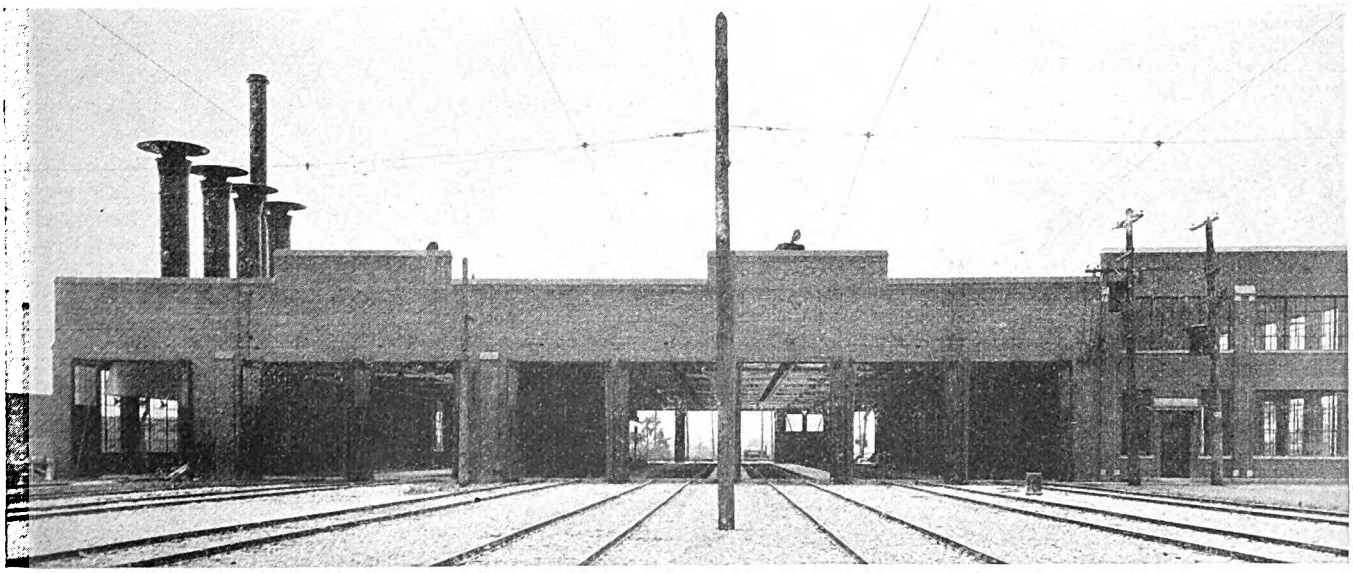
Workshop is conveniently located at one corner of pit room



Spacious washroom will accommodate eight cars at a time



Paint shop is equipped with an all-metal spray hood



Offices are on the Wyoming Avenue side at the right. Next are the inspection pits. At left are the shops

Digitized by Google

equipped with five ventilators, 48 in. in diameter, with cowls rotating on ball bearings. Adjoining the pit room is a wash rack with two tracks running its length. The facilities installed in this room will permit the cleaning and washing of eight cars at one time. Ample light and ventilation is obtained from a large skylight on the roof and steel sash in the side wall. Numerous floor drains, hot and cold-water outlets, and facilities for the installation of car-washing sprayers have been provided. A storage room for washers' supplies is also located here.

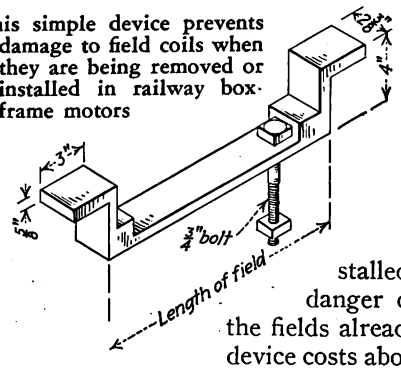
Next to the wash rack is the paint shop which is 22x120 ft. This shop is entirely fireproof, reinforced cement tile having been used in the roof construction. The all-metal spray hood for spray painting is 40 ft. wide and 61 ft. long. Two blowers at the side walls force a volume of air into trenches parallel to the track. This air is released through a longitudinal slot in the top of the trench, forming an air curtain along the object being sprayed. The spray residue carried upward by the air, is caught by the exhaust of a series of blowers connected to four ventilating stacks, 42 in. in diameter and 20 ft. high. A sprinkler system is also one of the features installed to eliminate fire hazard.

The entire building is heated by two steel tubular boilers equipped with automatic stokers. They are installed together with an auxiliary water heating boiler in a boiler room, 40x56 ft. under the easterly part of the building. In the boiler room are also located various pumps which complete the heating plant. These include duplex vacuum pumps, hot water circulating pumps and two automatic sump pumps. A large coal storage room and an ash room, in which is erected an electrically operated ash hoist, are included in the boiler room area.

Clamp for Installing Field Coils*

By R. Dumke
Foreman Mechanical Department Cleveland Railway

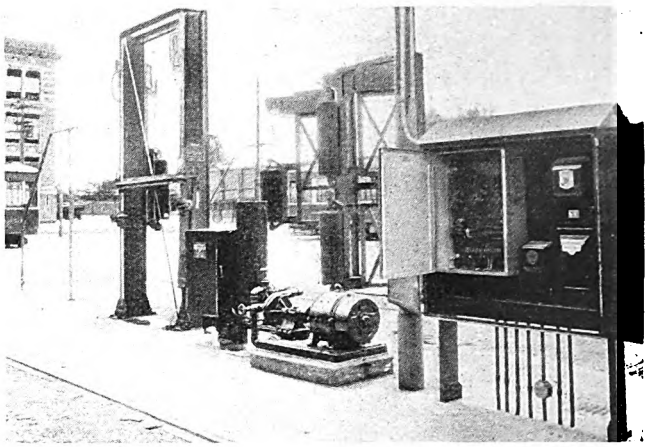
INSTALLATION of field coils in box-frame motors is facilitated by the use of the clamp illustrated, which was designed and constructed in the motor department of the Cleveland Railway. As may be seen in the illustration the device is very simple. By its means the adjacent fields can be held in place securely, while they can be shifted so as to allow the new field to be installed without any danger of injuring it or the fields already in place. The device costs about $5. It replaces the old method, in which it was necessary to remove the pole pieces in the adjacent fields in order to loosen them so that a defective field could be taken out and a new one installed. The adjacent fields had to be blocked or held in place, after which the old field was forced out and the new one forced into place. Frequently the new fields or the ones adjacent were damaged or shorted.



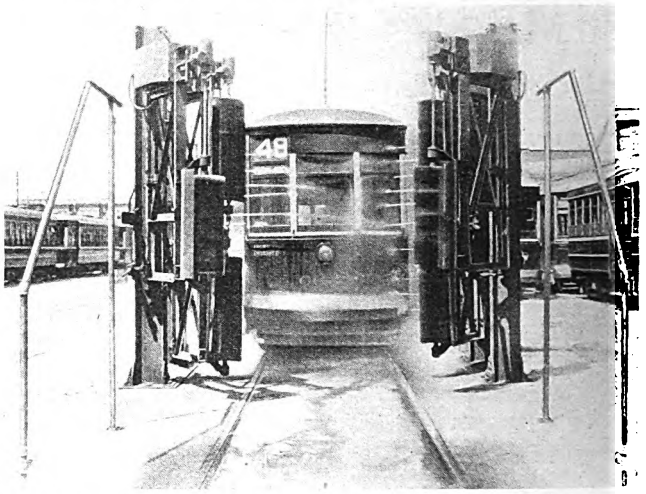
This simple device prevents damage to field coils when they are being removed or installed in railway box-frame motors

Submitted in Electric Railway Journal Prize Contest.

Car Washing Machines Make Large Savings in Philadelphia



Car washers of this type are installed at five principal carhouses in Philadelphia. As the cars pass through the machine they are wet with the sprays, then scrubbed by rotating brushes and finally rinsed by another spray



SOME time ago the Philadelphia Rapid Transit Company began experiments in the use of car washing machines for use on its surface lines. The original machine was quite similar to that developed some time ago by the Pittsburgh Railway. After adapting the machine to the requirements in Philadelphia, five were purchased from Leeds, Tozzer & Company, of New York. The new machine, as installed at the Luzerne carhouse, is shown in the illustration.

There are two steel uprights, one on each side of the track to which swinging arms are attached. At the free ends of these arms are rotating brushes worm-driven by electric motors. At each side are two vertical pipes pierced with holes through which water sprays on to the car prior to scrubbing by the brushers, and at the rear ends of the machine are additional spray pipes for rinsing the car after the scrubbing. The electric motors and the water valve are automatically actuated by means of switches inserted in the trolley wire so that the entering car starts the motors and opens the water valve. As the car passes out the second switch shuts off the motors and the water supply.

As the cars approach the washer, the front and rear ends are wet with a hose and scrubbed by hand with brushes. The operator then starts the car and as it passes the switch the water is turned on automatically.

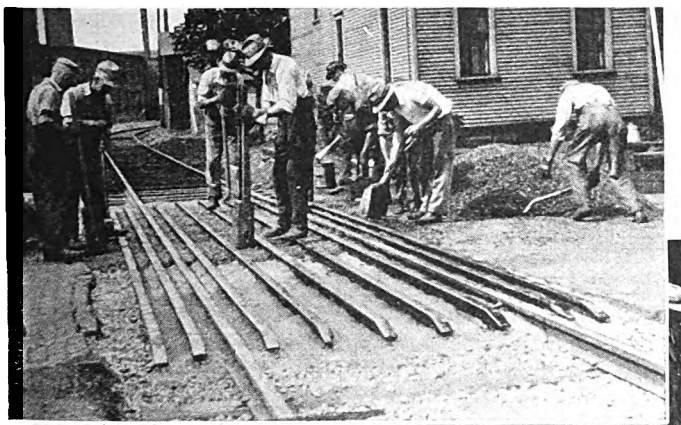
Digitized by Google

On the section of the trolley wire which supplies the car while it is passing through the machine, there is a series connected resistance to reduce the speed to about 1.5 m.p.h. The time taken in passing through the machine is approximately 1½ minutes. Including the time for scrubbing the ends, it is possible to put through approximately fifteen cars per hour.

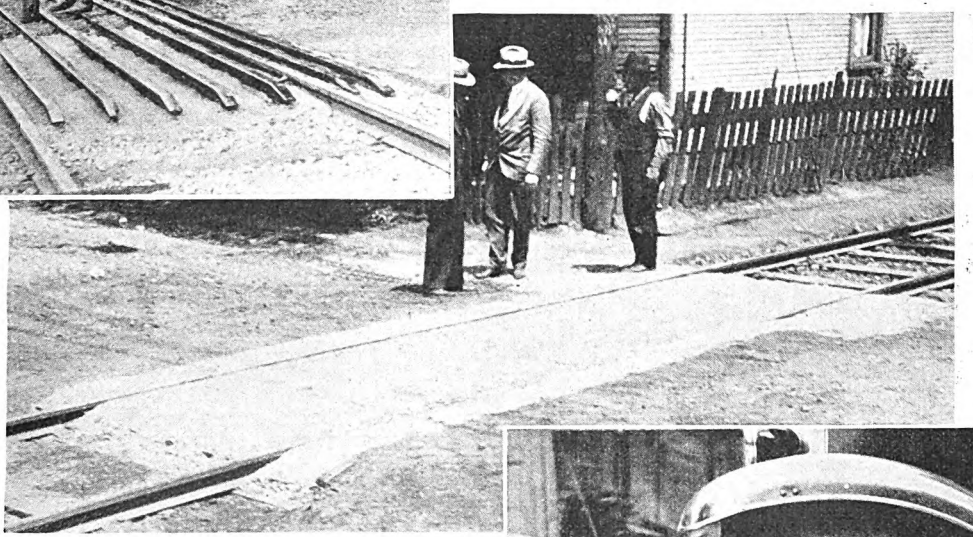
Formerly fourteen men were required to wash the cars on a nine-day schedule. At present, seven men are able to wash the cars on a six-day schedule, with a much better appearance resulting. Installation of the automatic machines at five of the largest carhouses on the system has resulted in an annual saving of $28,000 per year, entirely made up of labor economy.

Grade Crossing Constructed for Heavy Vehicular Traffic

OBJECTIONABLE grade crossings which experience considerable vehicular traffic on the lines of the Stark Electric Railway, Alliance, Ohio, have been improved by the construction of a new type of permanent crossing. This has replaced the plank construction in several cities. Scrap steel rails are used with a cold pack paving material.



Cold pack is firmly tamped between rails of the crossings used by the Stark Electric Railroad

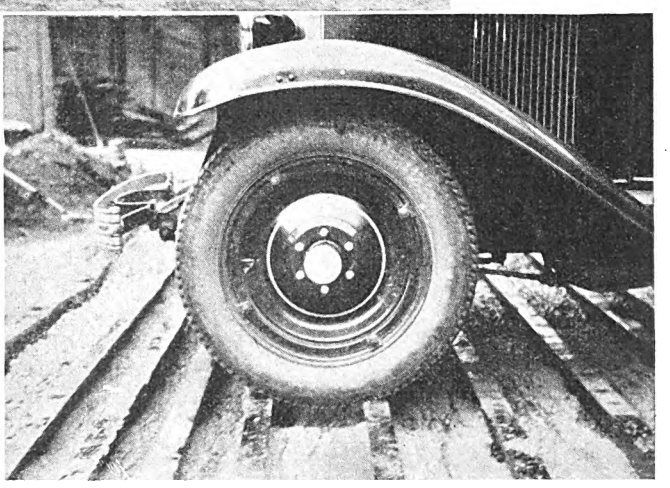


Highway crossings made with scrap rails and macadam filler give a uniform surface and last better than those made with planking

Where a crossing is to be constructed 70-lb. running rails with tie plates are placed on new creosoted ties ballasted with No. 34 slag. Joints are welded. Five lengths of scrap 70-lb. rail are placed between the running rails. Two other lengths are placed outside each running rail. The two outside rails, the running rails and the first intermediate rails are 6 in. apart. The three other inside rails are about 9 in. apart. All rails are spiked to the ties. The base and web of the rails placed between the running rails are cut off about 1 ft. from each end. The remaining heads are bent down to an angle of 45 deg. in order to prevent them from catching snow plows or other equipment operating over the crossing. Under the five intermediate rails and one outside rail on each side hardwood strips of the same thickness as the tie plates are nailed to the ties to bring all rails to the same height. The two outermost rails are therefore ½ in. below the rest.

After the rails have been laid No. 34 slag is tamped between the ties to the bottom of the rails, and above this No. 7 slag is used as a filler. Upon this a cold pack is laid up to ½ in. above the intermediate rails. Before this step, however, the slag and the rails are painted with Headly oil to make the cold pack adhere to the base. The cold pack, which is a patented product, is composed of slag and tar, mixed under heat, as the basic materials. It is tamped into place in small quantities to insure a well packed finished surface. Finally, No. 7 slag is sifted over the cold pack to take up the excess tar. No flangeway is provided, as the wheel flanges will cut their own clearance after a short time.

Crossings of this type have been constructed in the cities of Canton and Salem, Ohio, where traffic exceeds 1,500 vehicles per day. The same type of construction is to be installed on a crossing where the motor traffic will be about 10,000 vehicles per day.



Rails are spaced close enough to bear vehicular loads even without the paving

Lamp Cord Used for Controller Testing*

By J. Munford
Electric Foreman, Ottawa Electric Railway
Ottawa, Canada

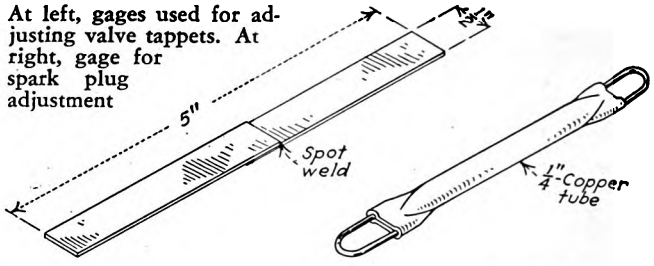
WHEN no test lights are available to test controllers for grounds, a piece of lamp cord is used instead, in the shops of the Ottawa Electric Railway. One end of the cord is connected to the bottom of any high-resistance unit on a bell interrupter. By using a screw-driver to ground various reverse fingers to the frame of the controller, open motor circuits can be located easily. This makes a handy emergency test if the conventional test lights are not available.

Simple Feeler Gages*

By Hoy Stevens
Assistant Superintendence of Maintenance Cleveland Railway

WHERE adjustments of various sorts must be made on motor coaches with definite permissible tolerances, feeler or limit gages have given the simplest and quickest method available to determine acceptance or rejectance of the work. Two places where this type of inspection has proved desirable are on valve tappets and spark plugs.

A maximum and minimum limit gage for adjusting tappets was made in the Cleveland Railway shops by spot-welding together two 3x½-in. strips of steel feeler gage stock, of which one piece is 0.004 in. thinner than the other. The thicknesses have been selected so that if the thin end will go between the tappet and the push rod while the thicker one will not, further adjustment is unnecessary. New adjustments are made to within these limits. The appearance of the gage is shown in the illustration.



At left, gages used for adjusting valve tappets. At right, gage for spark plug adjustment

The second gage illustrated has been made for adjusting spark plugs. Here, two 3-in. lengths of piano wire have been looped and inserted in the end of a 3-in. copper tube of ¼-in. diameter. One of the wires is 0.002 to 0.003 in. smaller than the other. Gages of this sort are furnished to all workmen who have use for them.

Filling Sweeper Broom Blocks by Machine*

By Terance Scullin
Superintendent Equipment and Buildings
Cleveland Railway

SWEEPER broom blocks of the Cleveland Railway are now made with steel holders in a filling machine designed in the shops. The broom holder consists of a half-round channel section, closed at the ends. A locking section has lugs which pass through the channel section when the steam-heated rattan is pressed into shape by the air-operated cylinder. Pins are then placed in the holes of the lugs, binding the sections firmly together.

Under the old system it took 2½ hours to fill a wooden broom block by hand, while with the new system two men can fill sixteen of the new type broom blocks in an hour. By the use of steel holders in place of the old wooden ones, a saving of 33⅓ per cent in holder replacement was made.

*Submitted in Electric Railway Journal Prize Contest.

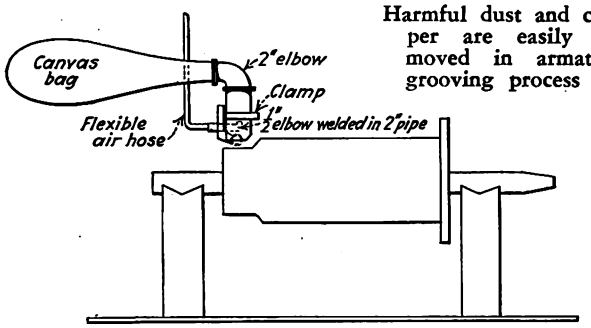
Copper and Mica Dust Collected on Commutator Slotter*

By H. J. Beadle
Equipment Engineer
Dallas Railway & Terminal Company

FOR the removal of copper and mica dust from the surrounding air during the process of grooving a railway armature, it was decided to use in the shops of the Dallas Railway & Terminal Company, a device based on the ejector principle. The device is simple and cheap, and uses very little air.



Harmful dust and copper are easily removed in armature grooving process

A pipe clamped to the bracket carries the saw of the grooving machine. The diameter is 2 in., so as to fit down over the saw. Inside the 2-in. pipe is a ½-in. elbow which is welded to the outside of the pipe and extends outside and beyond it for 2 in. A flexible ½-in. hose is connected to the short piece and delivers the air to the ejector. A canvas bag, placed at the end of the 2-in. pipe, receives the copper filings and mica dust.

Repairing Switches for Portable Crossovers*

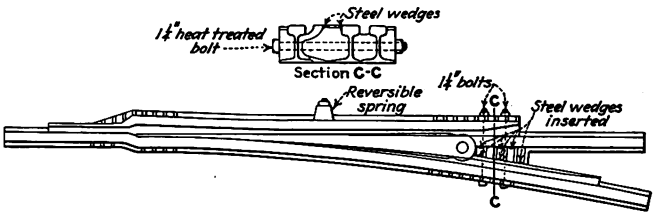
By E. B. Spenzer
Special Work Engineer
Cleveland Railway

LOOSENING of the heel rails in the casting is the first sign of failure in iron-bound switches used in portable crossovers. Immediately afterward the tongue starts to work loose and soon loses its bearing at the heel and pin. It then shears off the heel fastener, without which it is unfit for service, the tongue jumping in the bed during the passage of cars and causing frequent derailments.

Practically all the 44 switches of this type belonging to the Cleveland Railway have had the heel rails work loose. Otherwise they were too good to scrap. The following method to repair them was devised, and the work was done by the local manufacturer who furnished them originally.

New Maintenance Contest Begins on Nov. 1

SEE RULES ON PAGE 701



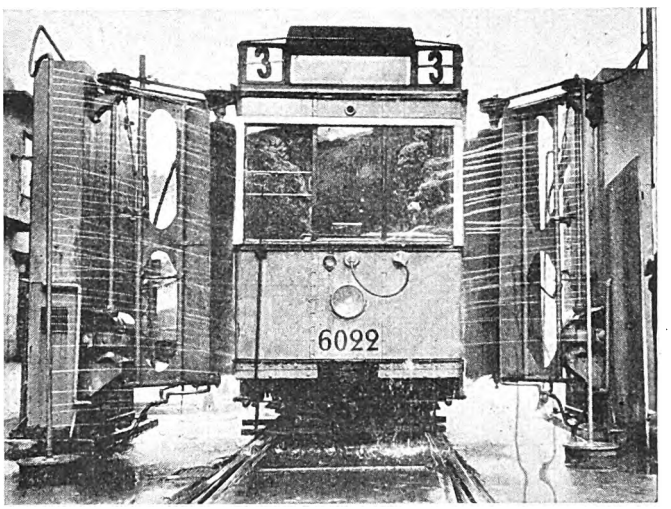
Worm switches for portable crossovers are repaired in Cleveland by bolting up and welding the damaged parts

First, two holes were drilled through the iron casting and rails at the heel and 1¼-in. heat-treated bolts were placed in the holes and pulled up as tightly as possible. Then small steel wedges, ⅛ in. thick and 2 in. wide were driven between rail and casting and spot welded to the rail. The remaining space was filled with spelter.

Next the tongue was refitted by spot welding on the pin and grinding off the excess metal until a bearing as good as possible was formed. A new heel fastener was fitted on and the switch tread ground at the heel to a good running surface. The other repairs consisted of building up worn guards at the heel and toe and replacing the necessary shoes on the base.

This method of repair has been extended this year due to the excellent results under traffic with switches previously repaired. The life of the switches has been doubled or more than doubled at a cost of $60 per switch, or 17 per cent of the cost new.

Berlin Street Cars Washed by Machine



Modern car washing apparatus used in Berlin, Germany

MODERN car-washing machinery has recently been installed by the street-railway in Berlin, Germany. This consists of vertical perforated pipes placed on both sides of the wash track together with a pair of motor-driven revolving brushes. As with similar apparatus used by a number of electric railways in this country, the car moves slowly through the washing machine where it is first sprinkled and then scrubbed. The operation is simplified by the fact that the cars have straight sides as shown in the accompanying illustration. All cars are cleaned in this way every morning before being placed in service.

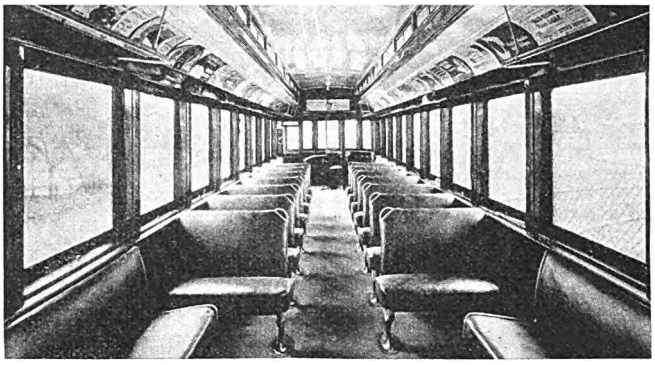
Seating Capacity of Cars Increased in Winnipeg

REMODELED cars have been recently placed in service by the Winnipeg Electric Company. Work on these cars has been in progress in the shops of the company since July with a crew of 246 men. The mechanical equipment has been thoroughly overhauled



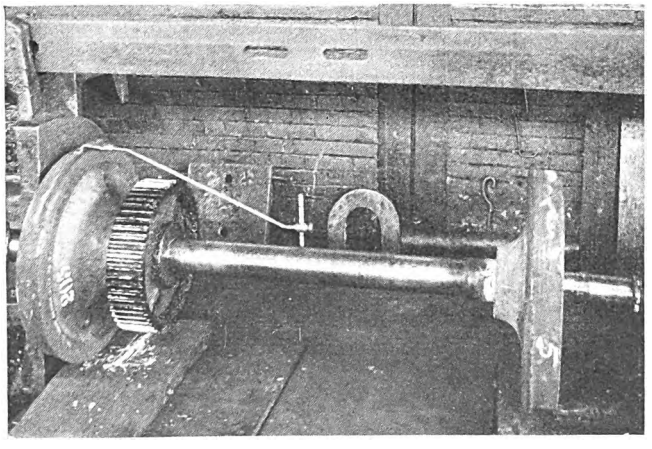
New cross-seats installed in remodeled cars at Winnipeg have increased seating capacity from 39 to 51

and renewed where necessary, and the interior has been redecorated in a more pleasing manner. Facilities have been provided for front exit to avoid the congestion experienced every winter by passengers crowding toward the rear end to alight. Slated flooring has been replaced with battleship linoleum. The seating capacity of the cars has been increased from 39 to 51 passengers by the installation of new cross-seats at a cost of $600 per car. These seats embody the latest design of interior car equipment, having leather surface and spring cushions.

Gage Makes Wheel Mounting Easy*

By Terance Scullin
Superintendent of Equipment and Buildings
Cleveland Railway

FINDING the location of the wheel first pressed on the axle is facilitated by use of a gage adaptable to all wheel sizes, which was developed by the Cleveland Railway. The gage consists of a steel rod, bent as shown in the illustration, with a casting on one end which is designed to rest on the tread and against the flange of the wheel, while the other end has a drilled knob with a knurled setscrew. This device holds a $\frac{5}{6}$-in. round steel rod about 7 in. long, pointed at one end. The setscrew fits into V-cuts in this rod spaced at the necessary distance to conform to wheels of different sizes. By making a punch mark at the center of the axle, it becomes a very simple matter by using the gage to mount the first wheel at the proper distance from the axle center, a job which has heretofore been very difficult.

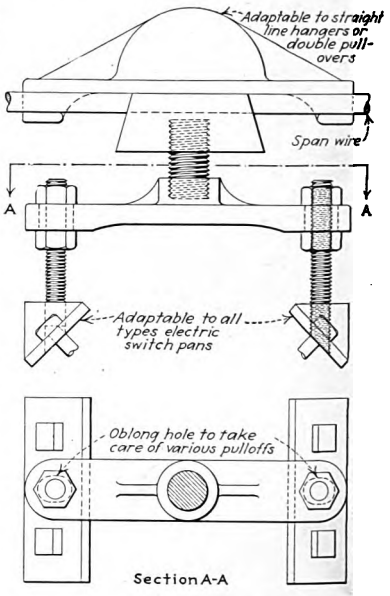


Locating the first wheel on the axle is facilitated by a gage designed in the shops of the Cleveland Railway

Adjustable Hanger for Switch Contactors*

By H. A. Brown
Foreman Return Circuit, Switch and Signal Division
Cleveland Railway

ELECTRIC track contactors on the Cleveland Railway are set and held in position by an adjustable hanger which was developed by the switch and signal division and has been adopted as standard. This hanger, which is readily adapted to any type of overhead contactor, is shown in the illustration. A casting designed for the purpose fits the top of the contactor side bars on either side. It is provided with a boss drilled and tapped to take a $\frac{5}{8}$-in. stud. A cross-member, with oblong holes, is placed over the studs and a bell type hanger is screwed into the center of the cross-member so that the contactor may be attached to the span wire. By raising or lowering the stud nuts below the cross-member, the proper position for the contactor in relation to the trolley wire is found, and the position is held by tightening the stud nuts above the cross-member.



Adjustment of electric track switch contactors is made easy by this hangar designed by the Cleveland Railway

This device replaces the old method, by which the overhead contactors were held in position by driving a staple in each of the contactor side bars, after which it was tied to the span wire with pieces of small wire. Breakage of these small tie wires would permit the contactor to turn on the trolley wire, resulting in switch failures. At best, the device was unsightly and was not satisfactory. The new device has resulted in a great reduction of electric track switch failures and a considerable cut in labor costs. When installed over the trolley wire it has a neater appearance than the old device. The hanger is easily adaptable to all types of electric switch pans.

When Should Contact Line Be Renewed?

By Angus Scott
Assistant Superintendent of Overhead Lines
Cleveland Railway

The author proposes a formula based on relative costs of replacement and repairs

IN CONNECTION with the renewal of contact wire, the statement one hears most frequently advanced by operators is: "Take it down before it falls down." This policy is, however, productive of much waste. It is the purpose of this article to show that a better statement is: "Take it down when it costs too much to keep it up."

Contact wire renewal is divided into three general classes; namely, pieces, spans, and a complete mile or section of line from section insulator to section insulator. It is comparatively simple to determine when to renew a short piece of wire, as at an acceleration point, but to decide when to renew an entire section of line involves a number of factors. One of the chief considerations is that of taking down some wire and materials still possessing considerable capacity for wear along with the worn-out wire. The problems then presented are: (1) Should the line be repaired or restrung? and (2) Is it more economical to take down some good wire along with the worn-out wire than to repair the bad sections?

For example, consider a new 1-mile section of line on a street with varying grades and approximately nine car stops, some at the start of the grades and others at coasting points. The stops will vary in importance and the number of cars stopping will likewise vary. The differences in wire wear or burning will correspond. Then, too, some of the grades will be more severe than others, with unequal wear on the contact wire due to arcing.

After a certain number of car movements, it will be necessary to cut in pieces or spans in the places where the wear is greatest in order to maintain a suitable factor of safety, say, 0.250 in. on No. 00 round trolley wire. As time goes on the original mile will contain stretches of wire of varying cross-sections. The inspector would indicate such successive areas as follows: good, bad, good, fair, good, fair, bad, fair, etc.

Up to this point, the economical procedure in maintenance would be to cut out worn parts and replace with new wire. After a certain time this piecing fails to result in any economy on account of the labor involved, the maintenance of expensive fixtures such as splicers, and the cutting out of short pieces of wire at hard spots or acceleration points, such wire having been installed on former maintenance programs. In addition to the foregoing factors, wire which would be economical to repair in one area would not be considered so in another, due to the number of car passes.

Starting with these general facts, together with the assumptions granted, a formula is proposed for contact wire replacement:

When the over-all cost of annual repairs, including splicers, etc., aside from the normal ear replacements, approximates one-half of the cost of restringing, the contact wire should be renewed if the line receives 200,000 *or more car passes per year.*

Before renewing a section of wire on this basis the practice would be to determine sufficiently in advance just when replacement should be made in the area involved. Upon reaching this decision, all maintenance and renewal of fixtures should be stopped in this area. The time allowed before renewal should be sufficient to obtain maximum life from all the fixtures in the area.

Analyzing the cost of renewal and of repairing a mile of wire, such as the one just described, we find comparison between restringing and repairing with short pieces will be as shown in the table. The sum of $129.41 represents the actual difference between repairing and restringing the line. This will, of course, vary with the price of copper, being lower as the price is reduced.

From the above it readily may be seen that to repair wire in such condition on a line which averages 200,000 car movements per year would not be economical, since

Comparison of the Cost of Restringing a Mile of 00 Trolley Wire With the Cost of Repairing It

Restringing		
Labor for stringing, insulating and aligning	$ 52.57	
1 mile of 00 wire at $19.65 cwt.	425.99	
Fixtures—ears, splicers, etc.	40.90	
Total cost of restringing	$519.46	
Salvage value at 14 cents per lb., wire 70 per cent by weight	221.05	
Actual renewal cost		$298.41
Repairing		
Labor for stringing 1,000 ft. of wire at 5 cents per foot	$ 50.00	
Ear renewal on periods skipped	20.00	
1,000 ft. of 00 copper, salvage allowed	40.00	
Ears, splicers, armor, etc.	29.00	
Maintenance above normal on repaired line per year	30.00	
Cost of repairing for 1 year		$169.00
Net cost of restringing		$129.41

maintenance costs on a repaired line increase rapidly over normal maintenance due to the renewal of splicers and trolley armor. After operating for a year over the line following such repairs, many of the fixtures installed would have to be renewed, and also much of the original wire which was not replaced the year previous would require piecing. When the cost of this is calculated, it will, in all probability, be great enough that it will be decided to restring the entire line rather than maintain the necessary additional splicers and fittings. By restringing the line at this time, the labor and material of the previous repairs would be practically wasted. Thus it would not be economical to retain the structure by repairs for the additional year's service.

In the cost of repairing the line there is an item of $20 for labor and material for ear renewal periods skipped. This item is included there because if it were decided to restring the line rather than repair it, ear renewals would be skipped for a number of months, saving the labor and material which would be required if the line were repaired.

Results from actual experience show that the labor costs of repairs and inspections on a line remain fairly constant up to about 500,000 car movements. Then the cost of maintenance increases rapidly due to the cutting

Digitized by Google

in of pieces or protection of acceleration points. Costs should be computed when No. 00 standard hard-drawn trolley wire approaches 1,000,000 car movements. Extensive repairs undoubtedly will be required then on a line averaging 200,000 car movements per year depending, of course, on the kind of wire and class of service. If it is found that the cost of repairing ($169) is approximately equal to one-half the cost of renewal ($298.41), the wire should be restrung.

The writer does not contend that the formula proposed is applicable to all wire renewals. It is his belief, however, that a formula covering wire renewals could will be developed by the industry. His experience suggests that the straight line formula proposed, rather than the parabolic formula of increasing annual expenditures, will apply very well to contact wire renewals.

Motor Field Shunting Gives Old Cars New Pep

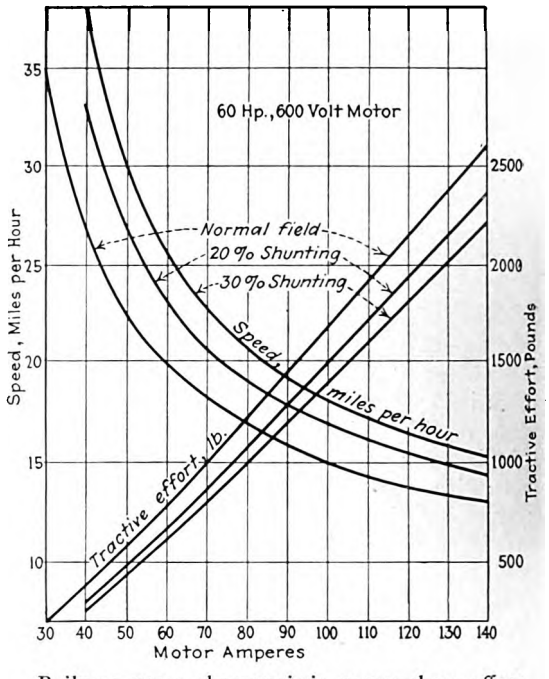
By G. L. Moses
Renewal Parts Engineer
Westinghouse Electric & Manufacturing Company

IMPROVEMENT of schedules is possible by the adoption of a relatively simple means of speeding up street cars. It has long been known that shunting part of the current of a series railway motor around the field results in an increase of speed. Recent agitation to increase schedule speeds has led to extensive investigations of the commercial feasibility of such a scheme. Field shunting is accomplished by the addition of a few switches with a controlling relay and helical resistor units. This provides an extra accelerating point after the full parallel running position has been reached and increases the free running speed of the car. Tests conducted thus far indicate that considerable increases in schedule speeds are possible in many cases with field shunting.

From an economic standpoint this is of great value as the increase in schedule speed permits better service with the same equipment, or reduces the amount of equipment required for a given service. The cost of the equipment plus the cost of installation is slight compared to the benefits which can be derived from field shunting properly employed. Field shunting is equally applicable to drum or remote control and requires little or no wiring change. Wherever operating companies intend to operate existing cars over the same line at higher speeds, the possibilities of field shunting are well worth a careful investigation.

This scheme has its limitations. Faulty overhead construction, permitting the trolley to disengage, is liable to cause motor flashing. Some types of motors are more adaptable to field shunting than others. These are motors that have a reserve capacity and are free from commutation difficulties with weakened field strength. Helical, edge-wound resistors are used as field shunts on account of their light weight and their inductive characteristic, which reduces the tendency of commutators to flash. It is advisable to use a current limit relay to insure that the field shunting switches are not closed before the motor current is reduced to a safe value. If this is not done, the motors may be unreasonably overloaded, and have a decided tendency to flash.

The percentage of the motor field current which may be safely shunted depends upon the construction of the motor and upon its application. It is necessary to keep within the proper current limits so that excessive heating will not result. Weakening a motor field naturally has a detrimental effect on commutation. Therefore, if we disregard the heating effect, the ultimate limits of shunting is determined by the result on commutation. Each particular application represents a special problem and is worthy of careful consideration. Each operator should try out the scheme on his own equipment and service which he desires to speed. He can then best determine the operating advantages which can be obtained within the limits of his particular application.



Railway motor characteristic curves show effect of field shunting

Copenhagen Orders Experimental Cars

WITH the idea of modernizing its rolling stock, all of which has now been in service for at least ten years, the electric street railway in Copenhagen, Denmark, has built a motor car and a trailer of improved design. Owing to the narrowness of the streets and the sharp curves, single-truck motor cars and trailers have been used in the past. The new cars are of the double-truck type, the motor car seating 28 passengers and the trailer 26. In general the cars follow American design practice, the motor car having end platforms and the trailer a center platform. The over-all length of each car is 46 ft. $4\frac{5}{8}$ in. and the width 6 ft. $10\frac{3}{4}$ in. It has been decided to spread the track centers so that the width of future cars can be increased to 7 ft. $2\frac{1}{2}$ in.

Considerable interest centers in the motor and truck design. Four air-cooled motors rated at 21 kw. at 275 volts and 1,200 r.p.m. continuous load are connected two in series. The drive is through single reduction gears with a ratio of 6 to 1.

If the tests made with these cars show that they meet the demands of Copenhagen's traffic, it is understood that orders for a large number will be placed during the next twelve months.

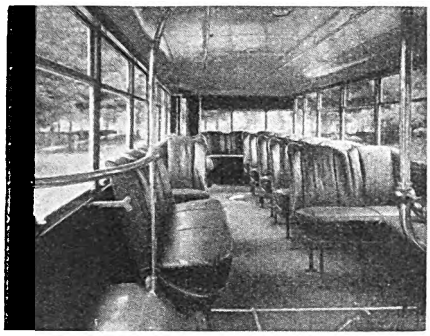
NEW PRODUCTS for the Railways' Use



Seating arrangement has been developed to facilitate circulatory loading

Small-Capacity Bus With Circulatory Loading

SIMILARITY of construction detail to the larger types has given to the small-capacity, single-engine bus, recently developed by the Twin Coach Corporation, the advantage of circulatory loading. Front-entrance and rear-exit facilities, together with a novel seating arrangement to fit, have made this feature possible.

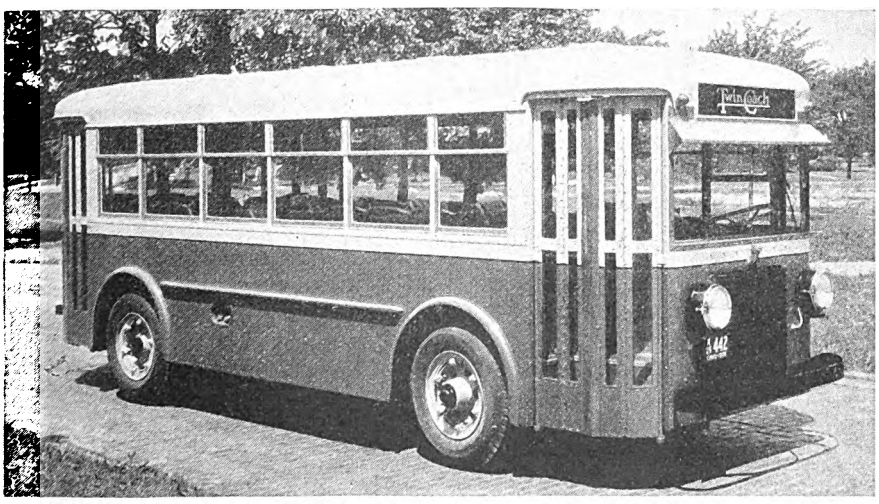
Construction of body and frame is of high-grade steel; body posts are of cold-rolled T-section. All metal joints are painted and primed before assembly with rust-resisting paint. Body sides, ends and roof are sealed with compound. To prevent corrosion, panels are riveted to the body posts and roof carlines with specially treated rust-resisting rivets.

The doors are air operated, each having a 23-in. full opening. The front entrance door is placed ahead of the front wheel, and the rear exit door is placed behind the rear wheel. Seating equipment consists of two-passenger, bucket type seats on the left side and either individual bucket seats on the right side at an angle or longitudinal wheelhouse seats at the front and rear with single forward seats between them. The aisle space provided with this arrangement varies from 15 to 18 in. Seating capacity varies from 20 to 24 passengers depending upon arrangement of seats.

The bus is equipped with a new $4\frac{1}{8}$-in. bore Twin Coach engine, developing 90 hp. Ample brake capacity and long life are assured with four-wheel air brakes using large-size shoes and drums. The rear axle has a bevel gear drive, and the front axle has an especially heavy I-beam section. Both are Timken. The tires are the new 9.00x18 size, with a capacity of 3,600 lb. per tire. Drive shaft is mounted in one midship bearing supported by special rubber mountings to eliminate noise. Steering mechanism is the Ross cam and lever type. Electrical equipment and air brake equipment accessories, transmissions, clutch and drive lines are the same as found in the large Twin bus.

GENERAL DIMENSIONS

Over-all length, without bumpers and visors	21 ft. $3\frac{5}{16}$ in.
Over-all length, with bumpers and visors	22 ft. $10\frac{3}{4}$ in.
Over-all height, loaded	$99\frac{1}{2}$ in.
Over-all width	86 in.
Wheelbase	140 in.
Tread—front and rear	6 ft.
Turning radius—approximate	28 ft.
Interior headroom	73 in.
Step height from ground, unloaded	16 in.
Floor height from ground, unloaded	$28\frac{3}{8}$ in.
Road clearance, minimum under front axle	7 in.
Road clearance, minimum under rear axle	10 in.
Weight, approximate	10,000 lb.



Front entrance and rear exit facilities are incorporated in design of new small-capacity bus built by Twin Coach

Paint to Provide Protection Against Corrosion

AS THE result of research carried out by the chemical and technical staffs of E. I. du Pont de Nemours & Company, a product known as DuLux has been developed, which imparts some of the advantages of Duco to finishes of the paint and varnish type.

It is stated that the product is based on a film-forming material that is an especially developed synthetic chemical compound exceptionally resistant to disintegration. It differs radically in this respect from the natural oils and resins generally used in the manufacture of paints, varnishes and enamels.

A coating of this product dries more quickly than the ordinary finishes, thus greatly reducing the time during which freshly coated surfaces are subject to marring by insects or dust. It is claimed to be unusually resistant to rain damage during the drying period. Laboratory tests, which have been confirmed by thousands of panels exposed to the elements in various sections of the United States, indicate that the new product provides surface protection for an unusually long period of time.

DuLux is now available for industrial uses, including the finishing of machinery and the coating of structural steel, bridges, freight cars and other places where resistance to weathering and corrosion is required.

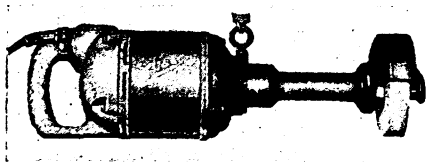
On the face of the meter, in large white figures, is indicated the fare to be paid. The extra fare for additional passengers or extras is also clearly indicated on the meter face. Sets of visible totalizers are placed on the back of the meter to give the cab operator the necessary information concerning total paid miles, total dead miles, number of trips, number of passengers carried, number of extras, total amount of money collected for the day and income per cab-mile.

Portable Hand Grinders



Grinders are equipped with 10 ft. of rubber cable and connector plug for operation from lamp sockets

TWO portable hand grinders rated at 1 hp. and 2 hp. capacities, for both direct and alternating-current operation, have been placed on the market by the Hisey-Wolf Machine Company, Cincinnati, Ohio. The motors of these grinders are rated for continuous duty and the mechanical parts are designed for heavy-duty service. They are provided with ball-bearing motors and Timken roller bearing grinding spindles.

The 1-hp. grinder has a no-load speed rating of 3,400 r.p.m., and a net weight of 85 lb. The 2-hp. grinder has a no-load rating of 2,200 r.p.m., and a net weight of 320 lb. The standard equipment consists of grinding wheel, adjustable and approved steel wheel guards, 10 ft. of rubber cable, connector plugs and a suspension spring.

The manufacturer recommends the use of a 2-hp. machine and a 1-hp. machine for economy. When the original 10-in. diameter grinding wheel for the 2-hp. grinder is worn to 8 in., it can be transferred to the 1-hp. machine operating at a higher speed, thereby maintaining the original efficiency.

New Maintenance Contest Begins on Nov. 1

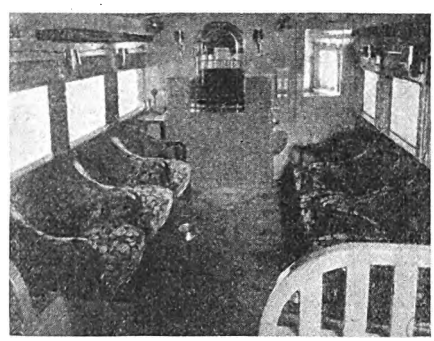
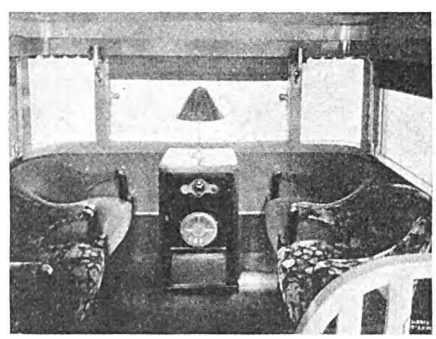
New Mack "salon club car"

Mack "Salon Club Car" Bus Offers Luxury for Long-Distance Travel

DESIGNED for luxury and riding comfort in long-distance travel, a Mack "salon club car," with a capacity of 23 passengers, has been introduced. Radical departures from conventional designs have been made in the seating arrangement and interior equipment. The bus is divided into three sections and the body is mounted on a Mack Model BK chassis.



Luxuriously furnished salon is separated from the driver's section by a bulkhead



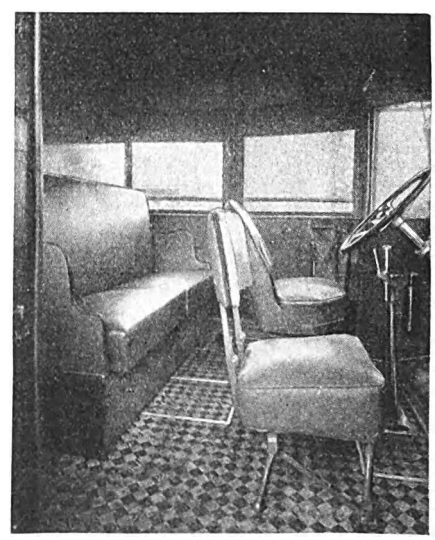
Solarium at the rear contains a radio and heating unit placed in an attractive cabinet

The driving compartment is separated from the passenger section by a built-in bulkhead which materially reduces the sound of the motor. Isolation of the driver and steward from the passengers is thus obtained. Club chairs of the railroad type have been adopted to insure comfort and satisfactory relaxation.

Entrance at the front is through a cabin-lounge, seating five passengers. If necessary, this lounge may be made up into two berths for the crew. A side door leads into the salon which accommodates ten persons. Six of the seats are of the movable club-chair type. Built into the forward bulkhead is a buffet, water cooler and small refrigerator. Luncheon or refreshments may be served by placing small table attachments on each of the arm chairs and by setting up the Pullman tables. These tables may also be used for card playing.

From this middle section, a 16-in. aisle leads between four back-to-back seats, above the wheel-housings, opening into a solarium having four movable club chairs. The solarium contains a radio and a heater, concealed within the radio cabinet. Here the window construction permits an uninterrupted view through both sides and rear.

Windows are equipped with roller screens, keeping out dirt while admitting air. Electric fans and ventilating fans in the rear portion of the roof change the air every 60 seconds.



Front lounge may be converted into berths for the crew

LATE NEWS

Rockford, Ill.—A. P. Lewis of the Rockford Electric Company has indicated that new trolley buses will be operating here by Dec. 1. The new buses will supplant street cars on the North Church and North Main Street lines, the Harlem Boulevard and connecting routes.

✦

Vancouver, B. C.—The Prince George City Council has tentatively approved an agreement under which the Canadian National Railway will be supplied with electric power from the municipally owned plant for five years, on a sliding scale.

✦

Boston, Mass.—Boston, Revere Beach & Lynn Railroad stockholders have approved a plan to issue $2,200,000 of bonds, the proceeds to be used to retire $1,000,000 of 4½'s at 103 and $1,000,000 of 6's at 102.

✦

St. Louis, Mo.—The St. Louis Public Service Company is operating one-man cars on its Southampton line. For this service 40 cars were rebuilt and equipped with automatic doors, electric heaters and leather-faced seats. The cars have pedal control. With an increase in the number of cars the time between cars has been cut to 1½ minutes during the rush hours and to 4½ minutes in non-rush periods.

✦

Trenton, N. J.—The State Board of Public Utility Commissioners has approved the application of Public Service Co-ordinated Transport to operate twelve additional buses between West Orange and Newark, and Public Service Interstate Transportation Company to operate ten extra buses between Orange and Newark.

✦

Louisville, Ky.—By resolution adopted on Oct. 15 a committee composed of John Stites and Charles A. Heuser is to inquire into any additional economies which seem advisable for Louisville Railway and report at the next meeting with recommendations for any eliminations or reductions regarded as possible without impairing company efficiency. A resolution was also endorsed by the directors ordering $100,000 to be paid on $600,000 of demand notes at the local banks, to reduce indebtedness and lessen interest charges. Meanwhile, action on dividends has been deferred.

✦

St. Louis, Mo.—President Neun, of the Board of Aldermen, St. Louis, Mo., on Oct. 10 referred to a joint aldermanic committee the report of the transportation survey commission which contained recommendations for the improvement of mass transportation in St. Louis. Mr. Neun urged the joint committee to study the report carefully and submit such legislative measures to the entire board as deemed advisable to carry out the recommendations of the commission.

Association Affairs Reviewed by Executive Committee

Financial Affairs in Good Shape. Committee on Financing of New Cars to Be Appointed. Cleveland Railway Accepts Journal's Maintenance Plaque

MANY phases of the work of the American Electric Railway Association were discussed at an executive committee meeting held in New York on Oct. 10. The report of the committee on policy, presented by G. A. Richardson, chairman, recommended that no definite action be taken at this time concerning the plan of having exhibits in alternate years at A.E.R.A. conventions. The policy committee also recommended the appointment of a committee on car financing. Both recommendations were approved by the executive committee. Work of the publicity committee was outlined by Labert St. Clair in the absence of Barron Collier, chairman. At the request of Col. J. H. Alexander, chairman of the membership committee, its report was presented by F. C. J. Dell.

Details of the financial status of the association were presented by F. W. Doolittle, chairman of the finance committee. He stated that due to careful management and certain fortuitous circumstances, the financial status was better than had been anticipated. The committee recommended the continuance of the present 10 per cent reduction from the regular schedule of dues. This was approved by the executive committee.

Reporting for the committee on national relations, C. D. Cass, general counsel of the association, spoke of the recommendations of the National Association of Motor Bus Owners on the subject of interstate bus regulation. The executive committee indorsed the resolution of that association. W. E. Wood, chairman publications committee, said efforts made to secure wider distribution of *Aera* had not met with marked success, and that the publication committee was planning to hold a meeting in the near future to consider this problem.

Advantages resulting from the work of the committee on insurance were outlined by H. B. Potter, chairman. He pointed out that the rate reduction made by the stock fire insurance companies through the work of the committee had resulted in an annual saving to the industry greater than the annual expense of running the association.

Charles Gordon, managing director, spoke briefly of his recent activities. He said that studies made by the association had developed the fact that travel by auto was 23 times as hazardous as travel by trolley on the basis of fatalities per passenger-mile. Mention was made of the work of the presidents' conference committee, and Mr.

(*Continued on Page* 717)

COMING MEETINGS

Oct. 29-30—Iowa Electric Railway Association, Des Moines, Iowa.

Nov. 12-15—National Association of Railroad and Public Utility Commissioners, annual meeting, Charleston, S. C.

Indianapolis Deposits Satisfactory

Security deposits for the proposed reorganization of the Indianapolis Street Railway is proceeding at a satisfactory rate. Secretary Wichmann of the committee representing owners of the Citizens' Street Railroad 40-year 5 per cent bonds reported 70 per cent surrendered with no withdrawals. John P. Collett, secretary of the group holding Indianapolis Street Railway preferred stock, declared that more than 30 per cent of this stock had already been surrendered and that deposits of large blocks are assured. Approximately 50 per cent of the bonds of the Indianapolis Traction & Terminal Company have been deposited. Plans for the reorganization of the railway and the sale of its properties to two new corporations with approximately $9,700,000 of new money for rehabilitation being supplied by the Midland United Company, an Insull organization, were announced in the ELECTRIC RAILWAY JOURNAL NEWS for Oct. 11.

More Time for Chicago Acceptance

The Chicago City Council is to consider an extension of the date before which the merged transportation company must accept the new co-ordination franchise. To this end the local transportation committee of the council has recommended that the time limit be put forward until Jan. 31, 1931. The date set in the ordinance is Oct. 31, but it was agreed that the consolidation could not be effected by that time. The date proposed on behalf of the companies is between March 10 and 15 of next year. Representatives of every class of security except one have agreed to the merger. This exception is the representatives of the capital stock of the Chicago Railways, the west and north side surface lines, now in the hands of receivers, thus adding a technical complication but one not expected to militate against the consummation of the plan.

LATE NEWS

(*Continued from Page 715*)

Decatur, Ill.—The Illinois Commerce Commission has authorized the Illinois Power & Light Corporation to supplant the last of its street cars in Jacksonville with bus service, and has on file an application of the company for permission to make a similar change of service over four routes in Decatur.

✦

Columbus, Ohio—Tracks, cars and substation generator equipment of the Scioto Valley Traction Company have been purchased by the Joseph Schonthal Company, Columbus. There is, in all, 75 miles of track, extending from Columbus to Chillicothe, and from Columbus to Lancaster. Service over the line has already been withdrawn.

✦

New York, N. Y.—Continuance of the hearings on the proposed removal of the Sixth Avenue elevated line of the Manhattan Railway has been postponed to Nov. 3 by the Transit Commission.

✦

Newark, N. J.—Public Service Coordinated Transport, suffered a net loss from operations for first nine months of 1930 of $1,757,289, against profit in same period of 1929 of $305,832, E. A. Tuson, general auditor of company testified before Board of Public Utility Commissioners.

✦

Indianapolis, Ind.—Authority to spend $42,200 for track improvements at two major downtown street intersections in Indianapolis has been granted the receiver of the Indianapolis Street Railway Company by Judge Chamberlain of the Marion Circuit Court. At the same time, the court approved expenditures totaling $255,500 for other track improvements made during recent months. The court stipulated that all such improvements be made out of the current revenue, being opposed to the issuance of receiver's certificates.

✦

New York, N. Y.—Progress on the construction of the city's new subway lines, especially on the shops and yards at 207th Street, reported as 97 per cent complete, appear to insure the opening of the main line of the system under Eighth Avenue in Manhattan in the early Fall of 1931. Initial operation on this line is to be from Fulton and Church Streets to 207th Street.

✦

Erie, Pa.—The Erie Railways plans to substitute bus for trolley service between Erie and Wesleyville, through its subsidiary, the Erie Coach Company, if the Public Service Commission approves.

✦

Dallas, Tex.—Of the $1,373,000 set aside by the Dallas Railway & Terminal Company for the extension and improvement of its property for the current year, $605,000 will be spent in constructing a new viaduct across Trinity River. This work was started recently in accord with an agreement made with the city seventeen years ago. Included in the improvement program were track re-arrangements, purchase of seventeen new cars, the rebuilding of fourteen old cars and the paving of right-of-way on several streets.

The Business Outlook

FUNDAMENTAL though blind forces of human needs are again slowly laying the basis for future recovery since consumption eats steadily into supplies as industrial production lags. Even in building there are clear signs of revival in residential construction. Commodity prices in recent weeks have tended to hold up against the deflation process still under way in securities. As these particular forces become more apparent, business is realizing the necessity of aggressive individual action from the bottom.—*The Business Week.*

Boston, Mass.—Railway and bus fares were reduced materially on Oct. 26 in Reading, Wakefield, Andover, Wilmington and Tewksbury by the Eastern Massachusetts Street Railway. The fares situation in those towns had become unsatisfactory because the zoning system created a number of overlapping fare districts resulting in double fares over some short runs.

✦

Brooklyn, N. Y.—The Transit Commission's service bureau, after a check, reported that while the Brooklyn & Queens Transit Corporation had added more cars when it changed service on the Graham Avenue line from two-man to one-man operation, there were long intervals at times between cars. The cars used in the change were remodeled Brooklyn City Railroad cars, equipped with all required safety devices, but they did not have the treadle step and turnstile fare collector to speed up loading and unloading. This lack is blamed by experts for failure of the one-man system to succeed on this line, one of eight included in the wholesale application of the corporation for conversion to the one-man type last summer.

"Don't Forget, You Pick Up Both of Them"

Memphis Commercial Appeal

Chicago, Ill.—The Government has filed suit to restrain or enjoin the Chicago, North Shore & Milwaukee Railroad from further issuing of securities without first applying for authority from the Interstate Commerce Commission. The petition was filed by Assistant United States District Attorney Joseph A. Struett in United States District Court and alleges that since June 8, 1923, the railroad has issued $42,000,000 in securities without first obtaining consent of the I.C.C. Federal against state authority is at issue.

✦

Dallas, Tex.—Removal of tracks of the Dallas Railway & Terminal Company on South Akard Street and substitution of bus service at the regular car fare has been decided upon by city officials. The Akard line has long been a drag on the rest of the system.

✦

New York, N. Y.—Resolutions expressing opposition to the continuance of the Delaney plan of financing construction of the new city subway system has been adopted by the Merchants Association and also by a group of leaders in several civic organizations, meeting at the Chamber of Commerce of the State of New York. The resolutions urged that the present method of financing the subway work by short-term securities be discontinued and that a policy of issuing long-term bonds be adopted instead.

✦

Hartford, Conn.—The Connecticut Company has been authorized by the Public Utilities Commission to operate bus service in part in substitution for trolley service between Bloomfield and Hartford. Limited trolley service will be afforded residents of Rockwell's Corner on the Blue Hills Avenue line.

✦

St. Louis, Mo.—The St. Louis Public Service Company is installing electric heaters on its cars as quickly as the financial condition of the company will permit. At the present time about 70 cars on the system are so heated. In its final report, the St. Louis transportation survey commission recommended that 800 new cars, electrically heated, be bought, and that the remaining cars on the St. Louis system be equipped with electric heaters as part of the work to be done by the company under a proposed new franchise deal.

✦

Lowell, Mass.—The Eastern Massachusetts Street Railway plans complete substitution of buses for all trolley lines here. No major track replacements will be attempted, trolleys on some lines to be used only through the remaining life of the rails.

✦

Warren, Pa.—The West Ridge Transportation Company, which nearly a year ago acquired the Warren Street Railway, discontinued operation of trolleys on Oct. 18. Buses have been placed in service on former trolley routes and a number of new routes have been established. In starting the bus service, the company carried passengers free of charge the first two days. The Warren Street Railway began operations in 1893. In 1903 interests identified with it formed the Warren & Jamestown Street Railway to operate between Warren, Pa., and Jamestown, N. Y. On Dec. 3, 1929, buses of the West Ridge Transportation Company supplanted the interurban railway service.

Weekly Pass in Portland, Ore.

Weekly passes, to be sold for $1.25 and to be good for any number of rides by any holder, will be instituted by the Pacific Northwest Public Service Company at Portland, Ore., on Nov. 1, or as soon thereafter as details can be arranged. Decision to adopt this change was reached on Oct. 18 at a conference of railway officials with the Oregon Public Service Commission.

The change is to be made at the request of the commission as an experiment. The new rate will be in effect until the close of the year. If the pass system by that time has popularized street car riding enough to increase the company's revenues it will be continued.

A 10-cent cash fare has been in effect since March 6.

Segregation of the railway lines has been a matter of discussion for some time.

Association Affairs Reviewed

(*Continued from page* 715)

Gordon was formally authorized to serve as secretary of this committee. Professor Hirshfeld, chief engineer of the presidents' conference committee, was presented to the members of the executive committee.

President J. H. Hanna presented the annual company award in ELECTRIC RAILWAY JOURNAL Maintenance Contest to Col.

Another Trophy for the Cleveland Railway

J. H. Alexander, president of the Cleveland Railway. Ordinarily this presentation would have been made at the annual convention of the association, but this year the convention was held prior to the conclusion of the contest. In accepting the award, Colonel Alexander expressed his gratification at the success of the Cleveland Railway.

After luncheon, the members of the executive committee heard Hawley Simpson, research engineer A.E.R.A., tell about the growth of the use of private automobiles in the United States. Charts showed that the rate of increase has been arrested. He predicted that the effect of the private automobile upon public transportation had reached its maximum and that this form of competition was unlikely to become more serious in the future than it has been in the past.

Nov. 21 was tentatively selected as the next date for a meeting of the executive committee.

Mid-West Association Plans Equipment Men's Division

A FORWARD-LOOKING step of considerable interest featured the eighth annual meeting of the Mid-West Electric Railway Association held in Miami, Okla., Oct. 9, 10 and 11, when, without a dissenting voice, it was decided to organize within the association an equipment men's division where mechanical department employees could foregather semi-annually for a detailed discussion and comparison of the equipment performance records of their respective railway properties.

Particular attention, also, was paid to the subject of modern mass transportation vehicles. The trolley bus, especially, came in for a great deal of discussion. Pointing out that the trolley bus is not a new development; that 30 years ago it was in use in Europe, and some ten years ago was introduced to North America, F. M. Peters, Chicago district manager, transportation department, General Electric Company, presented two moving picture reels showing the operation of the Salt Lake City and the more recent Chicago trolley bus installations.

H. S. Robertson, presiding over the Thursday and Friday sessions, called attention to the unprecedented competition which many businesses, other than the electric railways, face. Changing conditions may make it necessary, he said, to revise financial structures of existing railway properties; to effect alterations in physical layouts by abandonments, reroutings, new equipment, co-ordination of bus and trolley bus operations, and revision of schedules and headways. In fact, Mr. Robertson concluded, research and study alone must determine what is best suited to meet the situation.

In discussing factors vital to the satisfactory operation of electric railways in cities of 85,000 population and less, F. J. Johnson, railway engineer St. Joseph Railway, Light, Heat & Power Company, stressed modernization, including not only the operation of up-to-date equipment, but also a modern financial structure, modern rates, a modern franchise, and modern service. Equally important, Mr. Johnson urged, was the need for an intensive merchandising. Finally, he urged a careful analysis of operating expenses to the end that economies in numerous small items might be made sufficient to spell the difference between profit and loss.

The Hon. John E. Curtiss, former chairman of the Nebraska State Railway Commission, defended the regulatory commissions, but declared that the interests of the people were generally best served when enlightened managements were allowed a comparatively free hand in working out solutions to the perplexing problems confronting the utilities.

In a paper prepared by S. B. Cooper, manager, general engineering department, Westinghouse Electric & Manufacturing Company, George Gillespie, Kansas City representative of the company, reviewed the progress which has been made in developing equipment for present-day operating requirements.

Claim settlements and the defense of lawsuits were subjects covered by A. T. Bagley, general claims assistant Kansas City Public Service Company. Mr. Bagley reviewed the campaign his own company has been conducting for several months against the practices of "ambulance chasing" lawyers. The change in claim policy has been directed toward cutting down the number of lawsuits, and contemplates, determining if it is not cheaper to dispose of all doubtful liability claims immediately.

In a paper dealing with the solicitation of claims, G. T. Hellmuth, general claims attorney Chicago, North Shore & Milwaukee Railroad, stressed the avoidance of accidents through the more careful selection of trainmen. "Having once chosen our trainmen," continued Mr. Hellmuth, "the next problem is that of training them. We all know how to train new men—at least I assume that we are all readers of *Aera,* ELECTRIC RAILWAY JOURNAL, and the proceedings of the American Electric Railway Association, all of which in the last two or three years have devoted considerable attention to the subject." A third requisite, concluded the speaker, is supervision — constant observation and rigid enforcement of discipline.

As an interesting feature of the first day's session, a first aid demonstration was staged by a five-man team of the Northeast Oklahoma Railroad.

A business session concluded the working program. C. A. Semrad, general manager St. Joseph Railway, Light, Heat & Power Company, was elected president for the forthcoming year; R. P. Woods, Kansas City, Clay County & St. Joseph Railway, was elected first vice-president; and C. W. Gifford, general manager, Des Moines Railway, was elected second vice-president.

Five-Cent Fare to Be Restored in New Jersey

A straight 5-cent community fare on trolley and bus will be restored in New Jersey as soon as mechanical changes can be made in fare boxes. So Thomas N. McCarter, president of the Public Service Co-ordinated Transport, informed the State Board of Public Utilities Commission on Oct. 23. The cash fare now is 10 cents with ten tokens sold for 50 cents.

In a letter to the commissioners Mr. McCarter said:

If the ownership of Transport stood by itself without association with other properties compliance would be economically impossible, but as is well known, Public Service Corporation of New Jersey is the sole owner of the equity of Transport as it is of Public Service Electric & Gas Company, which serves substantially the same portions of the state. It is also well known that despite the difficulties of Transport, Public Service Corporation as a whole is in sound economic condition and though not a utility in the strict sense of the term it is of the highest consequence that it, as the owner of all these properties, should be adequately maintained. In trying out this arrangement we think Public Service is making a substantial contribution to help existing conditions locally. It will be our effort to contribute our share in the development of the state by rendering adequate service in all three of these major utilities. In agreeing to this advanced step we beseech for Transport a continuance of the co-operation of the board, fair treatment by the municipalities and the good will of the public.

Electric Railways Win Bus Maintenance Awards

Winners of the national awards given annually to operating companies in the bus industry by *Bus Transportation*, a McGraw-Hill publication, were announced on Sept. 26 in connection with the fourth annual meeting of the National Association of Motor Bus Operators in Chicago. The winners are: In Class A, for companies operating 3,500,000 or more bus-miles annually in revenue service: first award, United Electric Railways, Providence, R. I.; second award, Community Traction Company, Toledo, Ohio.

In Class B, for companies operating 1,000,000 and less than 3,500,000 bus-miles in revenue service: first award, Blue Ridge Transportation Company, of Hagerstown, Md.; second award, Washington Rapid Transit Company, Washington, D. C.

In class C, for companies operating less than 1,000,000 bus-miles annually in revenue service: first award, Groton & Stonington Traction Company, New London, Conn. There was no second award in Class C.

The awards were given this year for the most outstanding examples of progress made in maintenance methods and practices for vehicles operated by motor carriers in the United States and Canada. In all, there are six awards, divided among three classes of companies operating in either city or intercity service. In each classification, the first award is a medal plaque and a certificate, together with the sum of $500 in money. Second prize in each group takes the form of a medal plaque and a certificate.

What's in *News of the Industry*

A.E.R.A. executive committee meets.

Prospects good for appointment of committee on car financing.

Progress reported on Indianapolis reorganization.

More time likely for acceptance of new Chicago grant.

Full service by bus eventually in Lowell.

"Don't Forget, You Pick Up Both of Them."

Portland to try the weekly pass.

Stirring meeting of Mid-West men.

Five-cent fares back in Jersey.

A national institute of traffic engineers.

Mortality laws applied to physical property.

Car riding craze in London.

London again discusses co-ordination.

Winners of bus maintenance awards announced.

Richey's review shows economic trends.

Conspectus of Indexes for October, 1930

Compiled for Publication in ELECTRIC RAILWAY JOURNAL by

ALBERT S. RICHEY

*The three index numbers marked with an asterisk are computed by Mr. Richey, as follows: Fares index is average street railway fare in all United States cities with a population of 50,000 or over except New York City, and weighted according to population. Street Railway Materials index is relative average price of materials (including fuel) used in street railway operation and maintenance, weighted according to average use of such materials. Wages index is relative average maximum hourly wage of motormen, conductors and operators on 136 of the largest street and interurban railways operated in the United States, weighted according to the number of such men employed on these roads.

BOOK REVIEWS

Development of Oil Circuit Breakers

"High Voltage Oil Circuit Breakers," by Roy Wilkins, consulting engineer Pacific Electric Manufacturing Company and E. A. Crellin, assistant engineer Pacific Gas & Electric Company, with an introduction by J. P. Jollyman. 301 pages, 119 illustrations. Published by the McGraw-Hill Book Company, New York, 1930. $4.

In this volume is given a complete history of the development of the high voltage oil circuit breaker, a discussion of the theory of its action, descriptions of modern forms, and an account of the results of many field tests.

Electrical Distribution

"Electrical Distribution Engineering," by Howard P. Seelye, Engineering Division, Detroit Edison Company. 710 pages, illustrated with 394 diagrams. McGraw-Hill Book Company, New York, 1930. $6.

This book is a comprehensive treatment of electrical distribution system design, including essentials of electrical and civil engineering and economics necessary to a knowledge of the subject. The principles are shown in their relation to the solution of practical problems. Many tables and data for reference are included.

A Technical Dictionary in Three Languages

Techno-Dictionary, English-German-Italian. 410 pages 4x6 in. Published by Hubert Hermanns, Berlin-Lichterfelde, Germany. $3.75.

For the readers of foreign technical periodicals the author has compiled this dictionary, which is a collection of technical terms for metallurgical, foundry, factory and workshop practice. There are three separate sections for the three languages translated. Following the word in the language of the section are given the definitions in the other two languages. No attempt is made to make this a general translation dictionary, but the author has endeavored to collect the largest possible number of terms as found in reading foreign technical periodicals and books. Approximately 4,000 to 5,000 words are translated from each of the three languages into the other two.

Mortality Laws Applied to Physical Property

"Life Expectancy of Physical Property Based on Mortality Laws," by Edwin B. Kurtz, head of department of electrical engineering State University of Iowa. Published by the Ronald Press Company, New York. 205 pages, 90 charts, 60 tables. $6.

While depreciation of physical property has, from time to time, been considered as a mathematical problem and formulas have been presented, it is seldom that the subject has been attacked from a scientific basis. In this book the author has applied to the life problems of physical property—structures, machinery, equipment, etc., the principles and methods which have been used by life insurance actuaries in dealing with the problems of human mortality. The author has collected an immense amount of material and has drawn off life experience of many engineering structures as a basis for determing a logical method of anticipating life of property.

Unified Public Control for London Transport Services

THE British transport minister, Herbert Morrison, has recently met in successive conference representatives of the various transport organizations serving London and suburbs including the London General Omnibus Company, the London Underground Railway, the Metropolitan Railway, the various municipal railway organizations, and the four main-line railroads of Britain. It is intended to proceed at once to open discussions following a study undertaken by Sir William McLintock, famous accountant.

Co-ordination of the undertakings engaged in passenger transport in the London district has been recommended in varying forms by successive commissions and committees, notably the London and Home Counties traffic committee in 1927. When he assumed office this subject formed one of Mr. Morrison's first preoccupations.

In a statement made in the House of Commons some time ago, he outlined the Government's ideas for dealing with the London traffic question. The sum and substance of Mr. Morrison's statement amounts to this:

No lasting solution will be found unless further steps are taken towards eliminating uneconomic and unnecessary competition. A far-reaching measure of unification under public control is essential. The object must be to bring about, so far as possible, a co-ordinated system of passenger transport so managed that earnings shall be sufficient to meet all proper charges, including reasonable remuneration of capital. The Government has concluded that the ends in view can be fully achieved and that the public interest can be fully safeguarded only if existing sectional financial interests are consolidated by the substitution of a single and simple form of public ownership. The Government will proceed to explore with all the interests concerned and with the assistance of an eminent chartered accountant, a plan for the complete consolidation on fair and equitable terms of the agencies now providing services by omnibuses, by tramways and by local railways. All the municipal interests should be included. While the Government has decided that the principle of public ownership should be applied, its aim will be to assert and effectively to provide for the principal of commercial management of a self-supporting consolidated transport system. In this way no liability need be entailed on public funds or public credit.

In planning the transfer of these transport services to public ownership the Government is not taking a leap in the dark. Already Parliament has recognized the necessity in many cases of entrusting essential national or local services to public bodies of this nature, such as the Port of London Authority, the Metropolitan Water Board, and the Central Electricity Board.

Mr. Morrison started with a bias in favor of a joint municipal body representative of the local authorities in the area, but in the end he concluded that this would be inappropriate. Further, his own experience of serving on local authorities showed him that there was too much "joint" and not enough "authority" about them.

The Government, therefore, aims at combining business-like management with public ownership by the creation of a small board consisting of persons of proved business capacity. Every effort will be made to secure the services of a chairman who combines business acumen and vigor with wide knowledge and experience, and who can be trusted to ensure that the appointment of officers of the board will be governed by considerations of efficiency. The board will be such as will command the confidence both of the investing public and of the users of transport in London. It will function as much as possible free from political interference so far as questions of management are concerned.

Mr. Morrison is anxious to utilize the experience and abilities which exist in the present undertakings, and it is likely that Lord Ashfield, charman of the London Underground combine, will be offered the chairmanship of the board.

The new authority's transport policy will be determined by technical fact and public interest. In this connection, it is interesting to note that, upon its advent to office, the present Government was successful in securing the rejection of the merger, under private control, of the Underground Railways, London General Omnibus Company, and the London County Council Tramways, which was on the point of receiving Parliamentary sanction.

The capital of the London traffic undertakings totals £113,052,023 ($565,260,115). The board will become responsible for services on which last year 4,000,000,000 journeys were made. The returns of passengers in 1929 in the Greater London area gave the following totals:

	Number	Per Cent
Tube railways.....	961,978,475	24.4
Street railways.....	1,076,250,997	27.3
Buses	1,912,092,980	48.3

The aggregate represented an increase of 51,195,852, compared with 1928. The London General Omnibus Company operates a fleet of 4,600 vehicles. It is closely linked with the London Underground combine.

No Material Changes Recommended for Liverpool

Fourteen months ago, Sir Henry Maybury was requested by the corporation to investigate and report upon traffic conditions in Liverpool with particular reference to the respective merits of street cars and buses. The most interesting of Sir Henry's conclusions is his vindication of the street railway system, which covers 167 miles and which he regards as "an excellent investment, capable of serving the Liverpool public extremely well for many years and of earning large sums of money for the rate-payers." Since the improvement of the cars has not kept pace with the maintenance of the track and with the demand for increased comfort and travel, Sir Henry suggests introduction of bogie cars capable of a much higher speed. In London, he declares, the maintenance of a higher standard of comfort and efficiency has enabled street railways to increase their traffic, and he predicts a similar result in Liverpool, if the rolling stock is modernized without delay. Sir Henry also says the cost of operating a well-organized and well-managed railway amid a considerable potential traveling population is probably lower per seat-mile than is the case with any other passenger vehicle, save perhaps the trolley bus. Nevertheless, he believes future needs should be met by augmenting the bus fleet. He is opposed to the construction of a subway system in Liverpool and sees no benefit from the suggestion for linking up the street railways with the Liverpool Overhead Railway.

A Remarkable Recovery at Glasgow

The statement of accounts of Glasgow Corporation Tramways for the year ended May 31 shows a wonderful improvement in finances. In former years this was a highly prosperous system, but for some time back it has recorded deficits owing to keen and growing bus competition. For the year ended May 31, 1929, there was a deficit of £85,222. This has now, for the twelve months ended May last, been changed to a surplus of £8,136. The deficit and surplus are arrived at after charging, in addition to working expenses, interest on capital, sinking fund, large allowances for renewals and depreciation, and other deductions.

It is to be noted that the last-mentioned allowances are about £70,000 less than those for the year before. Despite that, however, the traffic receipts are up £33,000. The improved revenue is largely attributed to the adoption of more comfortable cars equipped with more powerful motors giving higher car speed. The system generally has been tuned up. The city authorities have recently obtained powers to restrict unlimited bus competition, and if a bill which they now have before Parliament is passed, the municipality will obtain a monopoly of public passenger transport over tramway routes within the city. The corporation is also rapidly developing its own bus services.

New Light-Weight Cars Tested in Birmingham

Birmingham is experimenting with all three forms of transport. A few months ago, buses of the roomy, luxurious type, recently introduced in London, replaced a rail service, while in another district the trackless trolley has superseded the railway. Birmingham still has a strong street railway system under the control of the municipal corporation, the transport department of which is now testing out two new street cars of a lighter type than hitherto operated. By the use of duralumin and aluminum parts in construction a considerable reduction has been effected in the weight of the cars and operation has been cheapened. Transverse and reversible seating in leather and moquette is provided for 60 passengers.

London Catches the Car Riding Craze

The American freak cult of "tree-sitting" has a parallel in London, where travelers are car-riding for freak records. The craze has sprung up as a result of the popularity of the London County Council system's "shilling-all-day" tickets, which entitle the passenger to ride as often and wherever he wishes on any Council street car. The endurance record is at present held by James Kardux. With an all-day ticket he traveled 183½ miles in 21 hours 20 minutes. He rode in 57 street cars, starting at 5:20 a.m. and finishing late on the next day. His longest trip in one car was 30 miles. The ordinary fares would have totaled $2.87, whereas his shilling (24-cent) ticket defrayed the entire cost. Mr. Kardux broke a previous record of 175 miles.

PERSONAL MENTION

Messrs. Ingle and Moore Advanced in Jacksonville

Officials of Florida Company Advanced in Recognition of Their Long and Valuable Services. Mr. Ingle at Jacksonville Since 1922

JOHN P. INGLE, manager of the Jacksonville Traction Company, Jacksonville, Fla., has been made president of the company, and B. H. Moore, assistant treasurer, has been named treasurer. The new president will remain manager, and the company will follow its present operating policies. Mr. Ingle succeeded Donald C. Barnes, of Boston, as president. Mr. Moore's predecessor was Henry B. Sawyer, also of Boston. No other changes in the personnel of the company were made.

Mr. Ingle has been manager of the company since 1922, when he went to Jacksonville from Haverhill, Mass. Mr. Moore went to Jacksonville in March, 1928, from Boston, where he had been attached to the auditing division of Stone & Webster, Inc., operators of the Jacksonville railway system.

Every once in a while an editor finds that his work has been done for him by some one else. The occasions are infrequent, but such instances do occur. The present is one of them. If ever a man was bisected and dissected then John P. Ingle is so treated in the following accurate appraisal of the man, culled from a source not clearly identified but none the less accurate:

> Even the radical chaps who hate public service corporations as inventions of the devil designed solely to steal the rights of the people and directed by men who are two-thirds Machiavelli and one-third Mussolini admit that John P. Ingle is a regular fellow.
>
> Urbane and smiling always, whether in friendly intercourse or forensic tilt, he is as ready to plunge instantly into defense of a cause of a friend as he is to strike lusty blows in pushing his own battles. The sobriquet "happy warrior" might well be borrowed and fitted to this manager of the Jacksonville Traction Company.
>
> Few men in Jacksonville have engaged in such gusty controversies as John P. Ingle. None other has left behind so little personal bitterness and so few personal enemies.
>
> John P. Ingle has a genius for fighting hard and long for a cause, an issue or an ideal without letting the struggle descend to personalities. He manages to be charmingly inoffensive and friendly even when his carefully marshalled logic is destroying his opponent's case.
>
> Because of his limitless tact and his ability, he has the affectionate personal regard even of those who oppose in principle the interests he represents. This public impression of the man is only one facet of his character, but it reflects traits that appear again in other phases of his business activity.
>
> If you want to know about a man, ask his relatives or his employees. If you want to knew about John P. Ingle, ask the employees of the Jacksonville Traction Company. Ask in a friendly way, too, because there's a fair chance you'll find trouble if you act as though you don't like him. The answer to your question will warm the cockles of your heart with its enthusiastic, hearty man-affection for a regular fellow.

John Pierce Ingle was born in Salisbury, Md., in October, 1882. He spent his boyhood in Atlanta and attended the public schools of that city. Ambitious to study engineering, he entered the Georgia School of Technology and was graduated in 1906 as a bachelor of science in civil engineering.

On leaving school he at once became associated with Stone & Webster, Inc. His first major assignment was to the assistant superintendency of the Columbus Gas Company, Columbus, Ga.

His talents for making friends and solving difficult public utility problems soon won him recognition and he was promoted again, this time to the superintendency of the gas department of the Baton Rouge, La., Electric Company.

J. P. Ingle

His next step was to Keokuk, Iowa, as manager of the Keokuk Electric Company. Then he was transferred to Haverhill, Mass., as manager of the Haverhill Gas Light Company. In July, 1922, Mr. Ingle was sent to Jacksonville as manager. Just now the company of which he is the head is negotiating with the city for a new franchise.

J. S. Thorp in New Lackawanna Post

James S. Thorp, since September, 1928, electric traction engineer of the Delaware, Lackawanna & Western Railroad, has been appointed electrical engineer of that company. Previously he was assistant electrical engineer on the Illinois Central electrification. Mr. Thorp has had wide experience in steam and electric railway service. He has been connected with the electrification of the New Haven, the Norfolk & Western and the Victorian Railways of Australia. He was graduated from Virginia Polytechnic Institute in mechanical and electrical engineering, class of 1910.

Appointments Presage Intensive Traffic Development

Announcement of the appointment of E. B. Smith as general freight and passenger agent, and W. R. Hickrod as superintendent of transportation, and the placing in effect of new schedule in the interest of improved freight transportation has been made by E. L. Moore, general superintendent of the Evansville & Ohio Valley Railway, operating railway and bus lines at Evansville, Ind.

Mr. Smith assumes the post of general freight and passenger agent after four years with the Chicago & Eastern Illinois Railroad freight department. A native of Evansville, he was formerly with Servel, Inc., traffic department, and as road representative of the Fisk Tire & Rubber company.

Mr. Hickrod, has spent the greater part of his business years in Evansville & Ohio Valley service. Starting in as conductor in 1905, he served in this capacity for eight years. Up to his most recent promotion to superintendent of transportation, he had operated the dispatcher's office since 1913.

The company has established freight pick-up trucking service between Evansville and Mount Vernon, Ind., insuring daily deliveries of merchandise. Orders will be received from merchants in Mount Vernon for merchandise from Evansville supply centers, and store door deliveries will be made, Mr. Moore stated.

Store door freight delivery service has also been started between Evansville and Rockport. Orders for merchandise will be received by the agent at that point. Package express convenience is now available on all cars and buses in both directions at moderate transportation rates.

E. J. Booth Is Made Assistant to President

Edwin J. Booth has been elected assistant to the president of the Chicago, South Shore & South Bend Railroad, South Bend, Ind., according to announcement by Robert M. Feustel, president. Mr. Booth has also been elected assistant to the executive vice-president of the Midland United Company, of which he also is comptroller.

J. H. Pritchard Manager at Lynchburg

J. H. Pritchard, of Chicago, has been appointed manager of Lynchburg Traction & Light Company, Lynchburg, Va., to succeed C. D. Thomas, resigned. Mr. Pritchard will arrive in Lynchburg about Nov. 1. He is a native of eastern Virginia and a graduate of Virginia Polytechnic Institute, where he majored in engineering. He is working at present in the headquarters office of the Central Public Service Company in Chicago which controls the Lynchburg property. At one time he was an engineer for a utility company in St. Joseph, Mo.

Mr. Thomas was manager of Lynchburg Traction & Light Company a little more than one year, taking the place of D. C. Frost at the time of the latter's death. He was assistant to Mr. Frost for several months before being appointed manager.

G. M. Dahl Now Factor in Interborough Affairs

ELECTION of Gerhard M. Dahl, chairman of the Brooklyn-Manhattan Transit Corporation, as chairman of the board and of the executive committee of the Interborough Rapid Transit Company, took place early last month. In effect, it makes Mr. Dahl the dominant figure in the city's transit affairs. In addition to

G. M. Dahl

his positions in B.-M. T. and I. R. T., Mr. Dahl also is chairman of the Brooklyn & Queens Transit Corporation, controlled by the B.-M. T., and also heads the Brooklyn Bus Corporation, bus operating subsidiary of the B. & Q. T.

As representative of the Interborough, appointed by the directorate, Mr. Dahl will take part in unification conferences with the city transit authorities. As head of the B.-M. T., he already controls the destinies of that company in unification. For several months Mayor Walker's transit advisers have been discussing a basis for fixing a price to be offered the B.-M.T.

Mr. Dahl and Samuel Untermyer, special counsel for the city in transit matters, already have discussed possibility of forming a quasi-public holding company to take over securities of the two independent companies and operate a unified system, including the city's new lines, scheduled to be ready in the fall of 1931.

Appointment of Mr. Dahl to represent the Interborough in unification discussions also was regarded as a significant development. As the *Wall Street Journal* has pointed out, Interborough management, up to this time, has refused consistently to take part in unification negotiations on the grounds that it could not until its increased fare suits were acted on finally by the courts.

The make-up of the Interborough executive committee indicates the strength of the Dahl group in the company's affairs. On the committee, in addition to Mr. Dahl, are Charles Hayden and Albert H. Wiggin, both of whom were members of the protective committee, formed last March to bring the Interborough into the unification picture. Both Mr. Hayden and Mr. Wiggin also are on the B.-M. T. directorate. Other members of the committee favor unification.

It also is interesting to note that four members of the Interborough executive committee are directors of the Chase National Bank. Frank L. Folk, who is a voting trustee of the Interborough, with Mr. Dahl and Frank Hedley, is also a director of the bank.

Mr. Dahl has had an unusual record of achievement as a lawyer, as an executive and as a financier.

Memorial Fountain for Late M. L. Harry

Formal dedication of the M. L. Harry memorial fountain at Decatur, Ill., was made on Sept. 6. The fountain was a gift to the city by a group of friends of the late M. L. Harry, who felt that the memory of a man who had meant so much to the community in which he lived deserved to be preserved by some tangible token. To present this worthy memorial, this group of friends selected L. E. Fischer, vice-president in charge of operations of North American Light & Power Company, a life-long friend of Mr. Harry's. In a brief impressive presentation talk, Mr. Fischer paid a just tribute to Mr. Harry and explained in behalf of those who made this monument possible, the occasion for the ceremony.

M. L. Harry lived in Decatur for a quarter of a century. His death, as the result of an unfortunate accident, occurred on Oct. 11, 1929, while he was on duty for the Illinois Power & Light Corporation by which he was employed, and in the service of humanity that he loved so much.

Messrs. Burns, Plummer and Brown in New Dallas Posts

W. R. Burns

W. R. BURNS, who has been assistant general manager of the Dallas Railway & Terminal Company, Dallas, Tex., for several years, has been elected vice-president and appointed general manager of the company. He succeeds the late Richard Meriwether. Other appointments announced include that of George I. Plummer and B. R. Brown as assistant general managers in charge of traffic and engineering and construction, respectively. A statement by President John W. Carpenter of the company, in which he eulogized the work of the men who are advanced, says:

B. R. Brown

The company takes pride in being able to fill the top positions in the organization with men who have developed from the ranks. This has been the policy pursued for several years and it has built a spirit of loyalty that has made the local railway system efficient despite decreased patronage and lowered income. This policy will continue and there will always be opportunity for present and future young men employees. This will insure good service to Dallas patrons. In the final analysis, this is what the people are entitled to and which we strive to supply.

Mr. Burns has been closely connected with the operations of the company for

G. I. Plummer

many years. His experience with the company and his previous public service work fit him admirably to be general manager. He has an intimate knowledge of the operating history of the company and has made a close study of its problems. He started in the offices of the Dallas company fifteen years ago as clerk in the accounting department. Several years later he was made assistant secretary-treasurer and subsequently was made assistant general manager. Mr. Burns was born on a farm in Cooke County, near Gainesville. He went to East Texas State Teachers' College at Commerce after he finished at the Cooke County schools.

Mr. Plummer has been with the Dallas

Digitized by Google

company for 24 years. His first job was at the carhouse. He has worked all through the ranks in the traffic department and has seen the Dallas system grow from belt lines to one of the most efficient systems in the country.

Mr. Brown entered the engineering department of the company 21 years ago and has directed construction work on many of the present lines. He has been in charge of the track and line department for many years.

C. D. Emmons, New Hudson & Manhattan Head, Is Honored

One hundred and fifty business executives prominently identified with transportation and associated industries, honored Charles D. Emmons, recently elected president of the Hudson & Manhattan Railroad, operating between New York and New

C. D. Emmons

Jersey under the Hudson River, at a testimonial dinner tendered him on Thursday evening, Oct. 16, at the Lotos Club, New York.

Arthur Brisbane, well known journalist, who contributes the department "Today" to the Hearst papers, was the principal speaker. Others who spoke included Matthew C. Brush, J. H. Hanna, president, Capitol Traction Company, Washington, D. C., and Charles J. Hardy, general counsel, American Car & Foundry Company. Charles C. Castle, vice-president of the American Car & Foundry Company, was toastmaster.

The committee in charge of arrangements for the dinner included: George Le Boutillier, vice-president Pennsylvania Railroad; Matthew C. Brush, president International Corporation; Charles R. Ellicott, vice-president Westinghouse Air Brake Company; Frank Hedley, president Interborough Rapid Transit Company; Frederick Green, Triplex Safety Glass Company; H. Hobart Porter, director B.-M.T. and Hudson & Manhattan Railroad; Charles F. Scott, General Electric Company; Lucius S. Storrs, president United Railways & Electric Company of Baltimore, and William H. Woodin, president American Car & Foundry Company.

Among those who attended the dinner were:

H. H. Vreeland, I.R.T.; W. S. Menden, Brooklyn-Manhattan Transit Corporation; G. W. Jones, Brooklyn-Queens Transit Corporation; W. T. Rossell, Brooklyn-Queens Transit Corporation; F. T. Wood, Fifth Avenue Coach Company; L. H. Palmer, Fifth Avenue Coach Company; H. B. Potter, United Railways & Electric Company, Baltimore; Guy C. Hecker, American Electric Railway Association.

J. V. Davies, Hudson & Manhattan Railroad; C. E. Morgan, Cincinnati Car Corporation; E. C. Faber, of Barron G. Collier Company; F. H. Shepard, Westinghouse Electric & Manufacturing Company; T. R. Langan, Westinghouse Electric & Manufacturing Company; W. M. Wampler, Ellcon Company; E. B. Smith, American Brake Shoe & Foundry Company; T. W. Casey, National Pneumatic Company; C. S. Hawley, Consolidated Car Heating Company; S. J. Cotsworth, Lorain Steel Company; C. B. Keyes, General Electric Company; J. G. Barry, General Electric Company; C. A. Melvin, Griffin Wheel Company; C. S. Klumpp, Hudson & Manhattan Railroad; T. A. Kenney, Allied Engineers, Inc.; C. B. Buchanan; R. P. Stevens; W. J. Stanton; H. B. Flowers; W. A. Lake, Pantasote Company; Ross Hayes, of Adams & Westlake Company; Adrian Hughes, Jr., United Railways & Electric Company, Baltimore; E. P. Waller, General Electric Company; J. A. Queeney, Philadelphia Rapid Transit Company; J. A. Miller, Jr., Electric Railway Journal; W. G. Gove, Brooklyn-Queens Transit Corporation.

Mr. Emmons, guest of honor, was born in Lafayette, Ind. He was graduated from the University of Pittsburgh in 1892 with the degree of civil engineer. For nine years he was connected with the maintenance of way and signal departments of the Pennsylvania Railroad. During the past 30 years he has been actively associated with the development of transportation in several large American cities, serving as president of the Boston & Worcester Street Railway; president of the Boston Elevated Railway and president of the United Railway & Electric Company, Baltimore. He became president of the Hudson & Manhattan Railroad on Oct. 1, 1930, upon the retirement of Oren Root.

A. E. Reynolds Now at St. John

A. E. Reynolds, for eight years vice-president and general manager of the Springfield Gas & Electric Company and the Springfield Traction Company, Springfield, Mo., has been transferred to St. John, New Brunswick, as vice-president and general manager of the New Brunswick Power Company. The St. John Company and the Springfield Companies are subsidiaries of the Federal Light & Traction Company, New York, of which E. N. Sanderson is president.

Mr. Reynolds entered public utility work in Plattsburgh, N. Y., finally being appointed manager of the Plattsburgh Traction Company. After the purchase of this road by the Delaware & Hudson Company, Mr. Reynolds was transferred to Glens Falls, N. Y., as resident manager of the Hudson Valley Railway. He remained in Glens Falls eight years and was then elected general manager of the United Traction Company, serving the capital district, with office in Albany. He resigned this position in 1922 to become associated with the Federal Light & Traction Company and was immediately sent to Springfield, Mo.

Mr. Reynolds has been highly honored in the electric railway and public utility field in Missouri, being past-president of the Mid-West Electric Railway Association and past-president of the Missouri Association of Public Utilities. In Springfield, Mr. Reynolds was connected with many civic clubs and organizations.

Mr. and Mrs. Reynolds left Springfield the middle of October for St. John.

T. E. Thomas Runs London's Municipal Trams

T. E. Thomas, traffic manager in the London County Council Tramways Department, was recently appointed general manager of the undertaking succeeding J. K. Bruce, who retired on June 30. Mr. Thomas, is 48 years of age. He entered the Council's service in 1917, being selected from 38 candidates who applied in response to public advertisements for the position of development superintendent in the traffic branch of the tramways. In 1925 he was appointed traffic manager. Mr. Thomas commenced his tramway career in 1899, when he entered the service of the London United Tramways, Ltd., under the late Sir Clifton Robinson. He was appointed district engineer of the Surrey lines of that company in 1910, and later transferred to the staff of the Underground Group of companies. He became commercial superintendent of that group of companies after the absorption of the London General Omnibus Company. He was awarded the gold medal of the Institute of Transport in 1927, and has been a member of the Council of the Tramways, Light Railways, and

T. E. Thomas

Transport Association since 1927. On taking the post he said it would be his constant endeavor to justify the confidence which had been reposed in him.

A. E. Francis Promoted in San Francisco

A. E. Francis, since 1928 superintendent of ferry terminals for the Market Street Railway, San Francisco, Cal., has been named superintendent of the company's Geneva division, succeeding the late Byron F. Dunn. The division is one of the largest of the system, operating lines in the Mission and Ingleside districts and the San Mateo interurban cars. Mr. Francis began his career as a conductor 27 years ago in the Potrero district. Later he became a motorman and then an inspector, a position he held until his appointment as superintendent of ferry terminals. His successor in that position is G. W. Evington, who has been an inspector since 1915. He formerly was a conductor, also.

✦

Earl F. Theisinger has been made associate editor of *Bus Transportation*, a McGraw-Hill publications. He joined the staff in 1925, writing for departments devoted to maintenance, and shop practices and methods. In 1927 he was made an assistant editor.

Digitized by Google

H. F. Dicke, Lehigh Official, Heads Pennsylvanians

Henry F. Dicke, vice-president in charge of operation of the Lehigh Valley Transit Company, Allentown, Pa., since 1926, has been elected president of the Pennsylvania

H. F. Dicke

Street Railway Association. For eight years before joining the Allentown company in 1925 as assistant to the president, Mr. Dicke was general manager of the Utah Light & Traction Company, Salt Lake City, Utah. At the time he went to Allentown from Salt Lake City, Mr. Dicke also was made vice-president of the East Penn Electric Company, Pottsville, and vice-president of the Williamsport Passenger Railway.

Mr. Dicke is a native of Fort Wayne, Ind. In 1899 he entered the service of the Fort Wayne Traction Company in the accounting department, where he served for a period of five years. He resigned that position to become general auditor of the Ohio & Indiana Construction Company. This company was formed to build a 65-mile line from Fort Wayne to Lima, Ohio. During this construction work Mr. Dicke devoted some time to the engineering department and became superintendent of construction. When the work was completed he was placed in charge of operation of the property owned by the Fort Wayne, Van Wert & Lima Traction Company, which later, with several other properties, merged with the Ohio Electric Railway.

For seven years he had charge of operation of the northern division of the Ohio Electric Railway, consisting of 242 miles of interurban lines, and then resigned to go to Boise, Idaho, as general manager of the Boise Valley Traction Company. He served in this capacity for five years, and was then made general manager of the Utah Light & Traction Company at Salt Lake City, which position he relinquished to take up his duties with the Pennsylvania companies.

L. B. Herrington Heads Union Transfer

L. B. Herrington, president of the Kentucky Traction & Terminal Company, the Kentucky Utilities Company, Louisville, Ky., and subsidiary companies, including the Consolidated Coach Corporation, which was taken over a few months ago, has also been made president of the Union Transfer Company, Nashville, Tenn., controlling interest in the Union Company having been purchased by the Insull interests, for Consolidated Coach Corporation, which operates in Kentucky and Tennessee. Still more recently Consolidated Coach has bought into the Alabama Bus Company and the Capital Coaches, Inc., giving Consolidated 5,000 miles of route and 350 buses.

The Union Transfer Company maintains general offices at Nashville. It operates buses between Nashville and Birmingham, Ala.; Nashville and Hopkinsville, Ky.; Nashville and Knoxville; Nashville and Chattanooga; and Nashville and Florence, Ala., with numerous feeder lines. The Consolidated has gradually linked up practically all of the worthwhile lines in Kentucky, and has been gradually adding to its Tennessee holdings. The Insull interests also hold a considerable amount of stock in the Old Dominion lines and others.

Other than Mr. Herrington, new officers of Union are about the same as for Consolidated. C. R. Quarles, treasurer and general manager of Union, became a member of the board, and assistant secretary-treasurer. J. P. Pope, vice-president of the Kentucky Traction & Terminal Company, and Guy A. Huguelet, Lexington, Ky., are vice-presidents of both companies; A. A. Tuttle, Louisville, secretary-treasurer both companies; L. W. Haley, P. Pherigo and G. C. Jones, all of Lexington, assistant treasurers.

Frank H. Miller on Louisville Executive Committee

Frank H. Miller, vice-president and general manager of the Louisville Railway, Louisville, Ky., on Oct. 15, was elected a director of the company, and a member of the executive committee, succeeding John W. Barr, Jr., who resigned several months ago.

Messrs. Fleming and Weber in New Offices in Chicago

H. B. Fleming

AS NOTED briefly in ELECTRIC RAILWAY JOURNAL for October, the Chicago City Railway, the Calumet & South Chicago Railway, and the Southern Street Railway have elected Harvey B. Fleming president and chairman of the board of directors, succeeding the late Leonard A. Busby. To succeed Mr. Fleming in the position of vice-president of the south side companies, Harry P. Weber, Mr. Busby's law partner, has been chosen vice-president and general counsel.

Mr. Fleming also has been elected a member of the board of operation of the Chicago Surface Lines, a member of the executive committee of that board and of the Chicago City & Connecting Railways collateral trust committee.

Ever since he was placed in charge of tracks, buildings and electrical work for the Chicago City Railway Company in 1899 Mr. Fleming has been associated with city railway operation in Chicago. He was educated in the public schools of Newburgh, N. Y., Newburgh Academy, and Washington University, St. Louis, Mo., from which latter institution he received the degrees of bachelor of science and civil engineer. He is a member of the Sigma Alpha Epsilon fraternity.

Prior to the completion of his education, Mr. Fleming was employed by the T. M. Marvel Company, shipbuilders in Newburgh, and after he was graduated from Washington University, he was appointed assistant engineer of the St. Louis Water Works Department. His first street railway experience was as engineer for the National Street Railway Lines, of St. Louis.

He became chief engineer of the Chicago City Railway in 1905, and since that time has served in various capacities, being elected director and vice-president of the Chicago City Railway in 1912 and appointed chief engineer of the Chicago Surface Lines in 1914 when the surface railways of Chicago were unified and the Surface Lines organization was created. He has been a member of the board of supervising engineers ever since that board was created by ordinance in 1907, representing the so-called South Side lines.

H. P. Weber

Mr. Fleming is also president and chairman of the board of directors of the Hammond, Whiting & East Chicago Railway and the Chicago & Western Railway.

Melvin A. Traylor, president of the First National Bank; James Winston and Harry P. Weber have been elected directors to fill vacancies caused by the deaths of Frank O. Wetmore and Leonard A. Busby and by the resignation of Frank W. Thomas.

Redistribution of Duties on Indiana Railroad

HENRY BUCHER, vice-president and general manager of the Indiana Railroad, has announced the appointment of three new trainmasters with responsibilities that supersede the duties of division superintendents, which titles have been abolished. The trainmasters will report to C. C. Lentz, superintendent of transportation.

Arthur Hartgrove, formerly superintendent of the Tipton division of the Union Traction Company, has been made trainmaster in charge of interurban operations on lines between Indianapolis, Muncie and Bluffton, and between Indianapolis, Newcastle and Muncie, succeeding A. R. Manifold, former division superintendent. His headquarters will be at Muncie.

N. K. Smith, formerly division superintendent of the Fort Wayne-Lima Railroad, Fort Wayne, Ind., is appointed trainmaster with supervision over interurban operations between Indianapolis and Peru (Tipton division), Anderson and Marion, and Tipton and Alexandria. Mr. Smith's headquarters will be at Kokomo.

M. F. Strahan will be trainmaster at Indianapolis in charge of interurban operations on all lines between the Indianapolis terminal and immediate suburban territory. He will also have supervision over the Indiana Railroad's interurban buses, connecting Indianapolis, Anderson and Marion.

Mr. Bucher also named two new superintendents of city lines, who will report to J. A. Greenland, general superintendent of transportation—city lines.

C. J. Stanley, with headquarters at Anderson, will have charge of all city street car and bus operations in Anderson and Muncie.

S. R. Humbert, with headquarters at Kokomo, will have charge of city operations in Marion and also of local cars and buses of the Northern Indiana Power Company in Kokomo. The Northern Indiana Power Company's transportation lines are operated under the same co-ordinated management as the Indiana Railroad. E. K. Grimes, formerly superintendent of the Marion city lines, has been transferred to the transportation department at Indianapolis.

Glenn H. Shaw Heads Safety Council's Railway Section

Glenn H. Shaw, personnel and safety director, Akron division, Ohio Edison Company, was elected general chairman of the electric railway section of the National Safety Council, at the recent meeting in Pittsburgh, to succeed Melvin W. Bridges. To his work as a safety director Mr. Shaw brings a background of practical experience as an operator, earnestness of purpose and enthusiasm for his subject. His work with the Ohio Edison Company has contributed in no small measure to the success of that company in combating the accident menace.

In January, 1920, Mr. Shaw went to work for the Cleveland Railway as trainman. A few months later he was singled out for promotion to the position of traffic inspector, and shortly thereafter was made a safety inspector in the company's newly organized accident prevention department. He continued in this capacity until December, 1922, when he went with the Northern Ohio Power & Light Company, Akron division, as personnel and safety director, continuing in this position when the company was recently reorganized as the Ohio Edison Company.

Born on Feb. 8, 1885, at West Almond, Alleghany County, N. Y., Mr. Shaw attended grade schools near the place of his birth, and later completed a course at Wilson Academy, Angelica, N. Y. He entered the service of the Schenectady Railway as conductor in 1906 where he remained until 1910, when he took a position as trainman with the Albany Southern Railroad, a high-speed third rail system between Albany and Hudson, N. Y.

H. F. Merker in Construction Work in St. Louis

H. F. Merker, as president of Merker & Company, St. Louis, Mo., is now engaged in carrying out two large construction contracts in that city. One has to do with the work of preparing the old terminal of the Illinois Traction System at Twelfth and Lucas Avenue for the St. Louis Electric Terminal Railway. The other has to do with the preparation of the site at High, Twelfth, Franklin and Wash Streets for the *Globe-Democrat's* new building. The building contractor in each instance is the Fruin-Colnon Company.

H. F. Merker

Mr. Merker is indirectly associated with the Illinois Power & Light Corporation and the Missouri Rolling Mills Company. It was from the Missouri Rolling Mills Company that he went to Brooklyn in 1923 as engineer of maintenance of way and structures of the Brooklyn surface system. From 1905 to 1919 he was engineer of maintenance of way of the East St. Louis & Suburban Railway. He has been active as an engineer since his graduation from the University of Illinois in 1898.

Activities of W. H. Sawyer Widened

Willits H. Sawyer, formerly president of Stevens & Wood, Inc., has moved his office as executive engineer to 120 Broadway, New York City, where he will also be associated with R. P. Stevens & Company, Inc. In addition to his consulting activities in connection with the management problems of public utilities, Mr. Sawyer will give an appreciable part of his time to the duties required by his recent appointment as co-receiver of the Atlantic Public Service Associates, Inc. He will also continue as receiver for the Springfield Railway, Springfield, Ohio.

Frank Couzens and S. D. Waldon on Detroit Board

Frank Couzens, dismissed by former Mayor Bowles, has been reappointed by Mayor Murphy, of Detroit, Mich., to a place on the Street Railway Commission. He fills the vacancy made by the resignation of Frank Dohaney, appointed by Mr. Bowles. It is understood that Commissioner Couzens will become practically directing head of the system of the Department of Street Railways. He is to have his office in the railway administration building and will devote much of his time to the direction of the department. The post brings no remuneration.

Mr. Couzens is a son of former Mayor James Couzens under whose régime as Mayor of Detroit the municipal system was founded. He was first appointed to the commission in 1929 by John Lodge, then Mayor, but was dismissed by Mayor Bowles last April presumably because he refused to see eye-to-eye with the then Mayor on municipal railway problems.

Charles W. Burton has also resigned from the commission. He has been replaced by Sidney D. Waldon, president of the Rapid Transit Commission. Mr. Burton was appointed to the commission by Mr. Bowles after the recall election of July 22.

Mr. Waldon will continue to act as a member of the Rapid Transit Commission. Mr. Waldon was on the Detroit Street Railway Commission for one year, in 1919, before he became a member of the Rapid Transit Commission.

Mayor Murphy was disposed to merge the two commissions, but Mr. Waldon pointed out that the powers of the two commissions are dissimilar. The Legislature can repeal the rapid transit act, but it cannot amend the charter of Detroit. The work of the two commissions will now be more closely co-ordinated, but the two bodies will retain their separate powers.

English Publisher Visits United States

Among the delegates to the International Roads Congress, held recently in Washington, D. C., is Horace Wyatt, director *Motor Transport* and *Bus and Coach*, published in London. Mr. Wyatt has since made the tour of cities proposed for the delegates, and now intends to visit in New York, Cleveland, Boston, Toledo, Toronto, Montreal and other cities to study the operation of both buses and trucks. He arrived in the United States on Oct. 6 and will leave for home from Quebec on Nov. 14.

✦

B. A. Hinkley, formerly chief inspector, has been promoted to acting superintendent of the Springfield Traction Company, Springfield, Mo., to fill

Digitized by Google

the vacancy caused by the death on Sept. 10 of Charles A. Coons, assistant general manager. Mr. Hinkley started his career with the Springfield system in 1904 as a motorman. He was made chief inspector four years ago.

✦

John E. Davis has resigned as manager of the public relations-public information department of the Kentucky Utilities Company, Louisville, Ky., to take charge of the public utilities promotion work of the Whitney-Graham Company, Buffalo, N. Y. Mr. Davis has had charge of advertising and publicity for the company since Oct. 15, 1924, and has been director of public relations for the last two and one-half years.

✦

John A. Seymour, auditor, has been elected president of the Chicago Rapid Transit Company, Section No. 6, A.E.R.A., for the ensuing year. Mr. Seymour succeeds George E. Tebbetts, engineer of structures, who had served in this capacity since last October.

✦

Charles J. McMorrow, supervisor of service for the Springfield Street Railway, Springfield, Mass., for the last ten years and for 24 years an employee of the company, has resigned to become sales manager for a real estate company in Springfield.

✦

William F. Allen, advertising manager for the St. Louis Public Service Company, St. Louis, Mo., has been appointed to the publicity committee of the ninth annual community fund campaign scheduled for Nov. 10 to 20. He will have charge of public utilities advertising.

✦

Robert H. Mangum, formerly assistant manager of the investment department, has been named manager of the publicity department of the Alabama Power Company. He succeeds W. J. Baldwin, who has been appointed publicity manager for the Commonwealth & Southern Corporation. Mr. Mangum has been connected with the power company since 1927.

✦

R. A. Stephen, formerly assistant treasurer of the Commonwealth & Southern Corporation, has been elected treasurer. B. W. Eggert and F. A. Bain have been elected assistant treasurers.

✦

Harvey C. Couch, president of the Louisiana Power & Light Company, New Orleans, La., and an officer of other companies included in Electric Power & Light Company group, has been elected a director of the St. Louis-San Francisco Railway, filling the vacancy caused by the resignation of Leonard Adkins. Mr. Couch has also been appointed a member of the executive committee, succeeding Eugene V. R. Thayer, resigned.

✦

Fred L. Markham, sales manager American Car Company, St. Louis, resigned his position with the Brill organization on Oct. 1.

✦

Charles S. Kimball, past president of the American Electric Railway Engineering Association and at present connected with the Portland Cement Association, has been appointed chairman of the committee of the Washington Society of Engineers which is to investigate the drainage and surfacing of air ports.

OBITUARY

E. W. Bemis

Edward Webster Bemis, economist and public utilities expert, died on Sept. 25 in Springfield, Mo. Mr. Bemis suffered a general breakdown last winter.

From 1901 to 1909 Mr. Bemis was superintendent of the Water Department at Cleveland, Ohio. He went to New York in January, 1910, as deputy commissioner of water supply, gas and electricity, holding that position until October. Since then he had been a consulting engineer for cities, states and public utility bodies. From 1913 to 1923 he was a member of the advisory board of the valuation bureau, Interstate Commerce Commission. Mr. Bemis wrote extensively on public utility topics.

Mr. Bemis was born in Springfield, Mass., on April 7, 1860, and was graduated from Amherst College in 1880, receiving his A.M. degree there four years later. Johns Hopkins University conferred the Ph.D. degree upon him in 1885. From 1889 to 1892 he was professor of history and political economy at Vanderbilt University. For the next three years he was associate professor of political economy at the University of Chicago. He became assistant statistician of the Illinois Bureau of Labor Statistics in 1896, and from 1897 to 1899 was Professor of Economics and History at the Kansas State Agricultural College.

✦

P. Van Burington

Philander Van Burington, former secretary and treasurer of the Columbus Railway, Power & Light Company, Columbus, Ohio, died on Oct. 8. Mr. Burington retired five years ago after an association of 34 years with the Columbus utility. He was at one time auditor and fiscal agent. Before becoming associated with the Columbus company, Mr. Burington was general freight agent for the old Scioto Valley Railroad, now a part of the Norfolk & Western Railroad. He was 83 years of age.

✦

Charles A. Coons

Charles A. Coons, assistant general manager of Springfield Traction Company, Springfield, Mo., who died on Sept. 10, had long been engaged in electric railway work. For 25 years he was superintendent of the International Railway, Buffalo, N. Y., and for 13 years was general superintendent of the United Traction Company at Albany, N. Y. He was born in Watertown, N. Y., in 1867. He went to Springfield to assume the duties of assistant general manager of the company there in the early part of 1928.

✦

W. W. Arnheim

William Walter Arnheim, president of Marks Arnheim, Inc., men's clothiers, of New York, died suddenly on Oct. 5 of heart disease at his country home at Elberon, N. J.

Mr. Arnheim was not an operating street railway official, but he was a pioneer in the movement for traffic reform. He was one of the first to recognize the extreme seriousness of New York's traffic problem, and with unflagging enthusiasm, combined with the knowledge of an expert, he set out to find a solution. It must have been a source of much satisfaction to him to have witnessed, long before his untimely end, the practical operation of some of the reforms he so long and consistently advocated. Electric Railway Journal differed with Mr. Arnheim on some of the things he suggested, but it respected the man for his zeal.

Mr. Arnheim was born in Cincinnati 49 years ago. He served on the Mayor's committee of plan and survey and as chairman of the traffic committee of the Broadway Association, and had written many articles on New York's traffic problems, for which he from time to time, offered his own solutions.

✦

P. J. Pringle

P. J. Pringle, chief engineer and general manager of the Electric Supply Company of Victoria, Ltd., Australia, died recently at Zurich, Switzerland, while he was proceeding on a holiday visit to England. He formerly occupied various important positions in electrical engineering and consulting work. His last appointment in England was that of borough electrical engineer and tramway manager at Burton-on-Trent.

✦

W. H. Harton

William H. Harton, 57 years of age, general manager of the Cincinnati, Newport & Covington Railway, died on Sept. 16 at Fort Mitchell, near Covington, Ky. Mr. Harton started with the company 38 years ago as an engineer, becoming general manager following the death of James P. Ernst. He was president of the Kentucky Association of Public Utilities, in 1924; and was re-elected to the post at a meeting in Louisville in January, 1929. There was no meeting of the association in 1930. Mr. Harton was well known throughout Kentucky and in Southern Ohio among utility operators.

✦

G. S. Amidon

George S. Amidon, an employee of the United Electric Railways, Providence, R. I., for 44 years, died on Oct. 8. During his service he had been superintendent of the Riverside, Olneyville and East Providence divisions. At the time of his death he was employed at the North Main street carhouse. He entered the employ of the railway at the age of 21, as a conductor, and was successively starter, inspector and superintendent. Mr. Amidon was born in Springfield, Mass., 66 years ago.

✦

William B. Cutter, one of the organizers of the Buffalo-Depew Railway, now part of the interurban lines of the International Railway, Buffalo, N. Y., is dead. He was born in Buffalo on Dec. 14, 1853, and was a pioneer in the development of real estate in the suburban districts adjacent to Buffalo. The railway was organized in 1898. About ten years ago Mr. Cutter retired from active business.

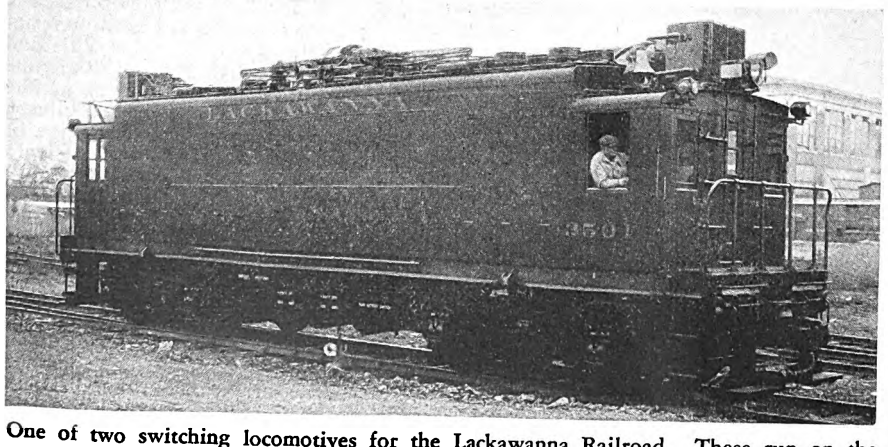
Lackawanna Railroad Gets Switching Locomotive

In connection with the suburban electrification out of Hoboken, the Delaware, Lackawanna & Western Railroad some time ago ordered two electric locomotives. These are for transfer service between the Jersey City yards and the Secaucus and Harrison yards and also for switching in these yards. The first of the locomotives was recently shipped from the Erie Works of the General Electric Company. These locomotives are of the "three-power" type, capable of operating from the 3,000-volt trolley, from an oil engine or from a storage battery.

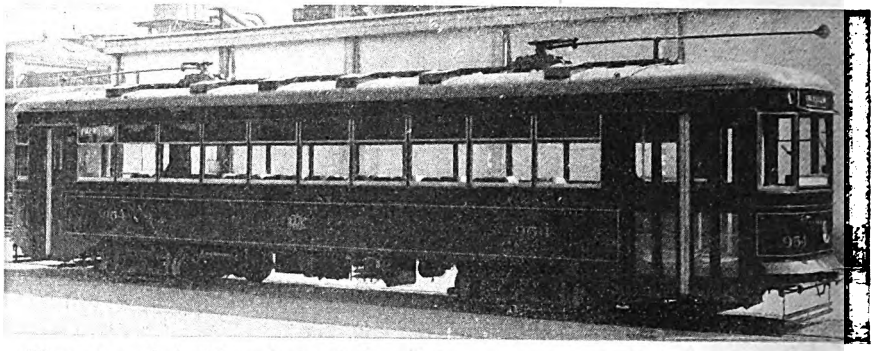
The locomotive is of the double-truck box-cab type with four direct geared, direct current box frame series motors, designed to run two in series on 3,000 volts. A 300-hp. Ingersoll-Rand oil engine, direct connected to a 750-volt d.c. generator furnishes an auxiliary source of power. There is also a storage battery of 360 Type MVA-21 Exide ironclad cells.

In the electric zone the motors operate continuously from the 3,000-volt d.c. trolley. Outside the electric zone the engine-generator set charges the storage battery and supplies power to the traction motors. Current is furnished to the motors at 600 to 700 volts. At light loads the excess power of the engine charges the battery; at loads above 300 hp. the battery discharges and relieves the engine from overload. Auxiliaries operate from the storage battery. Increased tractive effort at the higher speeds is obtained on internal power by shunting approximately 50 per cent of the field current through a non-inductive resistance. The single unit Type PCL control is non-automatic. By means of contactors and transfer relays, the trolley and battery circuits are interlocked so that traction motors can be energized from only one of these sources at a time.

The total weight of the locomotive, with fuel, water and sand, is 124 tons, and the maximum tractive effort at starting is 60,000 lb. The maximum permissible speed is 40 m.p.h. Length inside knuckles is 47 ft. 10 in. Locomotive, in running order, weighs 248,000 lb.; all weight is on driving axles.



One of two switching locomotives for the Lackawanna Railroad. These run on the 3,000-volt overhead, storage battery or on oil-electric power



New type of double-end car delivered for service on the Lehigh Valley Transit

New Cars Placed in Service by Lehigh Valley Transit

Ten new cars have been recently delivered by J. G. Brill to the Lehigh Valley Transit Company, of Allentown, Pa., for service on the Allentown-Bethlehem loop. Many changes with respect to the old type of equipment have been incorporated in these cars. They are lighter, weighing 37,320 as compared with 42,000 lb., and attain a higher speed. Acceleration can be controlled by either hand or foot operation New types of springs and shock absorbers have made possible low body lines. Total seating capacity of each car is 48 passengers. Detailed specifications as follows:

Name of railway	Lehigh Valley Transit Company, Allentown, Pa.
Number of units	10
Type of unit	Two-man, motor, passenger, city, double end, double truck
Number of seats	48
Builder of car body	J. G. Brill Co., Philadelphia, Pa.
Date of order	March 26, 1930
Date of delivery	Oct. 2, 1930
Weights:	
Car body	17,920 lb.
Trucks	9,900 lb.
Equipment	9,500 lb.
Total	37,320 lb.
Bolster centers	22 ft. 5 in.
Length over all	45 ft. 10 in.
Length over body posts	32 ft. 5 in.
Truck wheelbase	5 ft. 4 in.
Width over all	8 ft. 4 in.
Height, rail to trolley base	10 ft. 10 in.
Window post spacing	36¾ in.
Body	All steel
Roof	Arch
Doors	End

Interior of car has an enamel finish and linoleum flooring

Air brakes	Westinghouse SME
Alarm gong	E.S.S. Co's pneumatic
Armature bearings	Plain
Axles	Hammered steel
Car signal system	Faraday buzzers
Compressors	General Electric Co.-CP-27
Conduit	Flexible
Control	Westinghouse VA
Couplers	Portable bar
Destination signs	Keystone
Door mechanism	National pneumatic
Doors	Folding
Finish	Beckwith Chandler enamel
Floor covering	Armstrong linoleum
Gears and pinions	Nuttall
Glass	Plate in vestibule
Hand brakes	Peacock staffless
Heaters	Consolidated
Headlights	Electric Service Golden Glow
Headlining	Agasote
Interior trim	Statuary bronze
Journal bearings	Plain
Journal boxes	Brill semi-steel
Lamp fixtures	E. S. S. No. 27902
Motors	Westinghouse 510-E No. 4, inside hung
Painting scheme	Red
Registers	International R-12 double
Roof type	Arch
Roof material	Wood
Sanders	Ohio Brass
Sash fixtures	O. M. Edwards
Seats	Brill 201-B
Seat spacing	31 in.
Seating material	Deep buff taxi grain leather
Slack adjusters	Brill mechanical
Steps	Stationary
Step treads	Kass
Trolley retrievers	Earll
Trolley base	U. S. 24-A
Trolley wheels	More-Jones
Trucks	Brill 177-E1
Ventilators	Brill
Wheels, type	Rolled steel 26 in. diameter
Wheelguards	HB type lifeguards
Window cleaner	Brill

Okonite Company, manufacturer of insulated wires and cables, announces the appointment of Theodore T. Kennedy as district manager of its Los Angeles office.

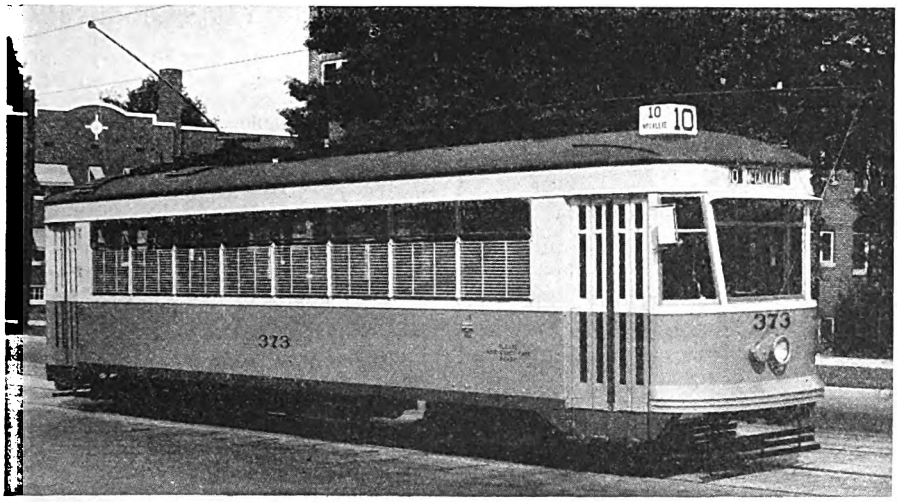
Knoxville, Tenn., Gets New Cars



One of the ten new cars recently delivered to Knoxville Power & Light Company, Knoxville, Tenn., by Perley A. Thomas Car Works. The cars are equipped with pneumatically operated doors, green plush seats and aisle flooring of hard maple wood strips. The car weighs complete 32,500 lb.

Armco Creates Railroad Division for Sales Promotion

American Rolling Mill Company has organized a new division of its sales forces, which will be known as the railroad division. This division will combine the handling of wrought steel wheels, iron and steel sheets and various other products. The headquarters will be at the general offices in Middletown, Ohio. Logan T. Johnston has been made manager, and H. M. Arrick, assistant manager.

Mr. Johnston was formerly with the Standard Steel Car Company, of Pittsburgh, and later assistant to the vice-president in charge of the commercial activities of the forged-steel wheel division. Mr. Arrick, before joining the Armco sales department three years ago, was associated with the operating department of the Pennsylvania Railroad.

Three district offices have already been established. W. B. Quail will manage the New York office, assisted by W. A. Dibblee and E. C. Bray. The latter will be located in the Philadelphia office. Ernest Baxter has been made manager of the Chicago district. He will continue, also, in his present capacity as vice-president of the Sheffield Steel Corporation, in charge of railroad sales. F. E. Finley has been made manager of the St. Louis district.

Bus Deliveries to Electric Railways

Deliveries of buses to electric railways have continued steadily during recent weeks, although at somewhat lower level than during previous months. Twin Coach Corporation reports that the greatest volume of sales for one month in the history of the company was recorded during September. Deliveries for that month are valued at more than $500,000, a gain of more than $100,000, or 30 per cent, over the value of deliveries during September, 1929. Among the deliveries reported by Twin Coach are included twelve urban, small-capacity buses to the Pacific Electric Railway, Los Angeles, and five urban, large-capacity buses to the Boston Elevated Railway.

For the month of September, General Motors Truck Company reports the delivery of five Type W-21 Yellow Coaches to the Virginia Electric & Power Company, Richmond, Va.; five Type U-21 Yellow Coaches to the Memphis Street Railway, Memphis, Tenn.; and four Type W-21 Yellow Coaches to the Mississippi Valley Public Service Company, Milwaukee, Wis.

Deliveries by Mack-International Motor Truck Corporation are reported as three Model AB, 29-passenger buses to Jamaica Central Railways, Jamaica, N. Y., and one Model AB, 230-in. bus chassis to Utah Light & Traction Company, Salt Lake City, Utah. From A.C.F. Motors Company, Illinois Power & Light Corporation, Chicago, accepted delivery of two 25-passenger, parlor car buses, and Capital Traction Company, Washington, D. C., accepted delivery of one 33-passenger, parlor car coach. White Company delivered two Model 65A buses to Louisville Railway.

Financial Statement of G. E. for Nine-Month Period

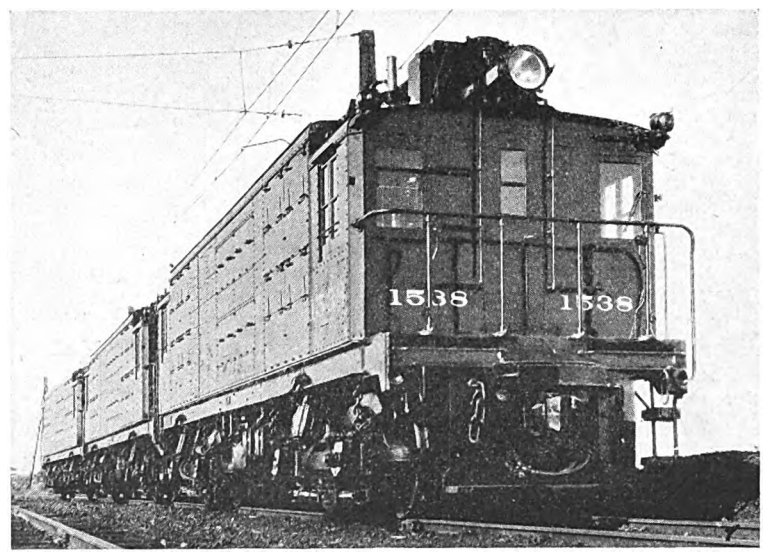
For the nine months ended Sept. 30, General Electric Company indicates a profit available for common stock dividends of $42,518,709, equal to $1.47 per share, compared with $47,965,832, or $1.66 per share on the number of shares now outstanding last year. Comparison of the principal items in the income account for the two periods follows: Net sales billed, $287,886,541, against $301,812,809; cost of sales billed, including operating, maintenance and depreciation charges, reserves and provisions for all taxes, $254,760,877, against $263,316,462; net income from sales, $33,125,664, against $38,496,346; other income, less interest paid and sundry charges, $11,324,254, against $11,400,578; net profit available for dividends, $44,449,918, against $49,896,925; cash dividends on special stock, $1,931,210, against $1,931,093.

Carey Elastite Patent Sustained

In a decision recently handed down by Judge Cooper in the United States District Court in the Northern District of New York, patent No. 1,171,441, under which the Philip Carey Company Elastite rail filler is manufactured, was held to be valid. The Philip Carey Manufacturing Company brought suit against Henry Dumary, an Albany contractor, and the Albany Milling Corporation, a dealer. The infringing rail filler was manufactured and the suit was defended by Serviced Products Corporation, of which Albert C. Fischer, a former employee of the Philip Carey Company, is president.

Judge Cooper's decision stated that the rail filler as manufactured under the patent in question "is a real success and a real benefit to the cities and street railway companies having the problem ever before them of repairing, paving and repaving streets containing railway tracks."

New York Central Gets 42 Electric Locomotives



Three of 42 three-power electric locomotives, ready to leave the Erie, Pa., works of the General Electric Company. The units shown above will be used for the West Side electrification of the New York Central Railroad in New York City. Power may be obtained from a third rail, from a Diesel engine and battery combined, or from the battery alone.

General Car & Coach Corporation Starts Production

Manufacture of standardized street cars and trolley buses for the General Car & Coach Corporation of Albany, N. Y., according to an announcement recently made by President O. F. Warhus, is to be done under contract by the St. Louis Car Company. The cars will be manufactured following the designs developed during the last four years and patented by Mr. Warhus.

Production will be started immediately by an organization already fully equipped with the necessary tools and machinery and with an established reputation for its own products. An advantage of this arrangement will be that no additional capital outlay will be made for equipping a new factory. This is expected to enable the General Car & Coach Corporation to place its product on the market at a particularly favorable price. Sales offices and headquarters have been established at 100 State Street, Albany, N. Y.

Advertising Literature

General Electric Company has published a 75-page booklet, "Heat-Treatment of Steel." This booklet covers briefly the heat-treatment of steel, including hardening, annealing, normalizing, casehardening and tempering. The second part is devoted to the discussion of the effects of electric heat treatment on production costs. Construction and maintenance of G. E. electric furnaces is covered in a third part.

✦

Camden Forge Company, Camden, N. J., has printed for distribution a pamphlet devoted to the discussion of equalizers, drawbars and other forgings of hammered wrought iron, carbon steels or alloy steels.

Railway Utility Company, Chicago, Ill., offers a pamphlet describing heating and ventilating equipment for electric cars, trolley buses and buses.

✦

General Electric Company has issued publication GEA-1228 describing the electrification of the Cleveland Union Terminal.

Westinghouse Sales

Net income during the first three quarters amounted to $11,355,619 after depreciation, reserves and taxes. After interest charges, the balance available for common and preferred stockholders amounted to $11,352,244, or $4.25 a share on outstanding stock of both classes as compared to $7.33 a share last year and $6.03 the year before. Balance available for dividends showed a decline over the nine months of approximately 42 per cent.

A.E.R.A.'s Golden Anniversary Convention

THE 50th, or Golden Anniversary, convention of the American Electric Railway Association will take place in the new auditorium and convention hall at Atlantic City, Sept. 26 to Oct. 2, inclusive, 1931.

In connection with the convention, the operating and manufacturer members of the association will hold the usual exhibition of appliances and other manufactured articles of interest to the managers and other important executives and operating officials of the urban and interurban transportation companies of the country.

A diagram showing exhibition spaces together with application for space will be available to the membership about May 1, 1931.

Lincoln Arc Welding Prize Competition Is Announced

Designers and engineers in every industry, where iron and steel form all or a part of the manufactured product, are again given the opportunity by the Lincoln Electric Company, Cleveland, Ohio, to show their skill and ingenuity in utilizing the advantages of arc-welded construction. There will be awards to the amount of $17,500 for the 41 best papers submitted in the competition. The papers entered in the competition will be judged by the jury of awards composed of the electrical engineering department of Ohio State University under chairmanship of Prof. Erwin E. Dreese. The purpose of this second Lincoln arc welding prize competition, as announced by its sponsors, is to stimulate designers and engineers in every line of industry to think of the manufacture of their own products by the use of arc welding and to increase their knowledge of the feasibility of its application.

Award for the first prize paper will be $7,500; for the second prize paper, $3,500; for third prize paper, $1,500; for fourth prize paper, $750; for fifth prize paper, $500; for sixth prize paper, $250, and for the seventh to the 41st prize papers, $100 each.

The competition will be open to any person in the world except the employees of the sponsors. The closing date for the competition will be Oct. 1, 1931. Other details of the rules of the competition are expected to be announced shortly.

Electric Railway Material Prices—November 1, 1930

Metals—New York

Copper, electrolytic, delivered, cents per lb.	9.50
Lead, cents per lb	5.10
Nickel, ingot, cents per lb	35.00
Zinc, cents per lb	4.00
Tin, Straits, cents per lb	25.50
Aluminum, 98 to 99 per cent, cents per lb	23.30
Babbitt metal, warehouse, cents per lb.:	
Commercial grade	33.00
General service	30.00

Bituminous Coal

Pittsburgh mine run, net ton	$1.25
Central, Ill., screenings, f.o.b. mines	0.75
Kansas screenings, Kansas City	1.40
Big Seam, Ala., mine run	1.50

Track Materials—Pittsburgh

Standard steel rails, gross ton	$43.00
Track spikes, 9/16-in. and larger, cents per 100 lb	2.80
Tie plates, cents per 100 lb	2.075
Angle bars, cents per 100 lb	2.75
Track bolts and nuts, cents per 100 lb	3.90
Ties, white oak, Chicago, 6 in. x 8 in. x 8 ft.	1.35

Hardware—Pittsburgh

Wire nails, base, per keg	$2.05
Sheet iron (24 gage), cents per lb	2.45
Sheet iron, galvanized (24 gage), cents per lb.	3.05
Auto body sheets (20 gage), cents per lb	3.50

Waste—New York

Waste, wool, cents per lb	12.00 to 15.00
Waste, cotton (100 lb. bale), cents per lb.:	
White	9.00 to 13.00
Colored	5.00 to 7.00

Paints, Putty and Glass—New York

Linseed oil (5 bbl. lots), cents per lb	10.2
White lead in oil (100 lb. keg), cents per lb	13.75
Turpentine (bbl. lots), per gal	0.44
Putty, 100 lb. tins, cents per lb	5.50

Wire—New York

Bare copper wire, cents per lb	11.75
Rubber-covered wire, No. 14, per 1,000 ft.	4.55
Weatherproof wire base, cents per lb	12.75

Paving Materials

Paving stone, granite, 5 in., f.o.b.: New York—Grade 1, per thousand	$150.00
Wood block paving 3½, 16 lb. treatment, N. Y., per sq.yd., f.o.b.	2.50
Paving brick 3½x8½x4, N. Y., per 1,000 in. carload lots, f.o.b.	50.00
Paving brick, 3x8½x4, N. Y., per 1,000 in. carload lots, f.o.b.	45.00
Crushed stone, ¾-in., carload lots, N. Y., per cu.yd., delivered	3.40
Cement, Chicago, in carload lots, without bags, f.o.b.	1.95
Gravel, ¾-in., cu.yd., delivered New York	3.40
Sand, cu.yd., delivered New York	2.15
Asphalt (Texas), in package, N. Y., per ton	22.50

Scrap Metal—New York

Heavy copper, cents per lb	7.50
Light copper, cents per lb	7.00
Heavy yellow brass, cents per lb	4.50
Zinc, old scrap, cents per lb	2.00
Lead, heavy, cents per lb	3.75

Old Material—Chicago

Steel car axles, net ton	$15.25
Cast iron car wheels, gross ton	13.75
Steel car wheels, gross ton	15.25
Leaf springs, cut apart, gross ton	15.75
Angle bars, gross ton	13.25
Brake shoes, net ton	8.75
Rails (short), gross ton	14.25
Rails (relaying), gross ton (65 lb. and heavier)	28.50
Machine shop turnings, gross ton	5.50

TRADE NOTES

Cutler-Hammer, Inc., reports for the quarter ended Sept. 30, 1930, shipments amounting to $2,198,116, compared with $2,683,398 in the preceding quarter, and $3,321,450 in the third quarter of the previous year.

✦

Westinghouse Electric & Manufacturing Company offers a new eight-page circular describing a metal-inclosed truck-type switchgear, manually and electrically operated, built for three-phase, 60-cycle supply, 3,000 amp. maximum and 15,000 volts maximum. The circular is identified as Circular 1892.

✦

C. J. Bowers has been appointed production manager of the Lincoln Electric Company's plant in Cleveland.

✦

Ohio Brass Company has declared an extra dividend of $1 per share on the common stock, in addition to the regular quarterly dividend of $1.25 per share, both payable Oct. 15 to holders of record Sept. 30.

✦

Harold F. Kneen has been appointed plant superintendent of the Lincoln Electric Company, Cleveland, Ohio, manufacturer of "Linc-Weld" motors and "Stable-Arc" welders. Mr. Kneen, who is a graduate of Cornell University, with the degree of mechanical engineer, came to the Lincoln Electric Company as assistant plant superintendent in June, 1929.

✦

Paramount Cab Manufacturing Corporation and subsidiaries announce, for the year ended Sept. 30, a net loss of $280,912 after depreciation, interest and other charges. This loss compares with a net profit of $1,115,981, or $4.46 per share last year.

Volume 74 New York, December, 1930 *Number 13*

Santa Claus: His Name Is Service

IN THE welter of comment on the recent election about the attitude of the Pinchots, the Roosevelts, the Crosses and other gubernatorial and minor candidates toward the utilities, sight has almost been lost nationally of the significance to the electric railways of the results of the referendums in the state of California, in San Francisco, in Boston and in Omaha. In several of these places the issue was hotly contested, but in every instance the outcome was favorable to the transportation companies.

In California the plan to revise the state tax on electric railways was approved. This measure is significant in that the electric railways will be taxed in the future at a rate more in proportion to that of other utilities and to private property. In San Francisco both the issue to limit the fare on the municipal railway and the one to extend the franchise of the Market Street Railway for twenty-five years were hotly contested. The Municipal Railway proposal was defeated. The franchise extension won. Even the stoutest local advocate of municipal ownership was forced to admit that municipal ownership of the railway had reached the deficit stage and that in all likelihood the deficit would become progressively larger.

The worst that the loudest opponent of the Market Street Railway could say against that company was that "the Market Street Railway has now for years been working itself into the good graces of the people—giving good service and especially giving courteous service, looking out for every little angle that means pleasing the public." This, indeed, was a trying situation. As the *Wall Street Journal* so aptly said, it showed how the "interests" are ever devising new schemes to exploit the public.

In Boston the voters had the choice of returning the system to private ownership and management, continuing public control, or going to municipal ownership. A substantial majority was returned for the present plan of public control. There, too, the issue was vigorously contested. Each proposal had its renowned adherents. The advocacy was forensic but seldom vituperative. Now the Legislature, by mandate of the people, has been definitely appraised of the feeling of the public in the district served by the Elevated. The result is to lift the perennial debate over the Elevated out of the arena of politics and place the mass-transportation system of Boston in a position to build safely, strongly, and well.

In Omaha the plan to construct a competing bridge over the Missouri River to parallel the structure of the Omaha & Council Bluffs Street Railway was defeated. Here again virtue is its own reward, for the vote is one indicating confidence in the present management policies for the railway as laid down by President Shannahan and his associates.

By amendment to the constitution of the state of Utah, a tax commission was created in whose hands will be placed the task of assessment of all public utilities. Formerly utilities serving communities within a single county were assessed by the county assessor. This charge should result in more equitable utility taxation throughout the state.

Judged by these referendums and the outcome of the vote in Chicago earlier in the year, if there is any Santa Claus for the electric railways where public issues are involved, his name is Service.

Naming the New Baby

CARE always should be exercised in christening a new baby, as the name given in infancy cannot well be changed in later life. That is true also of a new type of transportation vehicle, and it would be well at this time to devote some thought to the latest development—the rubber-tired vehicle propelled by electric motors deriving their energy from an overhead contact line.

More than a decade ago, a vehicle having a certain similarity to the present vehicle, yet in reality quite different, became known as the trackless trolley. Opinion is practically unanimous that this unattractive name should be relegated to the scrap heap, where many of the original vehicles have already gone.

Several names have been suggested for the modern type of equipment. Among them are electric coach, electric bus, trolley coach and trolley bus. Good reasons exist for not using either of the first two. Confusion would inevitably arise from the similarity of the terms gas-electric bus and electric bus. Moreover, the vehicle actually is not an electric bus or coach. Those names properly belong to vehicles deriving their power from storage batteries. While few storage-battery buses are in service any longer, there are a sufficient number of storage-battery trucks to perpetuate the association between the name electric vehicle and storage-battery operation. Most important of all, however, is the reason that the public would be unlikely to adopt any such name. Were it adopted by the local transportation industry, it seems probable that the public would ignore it and use the old and undesirable appellation, trackless trolley.

Between the names trolley coach and trolley bus, there is not much to choose. Both describe the vehicle with reasonable accuracy. Endless arguments have been waged concerning the exact meaning of coach and bus. A hundred years ago, it may have been true that a coach was an imposing and elegant vehicle to carry the gentry on their travels, while a bus was a cheap, crude omnibus for the accommodation of the common herd. Nowadays, however, no such distinction exists. The steam railroads

Digitized by Google

use the word coach to distinguish an inferior class of accommodation as compared with the Pullman car. On the other hand, a number of electric railways use the term motor coach to distinguish a type of service superior to that given by the ordinary bus.

In England, where this type of vehicle has been widely used for some years past, the term trolley bus is universally used. Practically all the electric railways in the United States operating this kind of service call it a trolley bus. The manufacturers of the vehicles and the equipment required for their operation are virtually unanimous in favoring the name trolley bus. All things considered, it appears that the term trolley bus best fits the vehicle and is most likely to be adopted by the public if used by the industry.

Manufacturers Show Confidence in the Industry

REAFFIRMING their faith in the elemental soundness of the electric railway industry, the manufacturers' representatives attending the recent meeting of the A.E.R.A. Convention Exhibit Committee promised to take as much or more space in 1931 as was used by their companies in 1929. Coming after a period of prolonged depression, and at a time when the industrial horizon is still clouded with elements of doubt and uncertainty, the decision was a courageous one. There was no hesitation, no equivocation. A full year in advance of the event the members of the committee, representing a score or more of the leading manufacturers put themselves on record by underwriting the success of the exhibit of the 50th annual convention.

This action of the committee is more than a mere gesture of confidence. It is a definite expression of faith on the part of hard-headed, calculating business men. It indicates a belief in the early restoration of the buying power of this industry. As any increase in buying power of the railways is predicated upon an increase in revenue which can come only with business recovery, it may be assumed that the manufacturers, taking a broad view of the situation, look for an early end of the present depression.

The electric railways were among the last to feel the effect of the decline. It does not follow, however, that they will be among the last to recover. It is not too much to hope, in fact, that they may be among the first to get back to normal. The courageous action of the exhibit committee in planning for a record exhibit of electric railway materials is a step in this direction.

Making Faster Street Car Operation Practicable

WITH general street traffic in the larger cities becoming more and more congested the need for public transportation vehicles that can fight their way successfully through the maze and maintain speeds as high as or higher than the average on the street becomes daily more apparent. The street car, while its maximum speed is more than ample for city conditions, is handicapped by the characteristics of the motor that prevent acceleration at a high rate up to anywhere near the top speed.

More power on the street car undoubtedly would be of material advantage, not only in permitting a higher initial acceleration, but in maintaining that rate long enough to bring the car up to the maximum permissible speed, thus not only allowing the car to keep up with the procession of automobiles but allowing it to take advantage of any opportunities to get ahead. Electric railway men usually have put aside the idea on the basis of cost. Not only are larger and heavier motors required, but the power demands and the energy cost will certainly be greater. However, as J. W. Welsh shows in this issue, the extra cost may well be made up by a reduction in the labor charge by virtue of the faster schedule. With the present trend toward lower car weights, there may be the possibility of getting the higher accelerations demanded with no great increase in the power drawn from the line.

Series motors have been used for street railway power so long that few engineers consider any other type suitable. From time to time inventors have urged modifications of the series motor for the purpose of obtaining regenerative control, with a return of energy to the trolley. These plans have been so complicated that none of them ever has come into general use. However, the plan being tried in Paris, France, and discussed in this issue indicates that a way has been found to use compound motors which not only is less complicated than the older plans for regeneration, but which will give a more satisfactory control of speed and power than series motors will permit. Furthermore, it has the advantage of regeneration without any special attention on the part of the motorman.

These new developments indicate that the entire subject of railway motors may well be opened up once more. Certainly the need exists for equipment that will not block the streets. The possibilities of such plans as these, or of other plans that may be devised under the spur of competition, merit the most earnest consideration.

Seattle's Municipal Railway in Insolvent Condition

SEATTLE'S attempt to run its railway has failed and failed miserably. It did not need the recent report of the citizens' committee to make that plain. That was patent long ago. But it did take the report of the citizens' committee to establish the extent of the failure. Seattle's municipal railway is in an insolvent condition. There has been too much public pressure. But the situation is not without hope. According to the committee, the system should be placed in the hands of an operating body as free as possible from public pressure.

The committee suggests almost an entirely new deal for the system—a deal that takes cognizance of relief for the railway from paving burdens and other onerous charges. This is significant to private companies seeking relief from similar imposts on the score of their unfairness. The most significant thing, however, is that the city has failed in its attempt to amortize the purchase price out of earnings. That it would so fail was a foregone conclusion, but now the fact has been established beyond the possibility of a quibble.

But after all the crowning presentment of the committee was the statement that the whole trend of government for the last half century has been to make all government more responsive to the public. This may be all right in government, but not necessarily in business.

Digitized by Google

And then the committee says, "Operation of the street car line is business." It would, indeed, be difficult to make eight words say more.

In this connection, it is well to note some interesting parallels between the Seattle and Portland situation as illustrated by this report, on the one hand, and the Carey & Harlan plan for Portland, on the other hand. In the first place, the Seattle report bears a very close relation to the Carey & Harlan plan in its treatment of the paving problem. The language and arguments in favor of transferring the burden of paving between the tracks to some support other than the department in the one instance, and the company in the other, are nearly identical.

For Portland, Carey & Harlan advocated that the city acquire the tracks and pavement between the tracks, and assume responsibility for construction and maintenance. In Seattle, the department has been attempting to take care of such items of expense out of railway revenues, but now proposes to transfer this burden to the general taxpayers or assessment districts. Seattle, however, would go farther and tax automobiles, diverting some of such tax money to the purpose of building and maintaining streets.

The utter failure of the Seattle Railway Department to amortize its investments out of earnings, and at the same time maintain its physical property is no surprise to those familiar with transportation problems. Whether the plan for Portland, calling for the amortization of the company's investment in tracks and streets, out of earnings, can be successfully accomplished is problematical. In some respects, Portland is at the crossroads. It should proceed cautiously.

Undermining an Essential Service

DISREGARDING the costly lessons of past experience, municipal authorities in numerous American cities are permitting a new kind of transportation rate war to develop. Cut-rate taxicab service by irresponsible individuals has been allowed to grow to a point where it threatens to undermine organized transportation service. While most of these cheap taxi operations are on an extremely unstable financial basis, it appears that the operators may be able to make both ends meet so long as they are not compelled to assume any definite service obligations. In many localities they have cut deeply into the revenues of mass transportation agencies.

On the surface, the harmful effects of cut-rate taxicab operation are not clearly visible. To the man in the street it appears that the taxicab operators are able to make a living and the users of their service benefit by its cheapness. Hence, he is content to let the situation stand as it is.

That view, however, takes no account of other factors of vital importance. The effect of cut-rate operation extends far beyond the taxicab operator himself and his patrons. It is depriving other transportation agencies of revenue essential to their successful operation. It is undermining a service which it cannot replace. Under no imaginable circumstances could the taxicab become a satisfactory substitute for the street car or bus. For several people going to the same destination, it might be possible to travel cheaper by cut-rate taxicab than to travel by street car or bus, but for individuals traveling alone the cost would be excessive. Moreover, the streets of our cities are already too congested to accommodate the vast number of vehicles that would be required to perform mass transportation service by taxicab.

In view of these facts, it is clearly in the public interest to protect the mass transportation agencies from this destructive competition. This can be done only by adequate regulation of taxicab operations. The number of cabs should be limited to the legitimate demands of public convenience and necessity. Experience in the six states where this has been done on a state-wide basis, and in about a dozen cities in other states where it has been done by local ordinance, shows the value of such limitation. If reasonable service standards are required, taxicab fares will automatically be placed on a fair competitive basis. To the business they can secure on that basis the taxis are honestly entitled. But to permit irresponsible taxicab operators to continue to take business from established agencies required by law to maintain high service standards can result only in disaster to the users of public transportation.

Progressive Management Requires Research Support

DEFINITE need exists for fact-finding research in the electric railway field. That it has been employed to a considerable degree by many companies is evidenced by the constant development and improvement in practically all phases of railway operation during an era in which gross revenues have been steadily declining. The introduction of such competitive factors as the automobile, the bus and the low-rate taxicab forced the railways to search their own operations for economies, for the elimination of waste and, in general, for practices that would result in a lower operating ratio. In this they have been remarkably successful as shown by the steady increase in net revenue of the industry and improvement of physical plant, which occurred up to the beginning of the present business depression.

Necessity, however, has not been wholly responsible for research or experimentation in the past. A certain "research-mindedness" is natural to an industry using a large amount of complicated electrical and mechanical equipment. Much has been done along these lines but the railways have not until recently applied research to the problems of management. In that field the value of research is even greater. From the broadest operating policy to the smallest detail, management is responsible. Unless it can see clearly and without prejudice the facts supporting its practices, the facts that remain sound, those that have become obsolete, and the new facts which may have entered into the situation, successful results are impossible.

Many railways are making energetic efforts to operate on a factual basis and are employing research to keep pace with changing conditions. Not many, however, have placed research in a position to be really effective. The research engineer must be free from the stress of operating responsibility; he must be in a position to co-ordinate effectively the problems of management and the efforts of his department workers in solving them, and he must have the authority to follow up the results of research and demand the utilization of its findings. If management is not willing to give research this major position in its organization, operation becomes a habit and practices change only under the forces of emergency or on the unsupported conclusions of personal opinion.

RESEARCH DEPARTMENT

Aids Railway Operations

Pittsburgh Railways Endeavors To Conduct Its Operations on a Basis of Facts Disclosed by Systematic Investigation. Detached Research Group Is One of Major Departments. It Is Composed Principally of Individuals Transferred from Other Departments

MANAGEMENT research, or an orderly application of simple but sound methods in the effort to solve everyday problems, is a major factor in the operations of the Pittsburgh Railways. This company has long been among the leaders in experimental research—principally in car design. Such habit of thought naturally led to a recognition of the fact that approaches to all problems are fundamentally similar, though they may vary infinitely in detail, and that the same procedure which had proved so successful in dealing with technical problems could be applied to the difficulties confronting management. In recent years street railway managements have found themselves faced with constantly changing conditions and in need of every instrument that could be found or devised to help identify previously determined facts which remained pertinent, point out those which had become obsolete, and discover the entrance of new facts. Consequently, a research department was established for the purpose of bringing to the aid of management those practices and methods that had been accepted as matters of course in technical and experimental research for many years.

Fundamentally, the research department is separate and detached from all other departments in the organization. It is non-competitive in the strictest sense and is furnished as an instrument by the management for the use of officials and employees. The measure of the utility and value of the department is in the consumption or use of its findings or research releases.

As the department exists now, it is composed chiefly of individuals transferred from other departments. When first organized, it consisted of a research manager, a research engineer, a combined stenographer and routine office worker, and a small statistical group which had been doing statistical work for the operating management.

For about two and one-half years the department continued to function approximately as organized. Then it was re-organized, consolidated with the general operating offices and placed under the supervision of the assistant to the vice-president, whose title was changed to "research manager."

The work is divided into three sections: that done by an analyst or economist; an engineering division, in charge of a research engineer; the general operating office in charge of an office manager.

The work referred to the analyst consists of studies and researches where the broader principles of economics are involved. The economic factors involved in fare structure, pensions, insurance, etc., are typical.

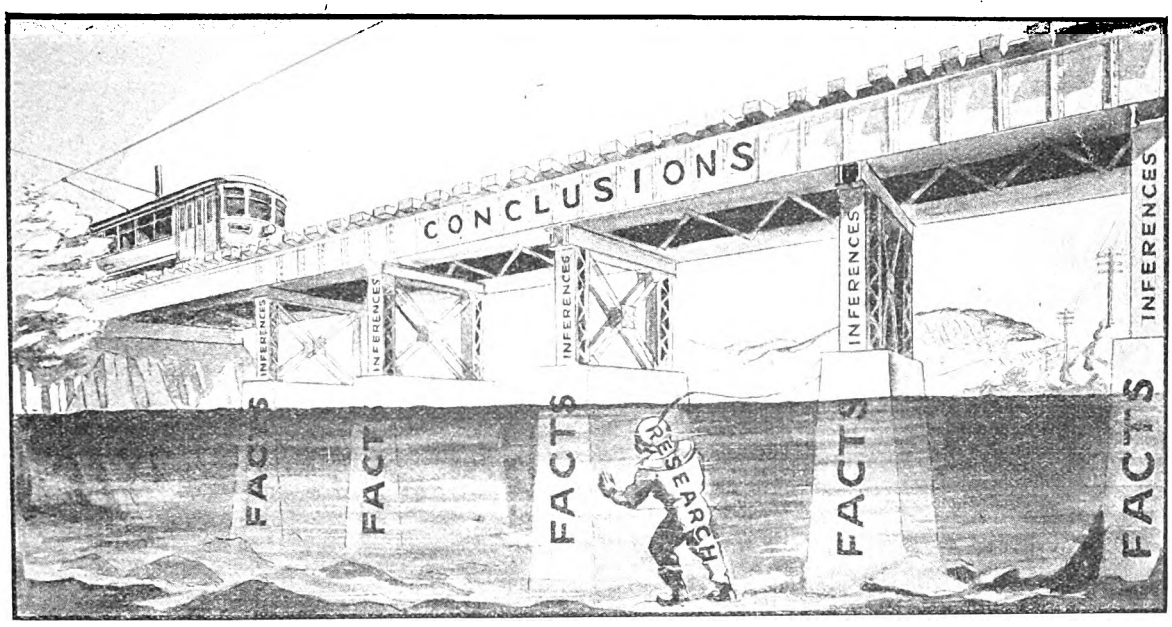
The engineering division, as indicated by its name, is engaged in practically applied research engineering. It is in charge of a civil engineer, with the title of "research engineer," who was transferred from the roadway department. This division has been manned completely by bringing in employees from other departments rather than importing highly trained specialists from other fields. The type of work ranges from studies designed to influence important decisions in policy to clarification of troublesome details.

In addition to a group of engineers, the research engineer has a supervision over a statistical section, a recurrent work section, and a budget section.

The statistical section supplies certain statistics required by the operating management, and those needed in the development of research studies. The recurrent work section originally was a group of clerks set aside to do work of such a definitely recurrent nature that the jobs could be scheduled with a fairly reasonable degree of exactness. It was found that, by an extremely simple method consisting of element identification and requirement for reauthorization at reasonable intervals, continuance of any recurrent clerical work, after it had ceased to be profitable, could be avoided. The benefits secured have been so evident that an engineer has been placed temporarily in charge of analysis and studies incident to installation of similar methods in operating departments. The budget section is engaged in formulation of annual operating and improvement budgets and revisions thereof. This section also maintains comparisons of actual performance with budget estimates and conducts such analyses as are deemed necessary to bring out pertinent facts.

The general office division, in charge of an office manager, which performs office service for all operating general offices was combined with the research department for reasons of economy and effectiveness. The department, when first organized, suffered from lack of stenographic assistance. The consolidation has not only corrected this situation by making available a larger and more flexible group, but the orderly method which permeates activities has been beneficial to office operation. There is now one general file which also serves to pre-

Digitized by Google



Systematic examination of underlying facts is essential in determining the soundness of conclusions

serve research material where formerly there were several departmental files.

The responsibility of the research manager consists of achieving co-ordination between the department and other officials of the company as well as among divisions and individuals of the department. He is responsible for the initiation of research projects, their placement in priority, their production, their presentation, and to a degree their consumption. He is chairman of an advisory council which is composed of the heads of the commercial department, department of maintenance and construction, department of traffic and transportation, and the Pittsburgh Motor Coach Company. Placed in this manner on a level with all other department heads who report to the operating vice-president, he has an opportunity to co-ordinate the activities of the research department with all operating activities. The research engineer is chairman of an operating committee composed of operating executives who report to some member of the advisory council. This arrangement further extends the opportunity for co-ordination.

Neither the research manager nor the research engineer has operating authority or operating responsibility. Both are charged, however, with the responsibility to exhaust their efforts to see that all pertinent facts are considered in the discussions over which they preside. Such an attitude of "research-mindedness" on the part of the management of the Pittsburgh Railways has been the dominating factor in the successful operation of the research department.

The Cost of Research Work

Management research, as the Pittsburgh Railways is endeavoring to use it, is not some new experimental thing intact in itself, superimposed upon the former type of operation. It is more nearly a regrouping of service units with certain additions, all of which are operating in a detached research atmosphere. This arrangement was induced by an attitude which admits the existence of rapid change and the necessity of making use of whatever scientific principles experimental research has developed in any field. The net result appears to be simply a concentration of effort and an improved production of usable material for the support of management in dealing with everyday problems. The description of the organization indicates that numerous types of work and service other than the development of purely research studies are performed. It is obvious, therefore, that purely research studies share the burden of overhead costs with other types of service common to all companies.

The cost of actual research work is almost as flexible as the cost of piece work, as its expansion or contraction is governed by work units.

Following is a table showing, in percentages of payroll, how the energies of the department are divided:

Division of Department Energies

	Per Cent
Reports and studies	39
Statistics in support of reports and studies	6
Recurrent statistical and clerical work	13
Budget work	10
Welfare work—investigating cases of unfortunate employees and arranging loans	3
General office service for the vice-president, general superintendent of transportation and traffic, general superintendent ot maintenance and construction, Pittsburgh Motor Coach Company, research department, and file service for commercial department	29

Not all research work of the Pittsburgh Railways is confined to the research department. Technical and experimental work has been continued in departments where it is obviously practical. In such cases individuals have been partly or completely freed from operating responsibilities, and an effort has been made to provide working conditions where detached thought is possible.

A further insight into the activities and scope of the Pittsburgh Railways research department is made possible by examples of specific studies which have either been released or are now in progress:

- Car design
- Fare structures
- Motor coach routes
- Wage agreements
- Trolley bus
- Operating estimates
- Incline operation
- Retirement plan
- Insurance
- Test of air in Mount Washington Tunnel
- Time-keeping methods
- Studies of revenue trends
- Motor coach tests and experiments
- Track relocations
- Safety islands
- Statistical studies

Digitized by Google

While recurrent statistical work can scarcely be termed "research," jobs such as are listed below are done. This is purely clerical work which can be done whenever it is deemed most expedient. It is carefully controlled by identified work units and is made to fit immediate needs of the management. The units recur with sufficient regularity to permit scheduling. The following are typical:

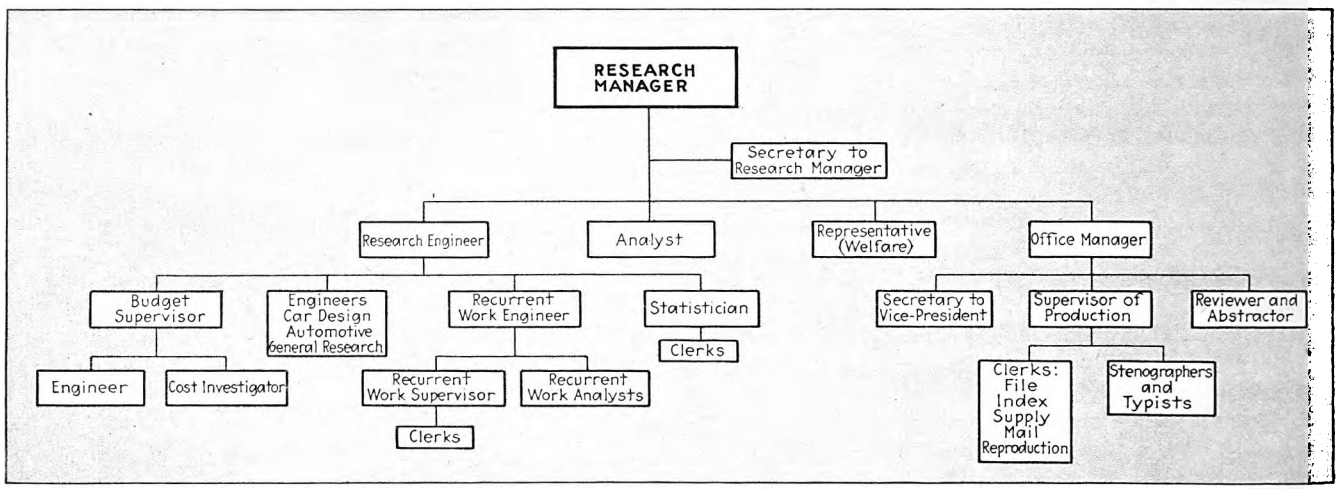
Detailed analysis of operating expenditures.
Analysis of storeroom materials and supplies, withdrawals.
Analysis of complaints and commendations.
Analysis of accidents.
Analysis of car turns.
Analysis of trainmen's wages.
Analysis of time allowed trainmen in excess of scheduled time.
Analysis of sick absenteeism.
Preparation of daily report of car-miles operated—by route.

Sound Production Methods Essential

The opportunities for improving production both as to timeliness and economy through elimination of waste became more and more apparent as the experience of the job or jobs under active production; the second, those jobs waiting for material; the third, four or five jobs chosen with care to move into production next; and the fourth, jobs which are waiting in a selective line for later movement into production. Since the daily priority change involves no clerical work but simply movement from one compartment to another, the time required for maintaining the method is next to nothing.

A project placed in priority is considered as a product to be manufactured and consumed. At no time is there a question in the mind of any employee, his immediate supervisor, or the department manager as to which jobs constitute the employee's immediate, entire responsibility. Establishment of priority is the job of the department head, and whenever it is tossed to one not actually responsible for it, waste is bound to result.

The handling of recurrent work is as carefully organized as that coming under the head of non-routine work. Each item of routine work which may recur with regularity either daily, weekly, or monthly, must carry an



Co-ordination of the research and general office personnel of the Pittsburgh Railways has produced an efficient and economical organization

the department increased. The wastefulness of unsatisfactory work, either because of misunderstanding of objective or other reasons, stimulated serious effort to secure a better understanding of the elements which help or hinder desk-workers. The result has been the creation of methods designed to make the most of helpful factors and to avoid the destructive ones. A research worker cannot achieve reasonably satisfactory production unless his working conditions include at least the following:

1. A common understanding in fact with his supervisor as to the scope of a job, the objective, purpose, and the time factor.

2. The priority of the unit of work given him should be definite. Conflicting demands, where definite priority of units is ignored, destroy the possibility of good jobs. Such is not thought of where the work units are tangible, as in a shop.

When a job comes to the department, it is set up as an identified work unit, entered in a ledger and numbered consecutively. The job is then set up on a small sheet of paper which fits a pocket-sized, loose-leaf note book. The research manager has a book for each worker who is assigned non-routine jobs. The worker and his immediate supervisor have duplicates. The books are divided into compartments, the need for which has been indicated by experience. The first compartment holds authority. This authority is repeated at intervals to obviate the possibility of work being done after its value has passed. The accumulation of useless clerical work is thereby prevented and valuable work is not kept waiting because of unprofitable use of a clerk's time.

Effective Follow-Up Essentials

The research department is non-competitive and makes no attempt to show specific economies and other achievements to which it has contributed. The department's chief aim is to perform a useful service which can only be accomplished by a co-operative effort on the part of recipients of releases to profit by the work done. Consumption does not mean the blind acceptance of a research department release. It does not necessarily mean acceptance at all. But it is the policy of the company that the releases cannot be ignored. If an operator can take issue and support his position, he is expected to do so, and such action is considered to be consumption. If evidence of such use is not apparent in a reasonable time, inquiries are made and follow-up procedure instituted. If necessary, the research manager is expected to formally request consideration of the release, with copies of such request going to other members of the advisory council and to the vice-president. An authorized follow-up procedure is a factor of prime importance in the

Digitized by Google

effectiveness of a research department, and is a definite recognition on the part of management that, if it is to endeavor to base its policies and operation on a factual basis, the results of research effort are all pertinent to the subject involved. The consumer is not only expected to differ, but it is considered his duty to do so if he can justify his position. Furthermore, the research department is expected to welcome conflicting views, and to help secure material to support such opposition—all as a fact-finding effort. But any prospective consumer who fails to do all he can to make the most of the work done by the research department and to exhaust the releases for whatever helpful material they may contain is acting contrary to company policy.

The research department in Pittsburgh has definitely dispelled the general idea that only highly trained technical men are suitable for research work. In highly technical matters, the specialist is required and used, but he is treated as a specialist and is retained for the particular project requiring his services. For the everyday research worker the department depends upon the man of practical intelligence—one who is inclined to develop an accuracy in observation, to draw reasonably sound inferences, and to use good judgment. In addition to this, it is imperative that he develop a persistent concentration which drives him doggedly into his problem. Engineering training is regarded as a distinct asset, but not an assurance of research performance of a high grade. Some individuals who are not engineers are delivering excellent work. The experience of the department points to the value of an attitude which accepts constant change as an inevitable fact and fears both undue emphasis upon particularities and conclusions which may once have been sound but which have become obsolete.

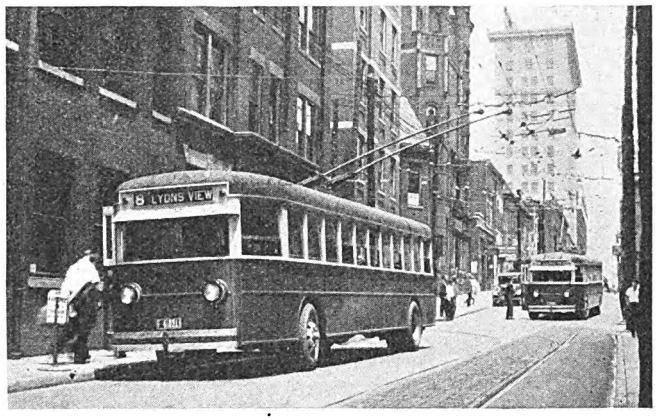
Knoxville Trolley Buses Increase Patronage

FAVORABLE expressions of opinion indicate that the trolley buses placed in service by the Knoxville Power & Light Company on April 28 are being well received by the public. More tangible proof, however, is found in the 15 per cent increase in riding which has occurred on the Lyons View line. Apparently, the patrons are being attracted by the speed, quietness, convenience and flexibility of the new vehicles.

Service on this line previously was given by electric cars which operated through paved streets to the city limits, and from there to the end of the line on open track at the side of the highway. About a year and a half ago the company was faced with the problem of rehabilitating and extending the car line. Subsequently, it was decided by the City Council of Knoxville to undertake street widening and repaving. Negotiations with the company resulted in a decision to remove the track and install trolley buses. Accordingly, four trolley buses, with a seating capacity of 43 passengers each, were ordered from the Cincinnati Car Corporation. Actual service was begun on April 28, 1930.

At the present time, two of the vehicles are used during base hours on a 30-minute headway. During rush periods, all four are used and the headway is reduced to fifteen minutes. Daily vehicle-miles total approximately 527. Because of the higher acceleration and breaking rate, as well as higher free running speeds, the vehicles are able to maintain faster schedules on the line. The former time of one hour and fifteen minutes for the round trip has been reduced to one hour. The average scheduled speed for the run is 10.54 m.p.h.

The route, as shown on the accompanying map, extends from the heart of Knoxville's business district to a point to the southwest, a distance of 5.27 miles. In the business district the vehicles enter on Clinch Street and loop around through Walnut, Union and Gay Streets. The streets are extremely narrow and congested there, but the trolley buses operate satisfactorily, even on the

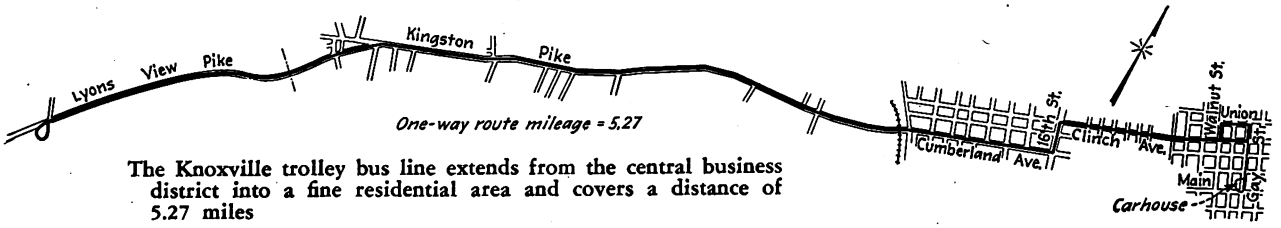


Trolley buses in the business district of Knoxville

sections of the route which are duplicated by street car lines. Downtown the trolley buses use the raised concrete loading zones provided for street car patrons. After leaving the business district the route enters one of the finest residential districts in the city.

In the business district the trolley buses use the same positive contact wire as do the street cars. At intersections where street cars operate straight through and also turn, a special mechanical frog, developed by the Ohio Brass Company, with tongue actuated by a tripping device on the negative wire, is used. As the latter is only used by the bus, the passage of a trolley wheel can be utilized to set the frog tongue in the positive wire. It other instances turnouts are provided with electrically operated frogs.

The vehicles are stored and maintained at the Main Street carhouse which is located 0.14 mile from the regular route at Gay and Clinch Streets. To allow for satisfactory inspection and repair, guards were placed along the sides of one of the car pits and double trolley installed over one track in the repair section.



The Knoxville trolley bus line extends from the central business district into a fine residential area and covers a distance of 5.27 miles

Extensive Rehabilitation

Forty new cars of this type were recently placed in service by the Des Moines Railway

Purchase of 50 new cars, complete transformation from two-man to one-man operation, remodeling of all rolling stock, betterment of service, improvement in power system and effecting of major economies among steps taken by new management

By LAURENCE WINGERTER
Publicity Director Des Moines Railway

WITHIN a period of a little more than a year the Des Moines Railway has carried out an improvement program which has included almost every part of its physical plant, and which has affected every phase of its operation. Definite results already realized are lower operating expenses and a better state of public relations. With the return of business conditions to normal it is anticipated that the new equipment, higher speeds and general improvements in service will cause an increase in patronage. With more business and lower expenses, the company should have a satisfactory showing, reflected in the net.

Announcement of the plans followed the purchase of the Des Moines City Railway at the receiver's sale on June 22, 1929, by Walter J. Cummings and Charles G. Adsit. The new company, with the name changed to the Des Moines Railway, was incorporated and took formal possession on July 15. Officers of the company now are Mr. Cummings, chairman of the board, Mr. Adsit, president, and C. W. Gifford, general manager. Mr. Gifford has had direct charge of the rehabilitation.

Of the major moves made by the new management, two are of outstanding importance—the purchase of 50 new cars and the complete change-over from two-man to one-man operation. Previous to the change-over, it was necessary to remodel 101 of the company's cars. In this work, standardized motors and other parts were adopted, new fare registers were installed, many safety devices were added, and other modern equipment installed. Following the purchase of the new cars, 40 street cars of an obsolete type were retired. Among the other steps taken were the speeding up of schedules, merchandising the service, effecting economies and improving the power system.

Ten of the 50 new cars were ordered shortly after the reorganization of the company. They were of the double-truck, single-end type, arranged for one-man operation. Individual leather-upholstered seats were provided and special attention given to interior decorations and lighting.

During the current year, 40 additional cars of modern design, built by the Cummings Car & Coach Company, were delivered. These cars have a well-balanced design, attained by wide-vision windows, a narrow letterboard and a low arched roof. A detailed description of the cars appeared in the July, 1930, issue of ELECTRIC RAILWAY JOURNAL.

SCHEDULED SPEED INCREASED

Coincident with the installation of the new cars and the adoption of one-man operation, the railway increased the number of cars in peak service from 108 to 140, or

Digitized by Google

Places Des Moines in Favorable Position

New standard uniform and cap of special blue-gray fabric which replaced the old standard blue serge suit and stiff cap used for many years

30 per cent, shortened the headways, and speeded up its schedules. All one-man schedules, both base and peak, are as fast as, or faster than, the two-man schedules of the same line. Weighted averages show an increase from 11.11 to 11.61 m.p.h. for base hours, and an increase from 10.84 to 10.97 m.p.h. for peak periods. Likewise, all headways were shortened or remained the same. Reductions on certain lines were as great as four minutes in base operation, five minutes in the afternoon and two minutes in the peak.

Express cars, operated by one man, have been inaugurated on several lines, and have proved popular with the riding public. In the near future the company plans to extend express service to every route where existing track facilities permit.

For busy lines, where cars are only two and three minutes apart during rush hours, company engineers have developed a novel plan, to be tried soon, known as "relay express service." In starting the system an extra car will be placed in service near the outer end of a line and run as express, making no stops to pick up passengers, until it overtakes the car immediately ahead. Then, upon exchanging pre-arranged signals, the first car will become an express and the second car a local.

Cars are being equipped with field tappers to increase the speed, and quick application valves have been installed to reduce the time of stopping. Electric track switches and new automatic signals have been installed as additional time-savers, and two snow sweepers have been purchased to speed the clearing of lines in winter.

Efforts to merchandise the service have included the adoption of new trainmen uniforms, instruction in selling of rides, the creation of a company publicity department, and the adoption of a new transfer system. All publicity now originates in the company. By adopting an open attitude a friendly relationship has been built up with the press. News stories regarding company affairs are sent to all daily and community newspapers, giving correct accounts to the readers.

In all newspaper advertising two points are stressed—economy and service. And in every case the psychology is followed that "Almost everybody's riding with us. Why not you?" A typical economy advertisement, one of eight in a thrift series, is illustrated. Several other media are used for advertising—inside car cards, front and rear dash posters, the latter proving effective for directing messages to motorists, billboards, radio, direct mail, city maps, pamphlets and a car which is given new messages for the public every 3 months. The theaters run trailers in exchange for advertising of current movies on the cars. Another co-operative plan is the giving of a weekly pass with information about the service to new families in the city, along with gifts from various sponsors, distributed by a "hostess" in her "welcome wagon." A follow-up letter is mailed later to ask if the service has been satisfactory.

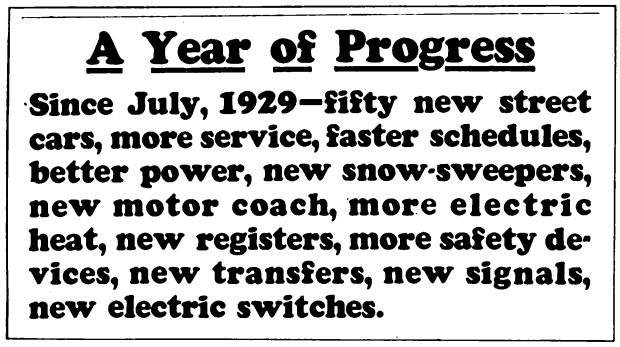
Example of newspaper advertising, stressing the thrift of riding cars

Power Distribution System Improved

Three projects were included in the program for bettering the power supply—the complete rehabilitation of the power plant, the stringing of new feeder cables, and the construction of a new substation. Improvements in the railway's 14,000-kw. power plant included the installation of vertical baffles and Dietrich arches in all boilers, and the purchase of additional gages, pumps and auxiliary devices for regulating generation. Better firing, more efficient boiler conditions and increased economy have resulted. A total of 5,000 ft. of 500,000 circ.mil copper feeder cable was strung on the Sevastapol line, increasing trolley voltage and lowering operating cost. With the new feeders, car speeds were increased

Digitized by Google

and peak headways were reduced from fifteen to thirteen minutes without the use of additional cars. The new substation was constructed at the West 24th Street carhouse. Special transformer and rotary rooms were constructed, and a 1,000-kw. synchronous converter was placed in service. Following this change 6,000 ft. of additional feeder cable was strung and power conditions were improved on three lines.



Inside car poster, depicting the progress made by the company during the year

Major economies, aside from those effected by the use of new cars and the adoption of one-man operation, have been brought about by the consolidation of departments, elimination of the all-day line trouble crew, suspension of the bridge crew, replacement of advertising agency with a company publicity department, elimination of supervisors' automobiles, and installation of storage gasoline tanks for bus fuel. In the consolidation, the purchasing and stores departments, the power plant and car shop mechanical departments, the auto and bus repair shops, and the power plant and substation departments, were combined, respectively. It is significant that operating costs have been reduced from 28 cents, including depreciation, to 23 cents per car-mile.

Opposition to One-Man Operation

Complete transformation of service and equipment from 100 per cent two-man operation to entire one-man operation was the task required of, and accomplished by, the Des Moines Railway in the short period of six months. One hundred and one cars were remodeled between Feb. 15 and June 1, 1930, the first actual one-man service was started on July 4, and 100 per cent one-man operation was completed on Aug. 18.

Serious political opposition and objection from the trade unions presented a real problem for the company. During a political campaign in March, 1930, pledges opposing one-man operation were secured from all candidates for election to the City Council. Petitions opposing the substitution also came to light in various portions of the city and were presented to the Council, along with a suggested draft of an ordinance designed to prohibit one-man cars. On April 24 the first reading of the anti-one-man car ordinance was passed by the Council.

Meanwhile, the railway launched a campaign of education in which the merits of one-man operation were explained in talks to luncheon clubs and community organizations, and by car card and newspaper advertising. This was supplemented with a successful drive to secure a counter petition through the efforts of foremen and office employees. Presentation of this counter-petition and resolutions of various clubs and civic groups to the City Council changed the attitude of this body.

During this period, the entire rolling stock of the company, with the exception of 40 obsolete cars doomed for the scrap heap, was being overhauled for immediate one-man operation. As the cars were completed they were placed in regular service with two men on each car. The conductor, however, was stationed on the front platform and passengers used the treadle exits at the center or the rear. This procedure acquainted the public with the features of safety cars, demonstrated that a second man was not necessary and enabled the company to instruct a majority of its trainmen in the use of the new equipment. On June 30, the City Council decided to postpone any action on the proposed anti-one-man ordinance for a period of at least six months. This action provided the company with the desired opportunity to demonstrate the efficacy of one-man service, and, accordingly, two lines were converted on July 4. Other lines were changed as rapidly as possible, and by Aug. 18, one-man operation had been extended to the entire fifteen lines.

Problems in Remodeling Equipment

Many interesting problems attended the conversion of the 101 cars, of which there were five distinct types. Forty cars had double entrance doors in the center and single exit doors in front. Fifteen cars had an extremely small drop platform on the front and a large drop platform on the rear. Twenty-six cars had drop platforms of equal length front and rear, while the remaining twenty, of two different types, had platforms of modern ramp design. All cars were single end, double truck.

The rehabilitation was begun simultaneously at two locations. At the company's main shop, extra carpenters, machinists, painters and electricians were hired. At a second location, where shop facilities were provided, a group of men from the Cummings Car & Coach Company assisted in the work.

It was decided to install every practical modern safety device and to standardize the equipment and controls to the fullest extent. It is worthy of note that all active cars of the company now use the same type of motor, thereby reducing stores and maintenance expense.

Included in the specifications were treadle-operated exit doors, automatic door-reversing mechanisms, ample rubber at sides and bottoms of doors, anti-pinch devices between door leaves, quick release and quick application valves, emergency valves, hand and foot dead-man control, signal lights, inside and outside mirrors and rear-end reverse control. The fare registration system was changed with the advent of one-man service, and new Ohmer registers were installed on all remodeled cars.

Controllers were moved as far to the left as possible and air valves were located approximately in the center, giving ample room for boarding passengers. Copper tubing was used extensively for piping. For convenience in maintaining air equipment, a single compact unit, comprising the quick release valve, emergency valve, double check valve, magnet valve and air contactor, was located conveniently at the front.

From a transportation standpoint, the change-over to complete one-man operation in six weeks presented a huge problem. Previous to the first substitution on July 4, all men had been instructed in the operation of the new equipment. Special supervisors remained with all trainmen until they were deemed competent to operate the cars alone. By beginning operation with comparatively light Sunday riding, operators were enabled to become acquainted with their duties before the weekday rush.

(a)-During this period cash fare was 10 cents, tickets 4 for 30 cents, weekly pass $1
(b)-During this period cash fare was 10 cents, tickets 6 for 50 cents, 1-zone weekly pass $1, 2-zone weekly pass $1.50

During a period when industrial conditions were below normal gross revenue and number of passengers carried have increased as the average fare has decreased

HIGHER REVENUE

With Lower Fares

How a small electric railway has popularized its service by readjusting its rates to meet changed conditions

NOTEWORTHY increases in gross revenue and in the number of passengers carried have been effected by readjusting rates of fare to meet changed conditions in the territory served by one small electric railway. The present average fare is 15 per cent below that of 1919, while the gross revenue is nearly 20 per cent higher. The number of passengers carried last year was approximately 30 per cent greater than in 1919. In the opinion of the management, the success which it has had in building up traffic has been due primarily to the adoption of rates of fare which encourage the use of its service.

For many years prior to 1919 this railway operated on a 5-cent cash fare with six tickets for 25 cents. Under these rates about 75 per cent of the passengers used tickets. War-time conditions necessitated an increase at the beginning of that year to 10 cents cash with four tickets for 25 cents. Thus for the first time a marked differential was created between the fares paid by the casual rider and the regular rider. This differential increased the use of tickets to 90 per cent. The principle of lower fares for regular riders established at that time became the basis of the "merchandising rates" subsequently adopted.

Operating costs continued to rise, however, and in 1920 the ticket rate was increased to four for 30 cents, while the cash fare continued unchanged. This reduced the differential somewhat, but it remained large enough to attract about the same per cent of patrons.

During the next several years the management gave close attention to the subject of fares. It was felt that the users of the service represented three distinct classes: (1) casual riders, (2) intermittent riders, and (3) regular daily riders. Since the riding habit of each class

Total	100.0	100.0	100.0	100.0	100.0	100.0	100.0

was different from that of the other classes, it was thought that each should have a rate of fare suited to its own needs. Meanwhile, automobile competition was having a serious effect upon the railway's traffic. The problem was submitted to the Public Service Commission for its consideration, with the result that authority was granted to charge any desired rate of fare up to and including 10 cents in any one zone.

Three routes are operated by this railway over a total of 12.5 miles of track. Of this trackage approximately a quarter of a mile is common to all three lines, one of which is 2 miles long, a second is 3 miles, and the third, 8 miles. Each of the short lines has a single zone, while the long line is divided into two zones. Four municipalities, with a total population of 22,000, are served.

The first step in adjusting rates to meet the needs of different classes of riders was the adoption of the weekly pass in 1925. This pass, which was valid only on the short lines, was sold for $1. Figures for the year 1925, during which the new rate was in effect for about six months, show that a downward trend in revenue was checked so effectively that the total for the year was about the same as for 1924, while the number of passengers carried increased to a marked extent.

Use of the weekly pass on the short lines aroused a strong desire on the part of the patrons of the two-zone line to have the use of the weekly pass extended to their service. Early in 1926 the management consented to this plan, and the regular $1 weekly pass was made applicable to the first zone of the long line. A universal weekly pass covering all zones on all lines was established at a price of $1.75. At the same time the ticket rate was changed from four for 30 cents to six for 45 cents, it being thought that the necessity to buy tickets in larger quantities would stimulate the sale of its passes. The effect of these changes was to increase both the number of passengers carried and the gross revenue. At the same time the average fare was reduced.

During the latter part of 1929 industrial conditions became seriously depressed in the territory served by this railway and riding began to be curtailed. Another change was then made in the fare schedule, the ticket rate being increased to six for 50 cents and the price of the universal pass reduced from $1.75 to $1.50. While this did not entirely stop the decrease in riding, it was successful in checking it to a considerable extent, as shown by the figures shown in the table below.

During the first seven months of the present year the revenue decreased about 7½ per cent. Cash and ticket revenue decreased greatly, while pass revenue increased moderately. In the opinion of the management this result furnishes good indication of the value of the change in rates.

Advantages of the merchandising fare scale used by this railway are believed to be that it has popularized the company and its service, has brought back to the street cars a substantial amount of traffic which formerly used private automobiles, and has secured the maximum available revenue. Investigation has disclosed that approximately 65 per cent of the pass rides are taken during off-peak hours and only 35 per cent in the rush hours.

Effect of Fare Changes Made in 1929

	7½ Cent Ticket Revenue	Loss	Pass Revenue	Gain	Total Loss
January to June 30 Before Change					
1928	$35,296		$21,302		
1929	33,382	$1,914	21,764	$462	$1,454
July to December 31 After Change					
1928	$34,371		$20,949		
1929	30,924	$3,437	23,934	$2,985	$452

Note—Change in fare scale was from six tickets for 45 cents to six tickets for 50 cents, and three-zone pass from $1.75 to $1.50.

Several methods have been adopted to popularize the pass. During the Christmas holiday week, when many industries are shut down and pass sales would ordinarily decrease sharply, the management adopted the plan of giving away a leather card case in which the pass could be carried. Another method adopted has been to give free passes for the following week to five out of every 100 buyers. Individual pass holders who receive them are selected by drawing numbers out of a hat. Winning numbers and names are published in local newspapers.

Along with its merchandising fare scale, the railway has adopted numerous other means of popularizing its service. It has adopted a new color scheme for its cars, has made innovations in the way of leather upholstery, rubber tile flooring, aluminum fittings, etc. It has also done effective publicity work in a bulletin which it distributes on the cars and in the newspapers of the territory. In the opinion of the management, however, the most important single factor in building up the traffic has been the adoption of the merchandising fare scale.

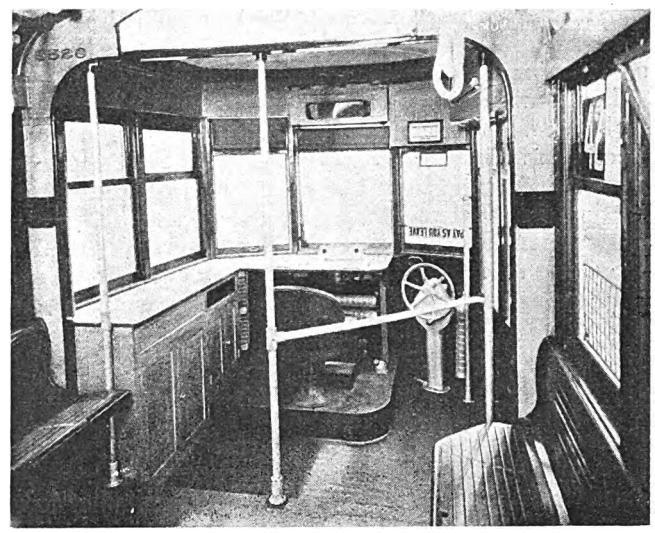
Philadelphia Sample Car

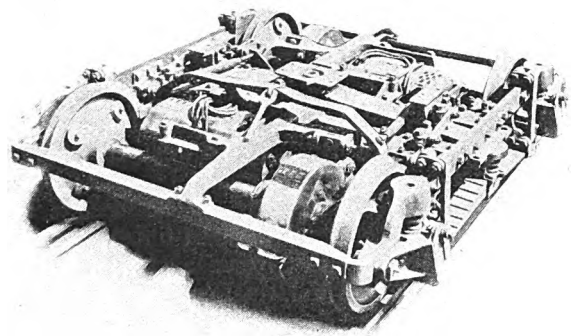
Uses Single-Reduction Drive With High-Speed Motors and Magnetic Brakes

DESIGN of a street car of a new type was undertaken by engineers of the Philadelphia Rapid Transit Company with the purpose of obtaining faster acceleration and braking, placing of more of the operating equipment under a control board and arrangement for efficient operation by one man. In its present form the design of trucks and control equipment has been worked out and the parts have been mounted on one of the existing cars of the company.

The appearance of the front platform is shown in an accompanying illustration. The operator sits on a stool which is secured to a platform raised about 10 in., or the same level as the car floor. The motors and brakes are controlled by pedals, while the doors are controlled by small hand levers which actuate the door engines. Directly in front of the operator, mounted on the control desk, is a panel containing the air-brake gages and signal lights for his information. The electric fare register may be operated either from a lever on the control board or from a pedal at the right of the brake and reverse pedals. The necessary switches and fuses are within easy reach inclosed in a cabinet conveniently placed at the left of the operator's position.



In the sample Philadelphia car the control equipment is assembled in a cabinet convenient to the car operator. Foot control and brake are used.



Single-reduction gearing with a ratio of 7.2 to 1 and flexibly mounted motors are features of the Brill truck used in the Philadelphia car

While the standard exterior painting scheme of bronze green and cream is retained for the exterior, the interior is finished in a light apple green, stippled on a white background, making a very pleasing appearance.

Chief interest in the car centers on the driving and braking equipment. The car is mounted on two Brill No. 84-E trucks which were designed for light weight and to provide sufficient space for mounting a pair of motors with single reduction drive.

Fundamentally the trucks follow standard practice, the bolsters being of cast-steel section with integral pads for center and side bearings and with pockets cast in each end to receive the tops of the coil springs of the graduated spring system. There is a long coil spring imposed between the pocket in the end of the bolster casting and the center of the longitudinal leaf spring, the outer ends of which are supported from the truck side frame through twin link hangers. The forged side frames are modified to take the new compensating wing-type journal boxes. These are attached to drop extensions of the side frames beyond the axles. The boxes are pivotally supported from the side frames by hardened bushed bolts. This reduces the number of parts as compared with the pedestal type, eliminating attendant wear and noise, and producing even shoe wear. The journal bearings are of babbitt-lined brass without wedges.

The truck transoms are of structural steel angles spaced on each end of the bolster and supported from the side frames by flanged gusset plates with driven bolts. End frames of the same material are bolted to projections of the side frames. The wheel-brake rigging is of the conventional type supported on half ball hangers. The shoes are inside hung with a one-piece brake beam. Lubrication is with high-pressure grease fittings. The axles are of the A.E.R.E.A. standard type and are designed to take the single-reduction gear unit. The wheels are of rolled steel of 26-in. diameter. Four silencing blocks of wood are attached to each wheel.

Two unusual features of the truck are a self-contained single-reduction drive made by the Tool Steel Gear & Pinion Company, and auxiliary magnetic rail brakes. The drive consists of a single gear and pinion with a ratio of 7.2 to 1. The gears are made of alloy steel, having spur teeth with a smaller face and pitch than is usual with standard motor drive. This gives sufficient road clearance with 26-in. wheels. The gear is mounted on the axle with plain brass bearings, while the pinion is mounted on roller bearings. Both of these are self-

Digitized by Google

contained in an oil-tight split aluminum housing mounted on the axle and supported at the pinion end by a trunnion link.

The motor equipment on each truck consists of two GE-298-H high-speed motors placed transversely between the axles and the truck transom. These are connected to the reduction gearing through a double universal coupling. On one truck the coupling is made of flexible disks, while on the other truck there is a short shaft with universal joint. The motor and pinion end of the gear unit is flexibly supported from the truck frame by a cast-steel spider extending from the transoms to the end frames on approximately the longitudinal center of the truck, and with extending arms to accept the motor mounting and pivotal end of the trunnion link.

For additional safety during emergency stops from high speeds, the trucks are fitted with magnetic rail brakes located in individual housings over each rail between the wheels and hung from the transoms and transom supporting plates of the trucks. The magnetic shoes when inoperative are carried approximately 1½ in. to 2 in. above the rail. Each is equipped with two air cylinders with spring return and carries the magnet coils for energizing.

The two air cylinders on each magnetic brake are piped together and are connected to a cross pipe which is attached to the top of the transom angle with a connection at the center of the truck to the body air-brake piping. This connection is a looped air hose supported on the truck and body in a manner similar to the motor leads. The air piping is of copper tubing, and by the arrangement described permits equalization of air in all the cylinders.

Dimensions and Weights of Car Trucks

Wheelbase	5 ft. 6 in.
Track gage	2 ft. 2½ in.
Distance between centers of side frames	6 ft. 4 in.
Wheel diameter	26 in.
Wheel tread	2½ in.
Flange height	¾ in.
Flange thickness	1 in.
Size of journals (MCB type)	3¼x7 in.

Weights:	Front	Rear
Four wheels, lb	1,020	1,020
Two axles, lb	712	712
Truck frame, lb	3,486	3,486
Two motors, lb	1,820	1,820
Two speed reducers, including gears, pinions, housings and links, lb	502	502
Two disk couplers, lb	64	85
Magnetic brake guide, lb	160	160
Magnetic brakes and fittings, lb	440	440
Total weight, lb	8,204	8,225
Total weight for two trucks, lb	16,429	

While the magnetic brakes may be used separately if desired, in an emergency application both wheel air brakes and rail magnetic brake are set at the same time. When this is done the stopping distance and time are greatly reduced. In applying the brakes, the first movement of the shoe toward the rail is effected by passage of the air into the cylinders, which forces the shoe within magnetic contact distance of the rail. At the same time the coils are energized and the shoes are pulled to the rail, by magnetic attraction, the remaining distance of ¼ to ⅜ in. The magnetic drag of the shoe on the rail lasts for a predetermined time, with automatic release by cutting off the current to the shoe, which then returns to its original position through the pressure of piston springs.

Washington Experiments with Street Markers

WHITE rubber insets are the latest of a number of devices to be tried by the Washington Traffic Bureau with the aim of developing a satisfactory traffic lane marker. Two street corner installations of this kind have just been made at busy intersections for test purposes. The insets are in the shape of a rectangular box with slanting sides, 3 in. wide by 2 ft. long by 3 in. deep, the depth apparently being made to conform to the average 3-in. depth of asphaltic pavings. The rubber box is filled with asphaltic material similar to that of the paving and bedded in a trench cut in the road. Additional paving material is placed around the edges of the inset, to present a smooth surface. Holes are provided in the sides of the box through which the filler material may bind with the roadbed asphaltum.

Though the insets appear to keep their white surface characteristic and are expected to be as permanent as the roadbed in which they are incorporated, the disadvantages of an expensive installation and a somewhat disrupted paving surface are attached to their use. As the asphalt filler material cannot be compressed to the same density as the pavement, it is believed that the action of trucks and heavy vehicles constantly crossing it will press it below the level of the pavement. A cold asphaltic concrete filler was first tried out in a coarse aggregate pavement, with indifferent action. Better results were obtained with hot sheet asphalt. Another objection, which also applies to Monel metal buttons, is that they constitute a permanent installation at some expense which would be totally lost when the roadbed is to be replaced. Such replacement occurs at the rate of 300,000 sq.yd. annually in the District of Columbia.

White paint of the latest specifications furnished by the Bureau of Standards has proved itself a cheap and practical means of marking, except when paint machines are to be used. Paint probably will be extensively utilized for many years, being gradually replaced by more permanent marking. Specifications call for approximately 20 per cent zinc oxide, 65 per cent lithophone, and 15 per cent other paint pigments, mixed with thin varnish. These proportions give a brilliant and durable white finish, which dries within an hour. The paint, however, is somewhat sticky for machine use.

Strips of white canvas on rubber mat backings were tested in the effort to find a practical and permanent form of marker. It was found that insufficient traction was exerted by the rubber mats to hold the canvas in place, resulting in large sections of the marker being torn up by the sudden braking of wheels, or being distorted into zig-zag lines.

Another device tried was a patented white cement filler, somewhat similar to "roadrite," which was placed in a shallow trench dug right along the lines of a cross lane. This material depressed below the level of the pavement and discolored within a week.

Despite continued experiments with other forms of guides, Monel metal buttons have thus far proved to be the most satisfactory traffic marker, according to M. O. Eldridge, assistant traffic director. They will be installed on cross lanes throughout Washington as fast as funds allow. Traffic plans contemplate the installation of the buttons and metal strips on some of the main boulevards, and, eventually, in parallel lanes to aid in the elimination of traffic weaving.

CO-ORDINATION OF TRANSIT FACILITIES

Proposed for St. Louis

Special commission recommends that one management run all car and bus lines. Improvements that can be made in surface transportation should defer the need of rapid transit for some time.

FOR the past two years a transportation survey commission, created by the City Council of St. Louis in June, 1928, has been investigating conditions covering all phases of transportation, traffic and matters related thereto in the city. Specifically included in its duties were investigation of general street and highway plans and related matters; mass and public transportation, including rapid transit, street railway and bus service; taxicabs and service cars; the ways and means whereby the co-ordination and operation of such transportation facilities shall be brought about and covered for the benefit of the public, and relief of general traffic congestion. E. J. Russell, of Mauran, Russell & Crowell, architects, was appointed chairman of the commission. The Mayor, other prominent city officials and business men, including one of the state public service commissioners and the president of the St. Louis Public Service Company, were members.

The commission selected Kelker, De Leuw & Company to conduct the actual survey. This firm submitted eleven reports. These included plans for improving and co-ordinating existing transportation facilities; a rapid transit plan; a detailed survey of traffic conditions; and drafts of several tentative ordinances and legislative bills for consummation of the plans.

When the commission was created there was a widespread belief in St. Louis that rapid transit was necessary immediately. Accordingly, the first investigation was that of a system to comprise (1) high-speed radial rapid transit lines with limited stops for long-haul traffic; (2) local street railway lines feeding the rapid transit lines, and (3) local motor bus lines serving as feeders to street cars and rapid transit lines and providing extensions in sparsely settled districts.

At the outset, the consulting engineers recommended that one company should acquire and operate all of the existing local subways and elevated structures. Further study showed that many advantages would result if all local transportation facilities could be co-ordinated and operated under one management. Since in an extended program for improvements and additions the problem of financing becomes of paramount importance, it was decided to base the unified transit system upon a terminable permit with necessary safeguards.

Financing of rapid transit lines presented additional difficulties. It was pointed out that elevated railroad construction requires about 25 times the capital necessary for street car tracks, and subways approximately 50 times as much. Accordingly, if the entire cost of rapid transit structures is to be borne by the car rider, the portion of his fare necessary for fixed charges would impose an undue burden on him. As a result of the studies, it was concluded that when rapid transit lines in St. Louis are built they should be financed in part by special assessments.

A survey of the street railway service convinced the engineers that it is susceptible of many improvements, making it possible to defer expensive rapid transit construction. Checks of the actual running time showed that some of the causes for the slow movement of street cars were narrowness of the streets, parking of automobiles, density of traffic on intersecting streets, short distances between street intersections, old type cars requiring too much time for loading and unloading, and too many stops.

With the majority of the lines of the Public Service Company equipped with cars suitable for mass transportation, with stopping places reduced to an average of eight per mile (660 ft.), with more direct routes in the intermediate and outlying districts, and with improved routing downtown, it was held that the running time could be materially reduced and kept within a reasonable time for travel to and from business or employment for a number of years to come.

Changes in routing of several of the street railway lines were recommended at an estimated cost for new tangent track and special work of $726,000. Left turns would be reduced 82 per cent by the proposed routing.

Street Car and Bus Co-ordination Urged

Following up their theory that so many improvements could be made in the existing transportation facilities as to defer the necessity for rapid transit facilities, the engineers submitted a plan for the co-ordination of street railway and motor bus service. Wasteful duplication of service was found in many sections of the city. In the rush hours, the bus company does not satisfy the demands, and the overflow traffic must be handled by street cars. For this reason, the number of cars in the rush hours is more than three times those during the non-rush. This has an important and direct bearing on the rate of fare. The street cars were found to maintain a more frequent service, and although on the average they handle more than twice as many passengers per vehicle-mile as do the buses, their average speed is equally fast.

Because of their flexibility, the engineers believe that

Digitized by Google

buses can be used to advantage to provide radial express service within about 3 miles from the business center. In general, the plan proposes that, where an existing street car route closely parallels an existing bus route, the bus line should be abandoned or changed to express service. Where express service is to be furnished by motor buses, the existing equipment should be used only until more suitable buses can be substituted.

It was generally agreed by the commission that new capital must be obtained for any major improvements. This flow of capital to St. Louis will likely be determined largely by the terms and conditions under which the several companies operate. Accordingly, an ordinance was drafted by the engineers incorporating the fundamental principles of service at cost. Under this the company would be allowed to charge to the cost of the service: (1) operating expenses, including taxes; (2) payments into authorized reserve funds; (3) a fixed return on the initial capital value, which would be equivalent to the city purchase price; (4) a return equivalent to the cost of money for extensions and additions; (5) compensation to the city; (6) compensation to the company. Any surplus would form a barometer fund.

Compensation received by the city might be used: (1) to acquire any bonds represented in the initial capital value; (2) to purchase any extension bonds at par on issue; (3) to commute fares by paying any deficits arising from operation into the barometer fare fund, or any other agreed method.

The city and company, by agreement, would determine the following items for insertion in the ordinance, subject to any necessary approval by the state commission: (1) initial capital value; (2) initial rates of fare; (3) initial percentages of gross receipts to be paid into the reserve fund; (4) appointment by the Mayor of a transit commissioner with general supervision over the operation and accounting of the company; (5) co-ordination of the city and suburban services furnished by the company. The recommended term of the franchise was 50 years—the maximum provided by the city charter—with provisions for renewal and with an option for the city to purchase before that time.

A report on the transportation needs of St. Louis covered the possible improvements in the transportation facilities, traffic regulations and street system. These improvements, the engineers estimated, would require capital expenditures of about $23,800,000 during the succeeding five years.

Five recommended methods of obtaining faster, more comfortable and more convenient street railway service included a comprehensive re-routing, a reduction in the number of stopping places, purchase of modern cars, installation of additional feeder bus lines, and extensions of street car lines.

At present there are about 1,350 street cars on the system, of which only 250 are modern. It was recommended that approximately 800 modern cars be substituted, especially on the lines running into or through congested areas, 400 for replacement of present equipment and the remainder as additions. Purchase of these would involve a capital expenditure of about $12,800,000. Car line extensions on six streets were recommended at a cost of about $1,338,000. Fifty buses were recommended as additions to the present feeder bus lines to serve districts of the city not now adequately served. The estimated cost, including garages, was about $512,000. All these expenditures for improvements should be spread over five years, $4,800,000 in each of the first three years, and $4,700,000 in each of the last two.

Between 350 and 400 "service cars," which are private automobiles carrying passengers for hire, operate over approximately 50 route-miles, and charge fares from 15 to 25 cents a person. The engineers found many objections to their use and recommended the substitution of small, high-speed, de luxe buses.

Studies of a rapid transit plan indicated that subways for street cars in the business district would not provide traffic relief in keeping with their cost, would be of little benefit to street car patrons, and other and less costly means of traffic can and should be employed to the fullest extent. A comprehensive rapid transit plan to meet future needs should be adopted now and be constructed as and when any of the routes are necessary and can be financed. Rapid transit structures preferably should be located under or upon wide streets or highways which have space for such structures, thus obviating the expense of procuring a private right-of-way.

Rapid transit lines proposed for future construction, all double track, include (1) a line from the city limits along Manchester Avenue, Chouteau Avenue, Broadway, Cass Avenue and Easton Avenue to the city limits; (2) from the city limits along Gravois Avenue, Ninth Street, Fourteenth Street, Twentieth Street and Florissant Avenue to the city limits; (3) from the city limits along Delmar Avenue and Olive Street to a suitable terminal east of Third Street; (4) from a connection with the Gravois Avenue line along Compton Avenue and Michigan Avenue to Tesson Street.

It was estimated that if these lines were all constructed as subways, the modified plan, as proposed by the engineers, would cost $214,331,000. If subways were used extending to the outer limits on the first and second step proposed in 1926, with elevated structures beyond that, the total cost would be $144,929,000, and if subways were used to the outer limits of the first step only and elevated beyond, the total cost would be $87,052,000.

For traffic regulation and control the installation of traffic signals at 90 intersections in the business district and 88 in the intermediate and outlying districts was recommended at an estimated cost of $279,000. One hundred safety zones of the concrete platform type and upward of 200 of the metal mushroom type were proposed at an estimated cost of $65,000. Prohibition of parking in the business district during business hours is inevitable, states the reports.

Besides the reports of the commission's engineers, several communications from others are included. Stanley Clark, president of the St. Louis Public Service Company and a member of the commission, proposed immediate construction of street car subways in the downtown district. Two plans of re-routing cars are also proposed. In general, these recommendations are along lines similar to those of the commission's engineers.

Widening of a number of existing streets and construction of some new streets in and adjacent to the present business district are recommended. It is proposed that some of the streets, particularly near the river, be double-decked. It is stated that the plans, as proposed, will stop shifting of the business district, stabilize property values at its eastern end, and assist traffic circulation throughout the city.

Minority reports were presented by two members of the commission. Both of these members dissented principally from the idea of granting a terminable permit to the operating company. In practically all other matters these two members concurred in the report.

Although Public Service Co-ordinated Transport operates more than 500 buses in Newark, it continues to operate approximately 450 electric cars. Company officials estimate that 1,000 additional buses would be required to take the place of these cars, and believe that the consequent congestion would be intolerable

How Public Service Co-ordinated Transport uses buses to supplement and extend rail service and to replace single-track lines. In larger cities the electric car remains the backbone of the system. This article is based on a paper recently presented before the Transportation Group of the New York Section A.I.E.E.

Development of the Bus for

Mass Transportation

By

A. T. WARNER

General Manager in Charge of Traffic

Public Service Co-ordinated Transport, Newark, N. J.

STREET car operating men, who were brought up on the theory that public transportation must be safe, are largely responsible for the rapid development of the motor-driven bus. When the vehicle was first placed in their hands as a medium to care for their patrons, its safety was so questionable, the operation was so uncertain and unstable, that they demanded of the manufacturers and automotive engineers immediate developments which would make the bus a safer vehicle for the highways.

The bus of 1922 was a far cry from those which we are placing on the highways today. It was a truck chassis with a passenger body on it. It had a four-cylinder motor which was designed for truck use and totally unfit for the frequent stops and starts, the high acceleration desired, and other characteristics inherent in bus operation. Many of the vehicles were equipped with hard tires, and even pneumatics were high-pressure and single in the rear; the body was high, with three and sometimes four steps; springs were such that there was a "kick-up" toward the rear; seats were uncomfortable and narrow, and there was no adequate light, heat or ventilation. If the weather was wet, pavements slippery or icy, these vehicles were positive menaces on the highways.

We all realized that our first duty was an immediate change in chassis design to lower the center of gravity

Digitized by Google

and to create a safer vehicle. This meant an entire change in spring arrangement. These were underslung, and auxiliary leaves were introduced to care for the variable load factor. About the same time, dual tires for the rear axle were introduced. This went a long way toward establishing safety by reducing skidding. The manufacturers started to design engines for bus use and adopted the six-cylinder motor. The lowered chassis immediately allowed an increase in length and, consequently, in seating capacity, and success with the six-cylinder engine has increased horsepower from the 40 hp. engine of 1923, to those of 150 and 180 hp. which are being used today.

In 1925 the gas-electric hook-up was first started experimentally and proved an immediate success. We are now operating approximately half of our fleet of 2,500 with gas-electric buses. We use them entirely for city service in congested areas and for low-speed work. We believe them superior in this type of service, both from the point of view of the operator, the passenger and the maintenance department. City service with us means a speed of 8 or 9 m.p.h., depending upon congestion. It means that there will be ten stops per mile.

Every operator, therefore, in the course of nine hours' work, would be compelled to make 3,600 motions with his gear shift lever, if he was driving a gear shift bus, and these 3,600 motions would only include passenger stops, and not traffic delays, slow-ups, or signals. Of these 3,600 motions, three-quarters of them are in process of acceleration. There was, therefore, a tremendous temptation always confronting the operator to start in second or third speed, abusing the clutch, jerking the passengers and damaging the equipment. Before we went to gas-electric operation approximately 80 per cent of our road failures in city service resulted from trouble back of the motor. The gas-electric drive eliminates the gear shifting and is consequently not only a great benefit to the operator, but gives the passenger a smoother and more comfortable ride and creates, we believe, a saving in maintenance. We have confined our gas-electric operation entirely to city service where a large number of stops per mile is the main factor to be considered.

As we have progressed in the improvement of the chassis, engine and driving mechanisms, we have, likewise, been able to produce a better body, and have been supplied with seats and other accessories constantly improving in comfort, rider appeal and performance. Tire development is only one example of this. In common with many other large companies, we do not buy any tires, but tire service on a mileage basis. Our first tire contract showed an average mileage per tire of approximately 8,000 miles. We now have balloon tires on practically our entire fleet, and this year our tire mileage will be approximately 25,000 miles per tire—a 300-per cent improvement in the course of six years, certainly a wonderful record. For this we have the energy, research and ability of the tire manufacturers to thank. In the same way, lighting, heating and improved ventilation have come about, as a result of infinite tests, care, patience and money. The bus we are putting on the streets today is a vehicle as safe, as comfortable, and as fast as a private automobile, and it is because of these factors that the bus has taken its present position in the transportation field.

In 1923, which was the first year of our bus operation of any magnitude, we operated 500,000 bus-miles, carried approximately 2,000,000 passengers, and ran at a speed of 8 m.p.h. Last year, 1929, we operated 82,000,000 bus-miles, carried 344,000,000 passengers, and our speed was 10.5 m.p.h.

From an operating point of view, the advantage of the bus is its complete flexibility. There is nothing to hold the bus to either a fixed position on the street or to a fixed route. In case of congestion, fire, disturbance of any kind, the bus can be rerouted either around an adjacent block or to a larger extent. Express service can be installed by taking loaded equipment off congested thoroughfares and expressing them via the fastest possible route. Curb pick-up and delivery is another important item of service to the shippers that has popularized the motor bus.

We are very firmly of the opinion that in our larger cities, where mass transportation and street congestion are important factors, the operation of electric cars on rails must still be considered as the backbone of local transportation. Buses can be used in many ways to co-ordinate with this service; to supplement it; to extend it; to tap new areas; to furnish new crosstown services; to replace single-track trolley operations and to furnish de luxe service at a higher fare. But the development of the art has not yet reached the stage when bus operation can supplant entirely the electric car. In some of our smaller cities such as Paterson, Passaic, New Brunswick, Elizabeth and Plainfield, our local service is now practically 100 per cent bus operation, but in larger localities car operation is still necessary. Altogether, we have replaced car service on approximately 150 miles of single-track, but we have not abandoned a single mile of double-track car line. In Newark, although we are operating over 500 buses, we are still running approximately 450 trolley cars, and if these 450 cars were to be removed, more than double that number of buses would be required to take their place. I doubt if the imagination can picture Broad Street with 1,000 more buses on it at 5 o'clock at night than there are today.

We are very firmly of the opinion that in our larger cities, where mass transportation and street congestion are important factors, the operation of electric cars on rails must still be considered as the backbone of local transportation. Buses can be used in many ways to co-ordinate with this service; to supplement it; to extend it; to tap new areas; to furnish new crosstown services; to replace single-track trolley operations and to furnish de luxe service at a higher fare. But the development of the art has not yet reached the stage when bus operation can supplant entirely the electric car.

RELIABILITY

Features Reading's Power Supply

By C. L. DOUB
Assistant Engineer, Reading Company
Philadelphia, Pa.

INITIAL plans for the Reading electrification authorized in 1928 included only suburban lines within a radius of about 25 miles from Philadelphia on four branches, with the view that it was the beginning of a program of more comprehensive scope. During 1930 extensions were authorized to Doylestown and to West Trenton, respectively about 35 miles and 33 miles from Reading terminal. These additional authorizations bring the total up from the original 50 miles of route and 120 miles of single track to 69 miles of route and 161 miles of single track. Five miles from Philadelphia to Wayne Junction has four tracks, the Doylestown and Hatboro branches are principally single-track, and the remainder is principally double-track. East of Neshaminy Falls is also principally four-track, and all are being electrified.

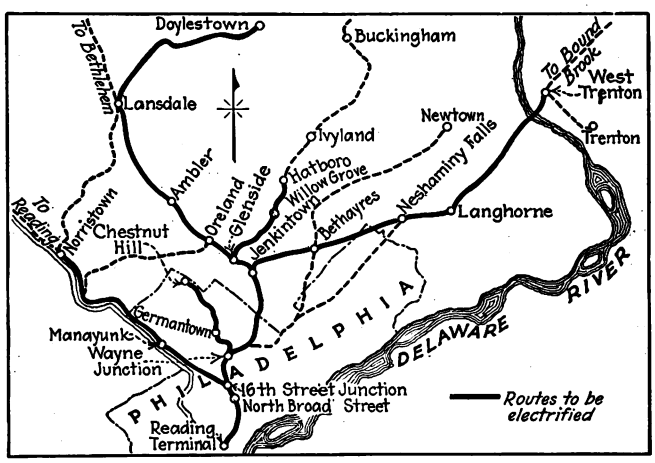
Since the ultimate plan is to electrify through passenger and freight service, designs are being made for all classes of trains in the present electrification so that the system can be extended readily at any time without material changes in the present power supply, excepting as to additions of equipment. These plans include possible electrification to New York, Bethlehem, and Reading, involving some 250 route-miles and about 1,000 track-miles including yards and sidings, which may be served with power from the Philadelphia area.

The single-phase alternating-current system, with nominally 11,000 volts on contact wires and with actual design for 12,000 volts, is being used.

The power and substation layout was based on one source of supply at Wayne Junction, about 5 miles from Reading Terminal, near the electrical center of the Philadelphia load. Adequate property was available, and the location is at an advantageous junction point for the railroad lines, and situated favorably as regards other railroad operating facilities. It is also advantageous for the Philadelphia Electric Company, from which the power will be purchased, being close to its principal Philadelphia load center. The power company is providing at Wayne Junction a 60-cycle to 25-cycle frequency changer station exclusively for the railroad load. This station will have initially two 15,000-kw. 70-per cent power factor, 21,400-kva., motor-generator sets and space for six such sets with an ultimate total installed capacity of 90,000 kw. and 128,000 kva.

The railroad substation at Wayne Junction will receive power from the power company at 13,200 volts, 25 cycles, single phase, where it will be transformed and distributed to the railroad's contact system and transmission lines.

Due to the heavy traffic density on the Reading company trackage, which is used jointly for suburban, through passenger, freight and switching purposes, the greatest flexibility of train operation must be provided. An unusually large number of interlocking plants permit the most flexible use of tracks, and it was considered necessary to provide sufficient sectionalizing of contact lines that this flexibility in use of tracks would not be impaired by the electrical system. The location of these

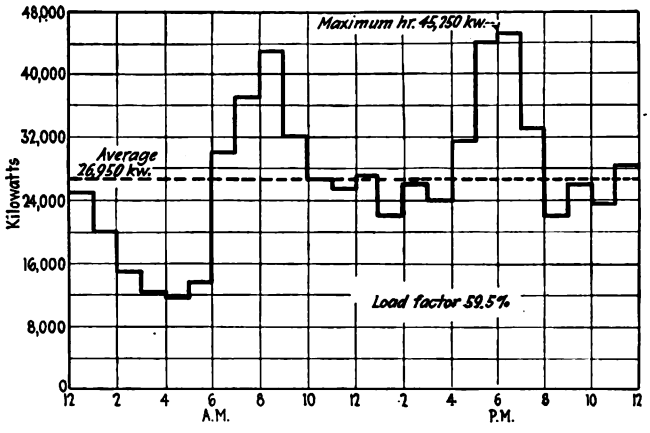


Recent authorizations have extended the Reading electrification to include 69 miles of route and 161 miles of single track

interlocking plants and junctions of the various branches made it advisable to install switching stations with complete automatic protection at intervals of approximately 6 miles, regardless of power transmission or voltage regulation requirements, and it was considered advisable to make these stations complete substations by the addition of transformer equipment. There would be further advantage of substations at comparatively close intervals in reducing the total induction from the electrical system.

For the initial railroad power installation it was decided to use the three-wire system with a superimposed high-voltage transmission line to serve future extensions into more remote territory. The voltages chosen for the three-wire system were 12,000 between trolley and rail, 24,000 between "feeder" and rail, and 36,000 between trolley and feeder. The two-wire, single-phase transmission line would be 66,000 volts. Electrification beyond the initial territory could be carried out by using additional three-wire distribution fed from one or more outlying points through suitable stepdown transformers. These transmission lines become simple lines from Wayne Junction to one outlying feed point on each branch, with a minimum of high-voltage switching equipment.

Digitized by Google



Estimated weekday loads for the electrification when extended to Bound Brook, Bethlehem and Reading will reach an hourly maximum of 45,250 kw. in winter

The arrangement permits tapping the 66-kv. lines at any desired intermediate points to augment the three-wire system through so-called "three-winding" or tapped-secondary transformers, should the growth of the electrical loads make it desirable. Space is being reserved at certain of the initial intermediate substations so that at any time they may be readily extended to become such step-down substations with small additional cost.

Substations for the initial electrification will have installed capacity as follows:

Substation	Transformers Number	Transformers Kw. Each	Substation	Transformers Number	Transformers Kw. Each
Reading Terminal	3	2,000	Bethayres	1	2,000
Wayne Junction	3	8,000	Neshaminy Falls	2	2,000
Jenkintown	2	2,000	Yardley	2	2,000
Ambler	1	2,000	Chestnut Hill	2	2,000
Lansdale	2	2,000			
Doylestown	1	2,000	Total	3	8,000
Hatboro	1	2,000	Total	17	2,000

Low-reactance auto-transformers of 2,000 kva. are used excepting at Wayne Junction, where 8,000-kva. transformers step up from 13.2 kv. (generator voltage) to trolley-rail voltage of 12,000 and trolley-feeder transmission voltage of 36,000. All transformers are nominally rated with 50 per cent overload for two hours, and 300 per cent for five minutes. Both types are oil-insulated, self-cooled.

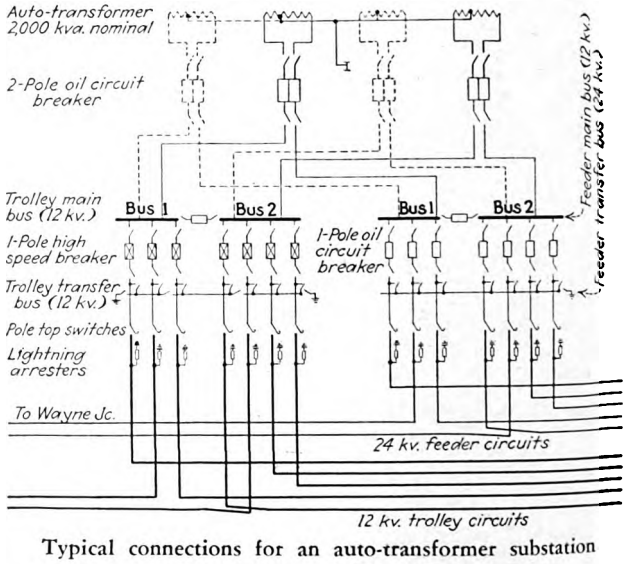
All contact lines in each direction from each substation are fed independently by high-speed circuit breakers. Duplicate feeders at 24 kv. to ground are installed along each portion of the route, excepting the single-track branches, with oil circuit breakers serving each end of each feeder. The substations are, therefore, switching stations for all feeders as well as all trolley circuits.

The typical station includes a single-conductor trolley bus and a single-conductor feeder bus, each serving the respective outgoing lines and each being fed through two-pole breakers from the auto-transformers at that station. The most important stations include automatic oil circuit breakers for sectionalizing each bus, with additional remote manual-operated disconnecting switches for further localizing trouble in these buses. The remainder of the stations have remote manual disconnecting switches only in the bus, but if desired, oil circuit breakers may be installed later for bus sectionalizing. Each bus or bus section has automatic differential protection against faults on the bus or immediate connections. This locks out all breakers connected to that section of the bus but to allow restoring service immediately if the trouble clears itself, these lock-out relays may be reset through the supervisory control system.

Further flexibility in switching of lines and maximum operation without stub-end feeds are made possible through a transfer bus for each trolley and feeder bus with remote manual-operated disconnecting switches for each outgoing line and transfer bus sectionalizing switches. These will be used for routine breaker and bus maintenance as well as in case of trouble. This bus may be used to connect any two lines together to feed from one circuit breaker, or, by use of transfer bus sectionalizing switches, may connect more than one of such pairs in certain combinations. With this grouping of the outgoing lines, de-energizing a section of the main bus will de-energize only one track or one feeder in any territory. Also when a main bus is out, all lines served by that section can be grouped through the transfer bus to be served by other breakers in the station so as not to impair the relay protective scheme. The transfer bus for the feeder is somewhat less necessary than for the contact lines since a main bus outage will not kill all transmission lines in one direction. This transfer bus will, however, permit the maximum use of the feeder transmission copper in the event of bus or circuit breaker troubles or during routine maintenance. Ground switches are being installed upon the transfer buses so that they may be used also as ground buses under certain special conditions.

Outgoing lines are all provided with horn-gap disconnecting switches on the substation terminal structure so any connections within the substation limits may be de-energized for working purposes. Lightning arresters are being installed upon the terminal structure, connected at the line side of the switch through "live line clamps" to permit them to be disconnected readily. Remote manual group-operated disconnecting switches isolate each circuit breaker.

High-speed circuit breakers feed all trolley circuits. Both oil and air-type circuit breakers have been developed for 12,000 volts within the last several years and have been thoroughly tried out in heavy-duty service. The circuit breaker chosen was the General Electric JRA-32 air-break high-speed type with a rating of 1,500 amp. continuously at 15,000 volts, 25 cycles. This breaker has a single-pole interrupting capacity of 50,000 amp. at 12,000 volts, and is specified to perform 50 "OCO" duty cycles consecutively at two-minute intervals as compared to the usual rating of only two "OCO" duty cycles which

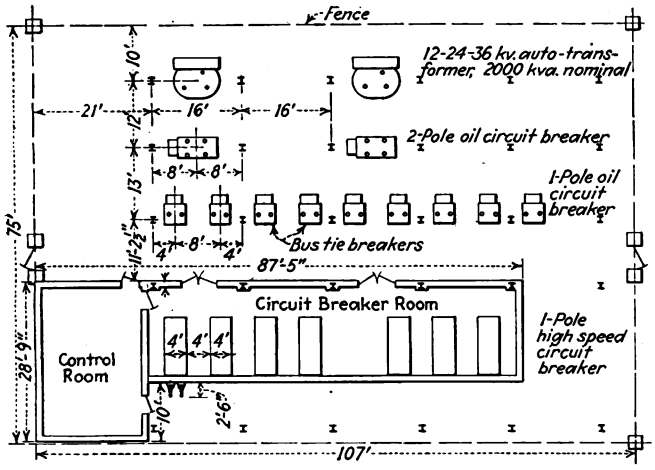


Typical connections for an auto-transformer substation

Digitized by Google

is standard for the normal oil circuit breaker. Its principle is the so-called "impulse tripping" on short circuits depending on the rate of change of 25-cycle current from one half cycle to the next. It is a development of the indoor type of breaker, although it can be arranged for outdoor mounting by the addition of suitable weather-proofing covers.

The control and breaker building is laid out parallel to the main tracks and at one edge of the substation. An adjacent parallel bay of the outdoor substation provides for the single-pole feeder breakers serving the outgoing 24-kv. lines and also single-pole breakers of the



The auto-transformer substations include outdoor high-tension equipment with indoor circuit breakers

same type which are used as bus tie breakers. The next parallel bay provides for the two-pole transformer breakers connecting transformers to trolley and feeder buses, beyond which is the transformer bay along the opposite side of the auto-transformer station. Single-pole feeder breakers and two-pole transformer breakers are all outdoor oil breakers of the newly developed Westinghouse "deion grid" type. Outgoing lines may be taken out at either side of such a substation and the substation located most advantageously for the use of a siding or of main line tracks along one side from which to handle the transformers.

In order to simplify design and maintenance, a unit type of construction was adopted for auto-transformer stations so that all stations will be similar except for the number of units required for the varying numbers of transformers and outgoing lines. The typical unit consists of a 16-ft. section containing two trolley breakers, two feeder breakers, one transformer breaker, and one transformer. A particular station includes the necessary number of units with such items of equipment in each unit as are required. Trolley and feeder breakers are each located on 8-ft. centers and are so connected that the corresponding outgoing lines are staggered and are run parallel and horizontal, with 4-ft. spacing, to a feeder structure over the tracks opposite the substation location. Connections to lines at the feeder structure are made by taking vertical leads upward to 24-kv. feeder lines and downward to the catenary system.

The resultant layout is compact, simple and clear. The space requirements and over-all height are moderate, but electrical and working clearances around apparatus and connections are liberal.

The portion of the main station supplying trolley and feeder lines at Wayne Junction follows the same unit design as for auto-transformer stations, with exactly the same arrangements and spacing of apparatus. There is added, however, a section of station for primary power supply to the transformers, which is not necessary for auto-transformer stations. This extension includes a bay for primary 13.2-kv. double-pole circuit breakers adjacent to the transformer bay, beyond which are two bays for the 25-cycle, 13,200-volt ring bus with generator and bus sectionalizing breakers, future bus tie reactors, etc.

The ring bus is single phase. Space is reserved for a third conductor to be added to change to a three-phase bus should parallel operation of frequency changer units in the future make this desirable in order to hold these machines in synchronism. The bus is designed for an ultimate of six sections of ring, each to be served by one 15,000-kw. frequency changer set and each section to feed two 8,000-kva. transformers, one with three windings for the three-wire distribution system and the other to step up to serve the 66-kv. transmission lines. Complete automatic protection would be provided for each bus section and additional short circuit limiting reactors would be installed at several points in the bus for connection when all machines were operating. The initial portion of the station will include only a portion of the ring bus, so arranged so as to provide three sections in straight line, each feeding one 8,000-kva. transformer, and the end sections being fed by the two frequency-changer units installed initially.

The initial Wayne Junction station serves ten outgoing contact lines and six outgoing feeder lines. As additional tracks are electrified, it is planned to extend the three-wire portion of the station to serve twenty outgoing 12-kv. trolley lines and eighteen outgoing 24-kv. feeder lines, and to make a further extension of the station to provide a 66-kv. section containing a possible ultimate of seven 8,000-kva. step-up transformers, bus, and eight double-pole 66-kv. breakers for duplicate outgoing lines toward Bethlehem, New York, Reading, and the transmission system of the Baltimore & Ohio Railroad, all as and if required. The 66-kv. transmission lines toward New York can be extended to connect with the system of the Central Railroad of New Jersey, over which the Reading Company has trackage rights between Bound Brook and Jersey City, its New York terminus.

The Wayne Junction substation building includes a two-story control house, the second floor of which will be load dispatching headquarters for the entire electrical system. A supervisory control system is provided for the operation of all of the present substations, none of which will be attended, and the load dispatcher will directly control all circuit breakers, motor operated disconnecting switches, etc., from an operating desk. The layout is made for future extensions to cover all of the through passenger and freight territory above referred to, if it is desired to perform this operation from the Philadelphia headquarters. The railroad load dispatcher will be in close telephone communication with the railroad train dispatchers and also with the load dispatchers and operators of the Philadelphia Electric Company system supplying the Reading company.

The control buildings for all substations will include switchboards for control and protection of all lines, storage batteries and charging equipment, and supervisory control equipment operated directly from the Wayne Junction load dispatcher's headquarters, together with the maintenance and inspection facilities required.

More Power

By

J. W. WELSH

Assistant to the President, Cleveland Railway

Motors of radically higher horse-power are needed. Efforts to reduce energy consumption may be false economy. Possible savings in transportation expense resulting from higher speeds are greater than the added power cost

AUTOMOTIVE engineers have not been afraid to use power freely, even extravagantly, to secure pre-eminent performance, while electric railway engineers have bent every effort to use as little power as possible. As a result, the automobile has outstripped the electric car in acceleration, maximum speed, and in the general flexibility of its operation. American automobiles compared with foreign types have admittedly employed larger engines and faster gear ratios, partly because gas is cheaper and taxes are lower here, but more than anything else, because the *sine qua non* of motordom today is power. A speed margin of 5 per cent has satisfied electric railway engineers in applying motors to cars, while the automobilist has had held before him the thrilling possibilities of a speed margin of many hundreds per cent. What the electric car needs is more torque, continuously, uniformly and copiously available from rest up to the maximum operating speed.

Our researches in the direction of increasing speeds should take nothing for granted. The characteristics of the series motor, admirable as they are, have some notable deficiencies. It is true that, during the first part of the acceleration period, while running on resistance up to the point of applying full voltage to the motors, the series motor is an effective torque machine. During this period, the acceleration may be made as rapid and smooth as conditions will permit. But as soon as the resistance is cut out, the car speed crawls lazily up along the gradual slope of the motor curve at a most aggravatingly leisurely pace.

We talk about gearing our cars in city service for free running speeds of 30 m.p.h. or more, and yet, in frequent stop service, it is rarely possible to attain over half these speeds. Even if we do, we have employed a time wasting process during the latter part of the accelerating period. Thus, in a typical case with an initial accelerating rate of 2.5 m.p.h.p.s., 12.5 m.p.h. is attained in five seconds; but it takes 100 seconds to attain the free running speed of 28 m.p.h. This is illustrated in the typical performance curve shown in an accompanying chart.

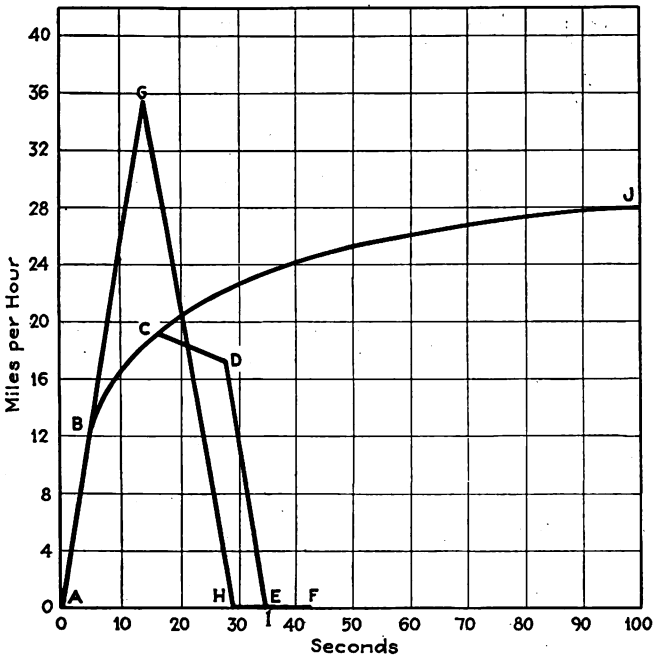
The reason for this sluggishness in acceleration after the resistance notches are passed is that the torque is being gradually reduced as a result of the weakening of the field. This follows the reduction in current due to increasing counter electromotive force as the speed increases. Further, the free running speed may be increased by weakening the field by the reduction of current in the field windings, by shunting the current around them, or by cutting out a part of the turns. In any case, a higher speed, it is true, is secured, but at a relatively low rate of acceleration. And the reason is that acceleration is proportional to the torque, and the torque is low because of the weakened field.

With the present characteristic in the design of series motors and present methods of application to service, undoubtedly an advantage accrues in many cases by using field control to attain higher free running speeds, and there is no question about its being an electrically efficient method. The objection is the slow rate of acceleration and loss of time that accompanies its use.

In frequent-stop city service the time cycle is, at best, all too short. In the past it may have been satisfactory to handle a service calling for, say, seven stops per mile, with a cycle of 42 seconds, approximately five seconds on resistance points, eleven seconds creeping up on the motor curve, twelve seconds coasting, seven seconds braking, and seven seconds standing. Such a cycle is shown at *ABCDEF* in the diagram. Elimination of the coasting will cut the duration of the run only slightly.

If maximum acceleration can be continued until the current is cut off at a considerably higher maximum speed and the brakes are applied immediately, as at *AGHI* a far higher schedule speed is possible. Obviously, such a cycle demands a material increase in motor horsepower and in energy input.

Digitized by Google



Speed-time curves for normal and suggested operation

Service: 7 stops per mile — 2.5 m.p.h.p.s., braking
7 seconds per stop — 2.5 m.p.h.p.s., acceleration

Beginning with the typical cycle *ABCDEF,* the run of $\frac{1}{7}$ mile would be made in 42 seconds. In the fast run, *AGHI,* the same initial acceleration, 2.5 m.p.h.p.s., would be continued up to point *G* at 35.5 m.p.h. Then power would be cut off and the car stopped by the brakes at the same retardation rate of 2.5 m.p.h.p.s., at the end of 28.5 seconds, reducing the total time for the run, including the seven-second stop, to 35.5 seconds. The schedule speed would be 14.5 m.p.h. against 12.2 m.p.h., a gain of 19 per cent. This material gain in schedule speed would involve changes in energy consumption as shown in the following table:

	Ordinary Equipment		High-speed Equipment	
Maximum speed, m.p.h.	19.4		35.5	
Speed at cut-off, m.p.h.	12.5		35.5	
Maximum power per motor, kw.	46.2		131	
	Ft.-Lb.	Per Cent of Total	Ft.-Lb.	Per Cent of Total
Maximum kinetic energy per ton; foot-pounds ($\frac{1}{2}MV^2$)	25,500	56.4	85,000	51.4
Rotational energy, 5 per cent	1,275	2.8	4,250	2.6
Car resistance	7,540	16.6	11,310	6.8
Rheostatic loss	6,000	13.2	48,000	29.0
Motor and gear loss	5,000	11.0	16,900	10.2
Total	45,315	100.0	165,460	100.0

The first two items, which are more than 50 per cent of the input, represent useful utilization of power in the sense of attaining the objective of transportation service, i.e., speed. The remaining three elements represent losses whose reduction is, of course, desirable.

Comparing the two runs the kinetic energy, increasing as the square of the speed, is more than three times as great for the fast one. The accelerating current is correspondingly greater and the time running on resistance is almost three times as long. The rheostatic losses are eight times as great. This suggests the desirability of an improved control to reduce rheostatic losses, although this is important only in frequent-stop service, as illustrated by this rather extreme example. In general, energy consumption at double the speed is more than four times as great, all other conditions as to stops, rate of acceleration, etc., remaining the same.

Even to suggest such a thing as quadrupling the energy consumption would seem to most engineers almost preposterous, even though it resulted in doubling the speed. It would seem that so great a difference could hardly be justified in balancing the increased cost of energy against the reduced cost of transportation, yet this is not impossible. Here are actual cost comparisons:

	Cents
Present cost of energy per car-mile	3.5
Proposed cost of energy per car-mile (four times)	14.0
Increase	10.5
Cost of trainmen's wages per car-mile	16.0
Fixed charges on cars, shops and stations per car-mile	5.0
Present total car cost per car-mile	21.0
Proposed car cost per car-mile ($\frac{1}{2}$)	10.5
Decrease	10.

Here the increased cost of energy just balances the decreased transportation cost. Moreover, this takes no account of the certain increase in revenue, which any recognizable increase in speed has on the car riding habit. This example is given merely to show how far a company may go in increasing its power to secure speed.

But quadrupling the power on electric cars has other justifications. Some 1930 automobile models advertise a rating of 125 hp. for five-passenger vehicles, or 25 hp. per passenger. Present-day street cars may go as high as 200 hp. for 50 seated passengers, or at the rate of 4 hp. per passenger. On this basis we might increase motor capacities six times instead of four.

Obviously, a company is not likely to quadruple its power cost for increased car speeds until it has exhausted other means. First, waste time in schedules should be searched for and cut out, along with a study for stop reduction and more rapid acceleration, all of which increase schedule speed with little or no increase in power. Next, car weight should be reduced. In many new cars it is being cut in two. The fallacy that heavy equipment is essential for comfort and safety at high speeds is being exposed. Low-floor cars, small wheels, and high-speed motors all contribute to this end.

Probably the reason for the reluctance to use more power is that its cost, like every other item of expense, has been subject to rigid scrutiny and every effort made to reduce it. Power-saving campaigns have been the order of the day on most properties. The error in this procedure is the tendency to reduce the use of power at any cost. The energy consumed, as we have seen in the above analysis, may be divided into two parts, one a useful part devoted to bringing the car up to speed and the other a wasted part devoted to overcoming the various losses. Failure to differentiate between the useful and wasteful elements in energy consumption has been the cause of much loss to the industry. In a word, the industry has falsely economized on power, and thus sacrificed the most vital essence of transportation, i.e., speed.

Nobody questions the desirability of reducing power waste; but we have seriously handicapped ourselves in meeting our principal competitor, by failing to use freely and effectively our most distinctive ally, electric power. On the Cleveland Railway, we have felt for a long time that a larger use of power is justified and the experimental work which we have already conducted indicates the economic desirability of a still greater utilization in the future.

Pittsburgh Traffic Signal Controlled by Street Car Movement

DELAYS to street car operation have been reduced as a result of the installation of traffic signal apparatus at Ellsworth and Negley Avenues, Pittsburgh, to prolong the green indication when a car is approaching the intersection. A somewhat similar installation at Louisville, Ky., was described in ELECTRIC RAILWAY JOURNAL, September, 1929, page 835.

The traffic signal at Ellsworth and Negley Avenues has a cycle known as the "non-overlapped four-way amber" which displays a single indication to each street at any instant. The green indication on Ellsworth Avenue and the red on Negley Avenue are adjusted to be displayed

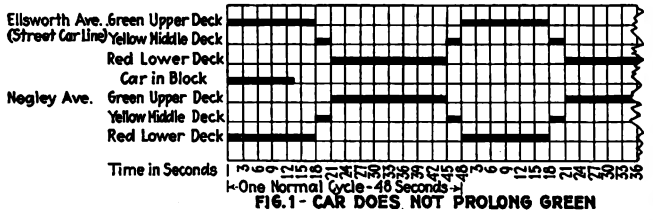

FIG. 1 - CAR DOES NOT PROLONG GREEN

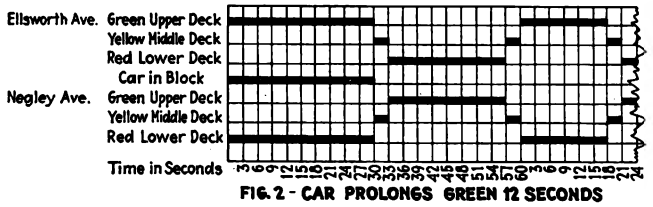

FIG. 2 - CAR PROLONGS GREEN 12 SECONDS

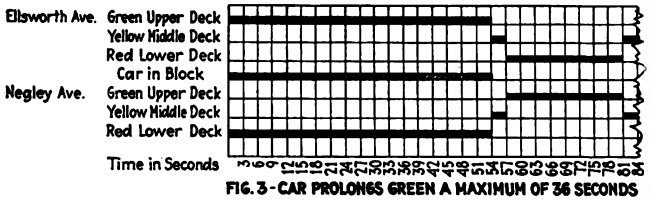

FIG. 3 - CAR PROLONGS GREEN A MAXIMUM OF 36 SECONDS

simultaneously for eighteen seconds, after which both indications change to amber, which is displayed to both streets for three seconds. At the end of this period the amber is extinguished and red is shown on Ellsworth and green on Negley for 24 seconds. Then amber is shown to both streets for three seconds. This cycle is repeated continuously by the motor-driven timer.

On each of the double tracks on Ellsworth Avenue there are two overhead trolley contactors, one set back 300 ft. before the car reaches Negley Avenue and the other placed at Negley Avenue. These contactors are actuated by the passing trolley wheel to form an electrical circuit. If a car passes the first or setting contactor to enter the control block with the signal showing green on Ellsworth, and passes the clearing contactor at Negley Avenue sooner than eighteen seconds from the beginning of the green display, the traffic signal indications are not disturbed by the movement of the car. If, however, the car passes the first contactor during the green display and does not pass the crossing until later than eighteen seconds, the green is prolonged until the clearing contactor is actuated. Then the amber and the red follow in the normal cycle.

It is evident, however, that the car should be able to prolong the green only up to some predetermined limit, and if it does not pass the crossing within that time, then the signal will go to amber and red automatically. In this installation the time-element relay has been set for a green maximum of 54 seconds, being a prolongation of 36 seconds.

Since the cycles will be of variable length as determined by car movements, it is evident that this signal is not adapted to a wave or progressive system involving a number of crossings, but is suitable only for an isolated crossing where there is a main street with heavy traffic and a cross street with much lighter traffic.

It is an advantage with this arrangement to make the green periods for the two streets more nearly equal than would be otherwise possible, and to prolong the green period for the heavily traveled street when the trolley cars with their heavy traffic behind them require it. It will be noted that in no event is the display of the red shortened to the approaching car. The distance the contactor is set back for the crossing is that through which the car moves during the display of the red.

The apparatus for this control was furnished by the Nachod & United States Signal Company. It involves a motor-driven timer, a relay box with contactor-operated relays and a time-element relay together wth four overhead trolley contactors located as described, all of which operate on the ordinary three-decked, four-way traffic signal.

St. Louis Tags Transfer Passengers

DEPARTING in a number of ways from ordinary practice, a new type of transfer has been perfected and put into use by the St. Louis Public Service Company. Adoption of the new transfer system is the result of months of exhaustive investigation and experimentation.

Two transfer forms are used on each route, one for each direction of travel. Both forms have "P.M." coupons on the free end and locality tear-offs at the padded end. On each form the tear-offs are arranged successively in the order in which the localities are traversed, with the starting point tear-off nearest the transfer body. Such arrangement prevents alteration of a transfer after issuance because a shortened transfer allows fewer privileges than one with more tear-off sections attached. The last tear-off on all transfers is marked "Emergency" for issuance when cars are off route, turned back, or in any irregular situation. The transfer is $5\frac{3}{4}$ in. long by 2 in. wide. Printing economies of over $1,500 a month are being realized because of the smallness and simplicity of the transfer.

When a passenger tenders a transfer for fare and desires to ride on another line, the trainman sets a punch mark in the square denoting the direction of his car, and returns the original transfer. This scheme does two things; it keeps the original transfer with the passenger until the end of the journey, thereby indicating to each trainman the origin and general direction or history of the ride, and it places the transfer in each intermediate trainman's hands for inspection.

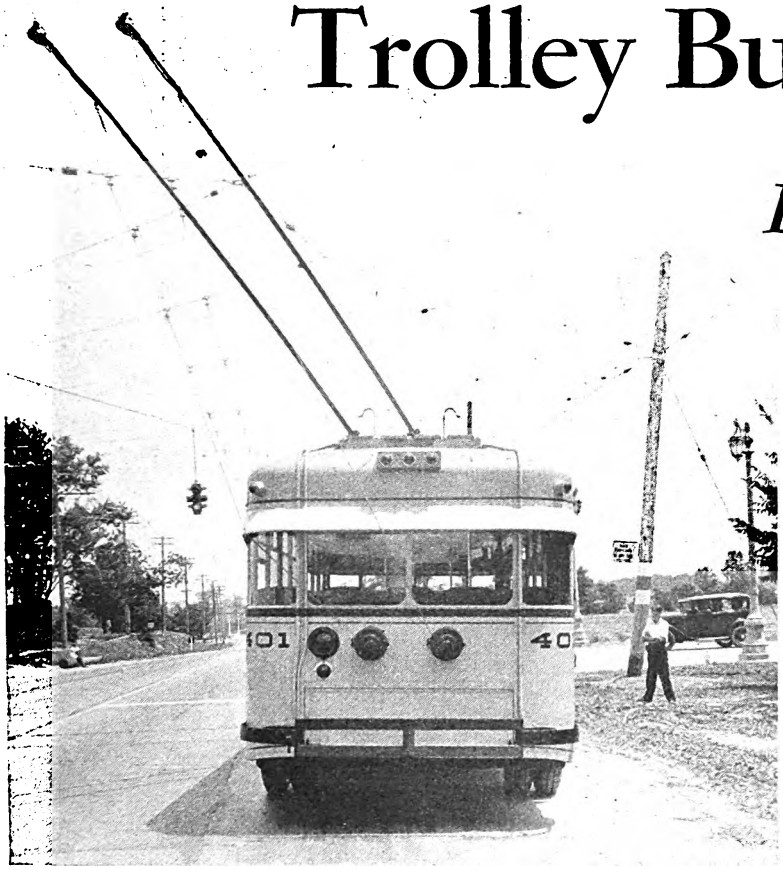
Trolley Bus Operation

Proves Advantageous at Detroit

High speed, curb loading, comfortable vehicles and quiet operation are factors in building up patronage



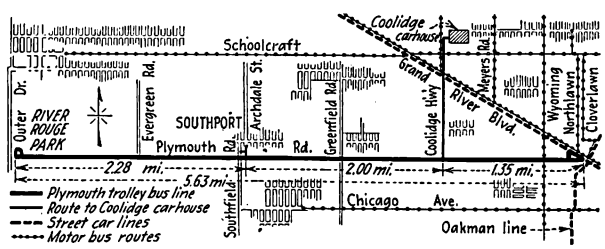
Trolley bus on the Plymouth Road line, Detroit. Note the overhead details, the trolley shoes and the wide smooth highway

DECREASED operating costs, increased traffic, improved public relations, and almost entire freedom from accidents are advantages of trolley bus operation on Plymouth Road, Detroit. Both the patrons and the management of the Department of Street Railways are pleased with this new type of service.

Compared with the buses which were formerly used on the line, reductions have been made from 4.80 to 2.02 cents per vehicle-mile for power, from 1.90 to 1.75 cents per vehicle-mile for tires, from 13.04 to 9.25 cents per vehicle-mile for maintenance of equipment, and in total operating cost from 29.21 to 21.95 cents per vehicle-mile.

It is expected that the trolley bus will be subject to comparatively few accidents. In the first four months, nine minor accidents occurred, but seven of these occurred during the first two months when the operators were still unaccustomed to the new type of vehicle.

The route, which is 5.63 miles in length, extends along Plymouth Road from Grand River Boulevard to River Rouge Park. It is located in the northwest section of the city and serves a rapidly growing residential district. Between Grand River and Southfield, a distance of 3.35 miles, the district is well built up. From Southfield to the end of the line, however, there are few houses. For this reason some of the vehicles are turned back at Southfield, to give more frequent service over this section of the line. Most of the traffic on the outer end is to and from River Rouge Park, which has a golf course, swimming pools, tennis courts, and other facilities for recreation. At the park end the buses turn around on a specially constructed loop. At the Grand River end they loop around a triangle which lies between Plymouth and Grand River. Connections are made at this point with the Grand River street car and parlor bus lines, the Oakman car line and the Schoolcraft bus line. At Wyoming Street the route crosses a bus line which gives rush-hour service. One large industrial plant, employing approximately 2,000 men, is located along the route.



The Plymouth Road trolley bus line in Detroit extends from Grand River Boulevard to River Rouge Park, a distance of 5.63 miles

In rush hours six-minute service is given on the line. During base hours fifteen-minute headways are maintained to Southfield and 30-minute headways to River Rouge Park.

A cash fare of 10 cents, with free transfers to street car lines, is charged. This is the same as for all bus lines.

Plymouth Road is particularly suitable for trolley bus operation, since it is a smoothly paved wide highway. Because of the condition of the street it is possible to operate at high speed. In June, the trolley buses were operated at a scheduled speed, including layovers, of 12.90 m.p.h. In July this was increased to 13.37, and in August to 14.33. Corresponding speeds for these three months in 1929 when a gasoline bus was being operated were 10.76, 10.26 and 10.46. Operating speed without layovers for the trolley bus in miles per hour is 15.33. This is 1.39 m.p.h. faster than the bus speed.

Digitized by Google

It is possible to detour around three lanes of traffic with the trolley buses. This maneuverability permits a high rate of speed

Six Twin Coaches were purchased for the original installation. They are of the 40-passenger type, with leather upholstered seats, treadle exit door and foot control. An interesting device on the vehicle is a switch on the trolley base for lighting a lamp near the operator when the vehicle swings too far from the center line of the overhead. Another noteworthy feature is the use of a reversible trolley shoe. This permits better collection of current at all speeds and practically eliminates overhead noise. Because the vehicle itself is inherently quiet, the use of trolley shoes is considered to be particularly advantageous.

At the present time the six vehicles are being stored and maintained at the Coolidge carhouse. The vehicles are stored in the open, but all inspection and repair work is carried on inside the shop. Plans are now being made for a new garage to care for the vehicles. When it has been built they will be maintained exclusively in this structure. The Coolidge carhouse is approximately 1.2 miles north of Plymouth Road and is reached by overhead allowing two-way operation.

To obtain the best information pertaining to the efficiency of the equipment, as well as schedules, and to note operating conditions in general, it was decided to discard the customary supervisor's and driver's reports because of their inherent insufficiency and to adopt some mechanical means of supervision, not requiring charts which entail a clerical force and clutter up files. After investigating the available instruments, a device known as the Telcam was adopted. A trial installation was made on a coach and later when the trolley buses were ordered, the specifications called for them as regular equipment. No charts are used, the cumulative totals being registered in roller counters, which are noted with each change of driver on a special report form.

The instrument gives the following readings at a glance:

Total Mileage—This counter is at the bottom of the dial and saved the cost of an odometer.

Total Running Time—At the top and extreme right of the instrument's face a counter registers the time in hours and tenths that the bus is actually moving, including all stops up to fifteen seconds' duration. This information will aid in reducing non-revenue time.

Total Overspeeding Time—This register shows how many minutes the bus is run above the speed limit, which for this line has been set for 25 m.p.h.

Number Times Overspeeded—This counter records the number of times the bus was run above the set speed limit. This is called the "abuse factor."

Maximum Speed—A secondary hand on the dial (painted red) is a maximum speed indicator, and is carried forward by the speed pointer, remaining at the maximum speed until reset with a key held at the garage.

A recapitulation is made of information obtained from the daily reports showing the performance records of each bus for the month. A report also is made of each operator's performance. A glance at these gives an accurate check of practically every factor pertaining to the efficiency of the operators and vehicles, as well as the schedules.

Overhead is provided for two-way operation along the full length of the route. Each pair of wires is located so that the vehicles running directly under them will clear a parked lane of cars safely. This permits easy access to the curb and a swinging out to clear a parked lane of cars and two moving lanes. The overhead, which is of the most modern type, was constructed in record time.

Riders Approve New Service

To learn the opinion of the public regarding the trolley bus the department distributed cards among the riders which stated: "We desire to know how we can better serve Detroit with transportation. The trolley bus is our idea of the latest and most superior service. Will you help by expressing your opinion?" Of 170 cards filled in, 167 were favorable to the trolley bus. In addition to many enthusiastic replies, certain of them requested extensions to the existing line, and the installation of new routes in other sections of the city. Among the many reasons given for their preference were: safety in boarding, absence of exhaust fumes, comfortable riding, quietness, convenience of curb loading, cleaner, faster, no gear noise, no dust, dependable, safer, more seating capacity, better ventilation, more flexible, roomy, ability to maintain schedules, restful, free from vibration, faster acceleration and stopping, no jerking, less interference with traffic and nice appearing.

Service was started on Plymouth Road on Saturday afternoon, June 14. The first of the six vehicles carried city officials, headed by Mayor Bowles of Detroit and Mayor Ford of Dearborn. Residents of the neighborhood were invited to ride on the other five buses and to take part in the ceremony. On the way to the park from the Grand River terminal a stop was made in front of the plant of the Kelvinator Corporation, where the employees to be served by the line greeted the officials. They were addressed by Mayor Bowles. At the end of the line several hundred persons gathered for the inaugural program.

Heating Passenger Trains on Electrified Steam Railroads

Practice of American and European roads summarized by N.E.L.A. committee. Both steam and electric heat are used extensively

METHODS of heating trains on electrified sections of railroads in Europe have been investigated by a sub-commitee of the committee on electrification of steam railroads of the National Electric Light Association. Some time ago, members of this committee spent about two months visiting the electrified railroads in England, Holland, Sweden, Germany, Switzerland, Italy and France. It was found that practice differs to some extent in the various countries and with the systems of electrification employed.

Briefly, the several means of heating which have been tried in those countries using single-phase alternating current on the contact lines are:

1. Fuel-fired steam boiler either in the locomotive, a baggage car, or a special heater car.
2. Electrode type of electric steam boiler carried in the locomotive or a baggage car.
3. Resistance type electric steam boiler in the locomotive or the baggage car.
4. Direct heat from transformer on locomotive.

Railroads using low-voltage direct current employ electric heat directly on the motor car trains, but usually heat with steam from coal-fired boilers on main line trains. Where these roads use electric heating, it is customary to have a train line of the same voltage as the contact line. The conclusion of the committee is that on a.c. roads, the present tendencies seem to favor a heating tender and direct heating from the main transformer of the locomotive.

Where electric heating is used on the single-phase roads, present practice indicates the adoption of 800 and 1,000 volts as the standard supply, this voltage being obtained by a special tap on the transformer in the locomotive. Many of the cars used on the main line

railroads are equipped for both electric and steam heating.

On European d.c. roads, heating of multiple unit cars is usually at the trolley or third-rail voltage; 600, 1,200 or 1,500 volts. Heating units taking 3,000 volts are in use on the Nord Milano road in Italy.

As to capacity in general, 40 kw. per passenger coach is allowed for heating, or a total of 400 kw. per locomotive. No reference is made by the committee to thermostatic control, and it is assumed that practically all of the equipment inspected was arranged for hand control either by the engineer, trainmen or passengers.

Following is a condensed statement of the practice reported for the several European countries visited:

England—Electric operation is confined to suburban service around a few of the large cities. Heating is done at the contact line voltage, either 600 or 1,200.

Holland—The state railways use 16,000-volt single-phase current. Both locomotives and coaches are heated from individual heating units receiving power from taps on the main locomotive transformer. Voltages for heating are nominally 600, 800 and 1,000. This permits interchange with the cars of the German State Railways, which use 800 and 1,000 volts. A heating bus line runs throughout the train carrying the positive wire and the heaters are grounded.

Germany—The suburban lines around Berlin, which are now being changed to electric traction, use multiple-unit cars supplied from a third rail at 850 volts d.c. The power is used directly for heating the motor cars. On the branch lines in Bavaria and Silesia, the cars are supplied from the 16,000-volt a.c. trolley through special taps on the transformers. On the lines with electric locomotives, in several instances, heating tenders with coal-fire boilers are used. A regular program is under way for installing electric heaters on passenger cars to eliminate the necessity for this auxiliary. On trains supplied with electric heat from the main transformer of the locomotive, a heating bus line with standard jumpers runs the length of the train. In each compartment control switches are installed which may be manipulated by passengers or trainmen. Heating voltages are nominally 800 and 1,000.

Sweden—Locomotive-hauled trains are used on the principal lines that have been electrified. The plan for heating is similar to that mentioned for Germany.

Switzerland—The system used is practically the same as that described for Germany and Sweden. In fact, much of the development work which was done before the adoption of the present practice in those countries was done in Switzerland. It is interesting to note that passenger coaches which are normally hauled by electric locomotives, and which cannot receive heat from them while standing alone in stations, are heated by means of special transformers mounted on portable trucks which can be moved around the station on the running rails. On the Loetschberg line, an experiment was made with steam boilers heated by electricity. When it was learned that the amount of energy required was three times as great as that for direct electric heating, the method was discontinued.

Italy—A majority of the electric trains in Italy are heated by coal-fired boilers carried on separate tenders. An oil-fired boiler is being tried out on one of the three-phase passenger locomotives. On account of the comparatively small requirements for car heating the problem does not apparently receive the attention which it is given in the more northerly countries. On the privately owned Nord Milano line, which has 3,000-volt d.c. multiple-unit cars, a bus line is carried across the car roof, and heating elements using 3,000 volts are arranged in two parallel groups so that the amount of heat can be controlled by the trainmen.

France—Multiple-unit trains in the vicinity of Paris operating from both 650 and 1,500 volts are electrically heated, using power at contact line voltage. On main-line trains hauled by electric locomotives it is customary to use heating tenders.

United States—For comparison with domestic practice, the accompanying table has been compiled from information supplied by the General Electric Company, giving briefly practice of the various railroads in the United States. On only one road where coaches are handled by electric locomotives are they heated electrically. This is on the Butte, Anaconda & Pacific Railway, which uses 2,400-volt hot-air heaters. The roads having multiple-unit motor cars use electric heat, the supply to the heaters being governed by thermostats on each car to maintain uniform temperatures. In the New York Terminal zone of the Pennsylvania Railroad, on the Michigan Central and the Canadian National (St. Clair Tunnel) electrification, no provision is made for heating cars within the electric zone, since the runs are comparatively short and the cars are heated by steam connections at the terminals. On motor cars on the alternating-current lines of the Pennsylvania, heating is from low-voltage taps on the transformer of each car, giving approximately 600 volts. The circuits are hand controlled at the discretion of the trainmen.

Richey Fare Index Revised

COMPILATION of average fares, which is made monthly by Prof. Albert S. Richey and regularly published in ELECTRIC RAILWAY JOURNAL, has just been revised on the basis of the population of the various cities as shown in the 1930 U. S. Census. These average fare figures are based on the cash and ticket fares in effect in all United States cities of more than 50,000 population (except New York City) and are weighted in accordance with the population of the various cities. As previously computed, the total number of cities included was 145; the 1930 census adds 46 cities in the 50,000 class and drops two, so that there are now 189 cities included in computing the average. A study of fares in connection with the revision showed that 102 cities out of the total of 189 (comprising 53 per cent of the total population considered) have average fares of less than 8 cents, and that such cities have shown an increase in population of about 43 per cent since 1920. On the other hand, the 87 cities which have average fares of 8 cents or more include a population of only 47 per cent of the total, and have increased in population only 21 per cent since 1920. The more rapid growth and the larger total population of cities with fares averaging less than 8 cents explains the reduction in the weighted average fare figure from 8.01 cents, as calculated on the 1920 population basis for October, 1930, to 7.79 cents, which is the revised average as calculated on the basis of 1930 population.

Revision of Richey Fare Index to 1930 Population

	1926	1927	1928	1929	1930
January	7.32	7.38	7.50	7.58	7.67
February	7.35	7.40	7.50	7.61	7.69
March	7.35	7.39	7.52	7.61	7.69
April	7.35	7.39	7.52	7.61	7.71
May	7.35	7.39	7.52	7.61	7.76
June	7.36	7.39	7.52	7.61	7.77
July	7.35	7.45	7.53	7.61	7.77
August	7.35	7.45	7.54	7.61	7.78
September	7.35	7.46	7.54	7.61	7.78
October	7.37	7.46	7.54	7.61	7.79
November	7.38	7.48	7.57	7.62	...
December	7.38	7.48	7.58	7.62	...
Average	7.35	7.43	7.53	7.61	...

The weighted average fare has further been recomputed for the past five years so as properly to join the averages as computed prior to 1926 with the revision on the basis of 1930 population. In such revision of the averages for 1926-1930, inclusive, it has been assumed that the change in population has occurred at a uniform rate during that period. The revised figures are shown in the accompanying table.

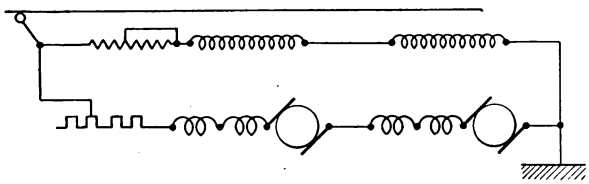
Regenerative Equipment

Planned for Paris Tramcars

Compound-wound motors with simplified control and use of automatic braking save 25 per cent of propulsion energy, besides increasing speed, reducing brake wear and maintenance. Recommendation for rebuilding all modern motors on the system was made as the result of extensive tests on twenty equipments

MODIFICATION of the electrical equipments of all the motor cars of the Société des Transports en Commun de la Région Parisienne, the government-controlled company that operates all transport facilities in Paris and vicinity, is contemplated by the management. It is proposed to change over the equipments on all of the cars having modern motors with commutating poles and capable of being converted into compound motors, the total motors involved being 2,350. A recommendation also has been made to the Department of the Seine, the governmental agency controlling the system, to retire 695 cars equipped with old-style motors and replace them with modern cars equipped with compound motors.

This information was made public at a special meeting of the Union Internationale de Tramways, de Chemins de Fer d'Intérêt Local et de Transports Publics Automobiles (International Tramway and Bus Association), held on Oct. 21-22 at Paris for the purpose of inspecting the new type of equipments. L. Bacqueyrisse, general manager of operation and technical service of the system, made the announcement at the close of a paper in which he explained details of the new method. He stated that the results of the tests, which have been conducted on twenty cars in regular service following extended investigation, have shown that the new equipments have numerous advantages as compared with ordinary equipments of series motors with series-parallel control.



Schematic diagram of control for two compound motors as developed in Paris

The advantages are summarized as follows:

1. Reduction in cost of energy, averaging 25 per cent, resulting from (a) lower rheostatic losses at starting; (b) economical running at low constant speeds; (c) regeneration of energy on down grades and when reducing speed, as at stops; (d) ease of operation and lessened influence of the personal element of the motorman.
2. Reduction of maintenance expense resulting from the easy progression in starting and stopping, with elimination of jerks, and the lessened wear on the braking system and the wheel treads.
3. Increase in the schedule speed.
4. Electric braking.
5. Low cost of the electrical equipment, due to its simplicity and its low weight and reduced complication.

The tests, which were made in Paris during the past two years, were intended to prove whether a material saving could be shown from the specific consumption of the latest lightweight cars (Type L) used in Paris. These cars, equipped with series motors with series-parallel control, are of the single-truck type with differential axles and worm drive. The specific consumption, due to various improvements, is 43.2 watt-hours per ton-kilometer (63 watt-hours per ton-mile).

Since regenerative equipments proposed in the past seemed to present too many complications, the Paris engineers decided that a material simplification would be necessary, and adopted compound motors with simplified control. It was felt that, to be successful, the equipments should be suitable for lines of varying profile, under conditions of traffic congestion and with short distances between stops, and that acceleration and braking rates should be sufficiently high to give acceptable schedule speeds, all with no greater complication for the operator than with ordinary equipments. According to Mr. Bacqueyrisse, these requirements have all been realized.

Existing Equipment Was Rebuilt

In order to have a satisfactory equipment for regeneration, it was found that the characteristics should permit a wide speed range. This requires satisfactory commutation with the field unsaturated, necessitating a high ratio of field ampere turns to armature ampere turns, a large air gap, pole pieces of appropriate form, and a large number of commutator bars. Two motors were selected for the tests, TH-523 and TH-563, both constructed by the French Thomson-Houston Company. On account of the low continuous rating of the TH-523 motor (25 hp.), both field and armature windings were modified. The TH-563, designed for rheostatic braking and rated at 36 hp., required a change in the field windings only. The commutating fields were not disturbed in either motor.

The number of series field turns was reduced materially and shunt field windings were added. The arma-

Range of schedule speed and energy consumption, compound and series motor equipments

tures of the TH-523 motors were rewound with square wire instead of round wire, thus increasing the rating 27 per cent. The weights of the motors have not been changed to any considerable extent. Stand tests have shown that the motors develop equal or greater power. For the input corresponding to the balancing car resistance, the motors have a maximum speed range of 5 to 1 with various values of shunt field current. At this portion of the curve the efficiency is in the neighborhood of 88 per cent, which is the maximum for the series motor, while at maximum load the efficiency is 84 per cent.

The schematic connection diagram shows that the armatures, the series fields, the commutating fields and a starting resistance are all connected in series across the line. The shunt fields are connected in series with a regulating rheostat in the circuit. Starting is accomplished with full shunt field on the motors by cutting out the two steps of series armature resistance. Beyond this point increases in speed are made by weakening the shunt field by inserting resistance.

Reduction of shunt field resistance causes the armature to generate an electromotive force greater than that of the line, so that the armature generates current which is returned to the system. This return of energy evidently is accompanied by a reduction of speed as the kinetic energy is converted into electrical energy. A similar effect is produced when the car goes down a grade steep enough to more than overcome the car resistance.

The speed variation of 5 to 1, which corresponds, with the gear ratio adopted, to a range in car speed between 6 and 30 km.p.h. (3.7 and 18.6 m.p.h.), which keeps within the speed permitted by the authorities, permits elimination of the series-parallel transition and simplification of the control.

While the armatures might be connected in series or in parallel, it has been found advantageous to connect them in series to obtain equal division of load and reduce the voltage between commutator bars.

Regeneration of energy, effected by strengthening the shunt field, is readily carried down to about 8 km. p.h. (5 m.p.h.). At this point, only about 7 per cent of the energy in the car at 30 km.p.h. (18.6 m.p.h.) remains in the car. While it might be possible to regenerate down to very low speeds, the value of that procedure is questionable. It requires mechanisms that are heavy, complicated, and difficult to control, according to Mr. Bacqueyrisse.

Besides regeneration, a number of other important advantages are obtained. With the fields completely saturated, the minimum speed on full armature voltage is reduced, so that the series resistances and the rheostatic loss are much less than with series motors. For the same reason, low constant speeds can be obtained, which are useful for slow running on a congested street behind a line of traffic. The comfort of the passengers and wear and tear on the equipment are lessened by elimination of the large number of series resistance points and of the series-parallel transition. Also, with smoother starting and stopping, higher rates of acceleration and braking are feasible.

Elimination of coasting permits an increase in the average speed of the run along with lower energy consumption, as the energy is regenerated during the retardation period. This gain in speed is considered important under present-day conditions.

Braking, like starting, is obtained at high rates due to successive reductions in the shunt field resistance. Below 8 km.p.h. there are two steps of dynamic braking, which bring the car to standstill. On account of the shunt field it is not necessary to reverse the armatures, and the series fields are short-circuited to prevent any differential action. Air brakes are unnecessary, and there is a marked reduction in the cost of maintenance of brake shoes, wheels and brake rigging.

Control Equipment Simplified

The controller and wiring, shown diagrammatically, indicate the simplification of the connections. There is a main controller drum with ten running points, two rheostatic braking points and one off point; a reverser cylinder with five positions, two for forward and reverse movement, two for emergency braking only by short-circuiting the motors, and one off position; an interlock between the main drum and the reverser; a device for shunting the series fields, which permits variation of the ratio of series ampere turns to shunt ampere turns, on which depends the rate of regeneration and the stability of action. On the neutral position of the reverser, all circuits are dead; but on the off position of the main drum, a small current flows through the shunt field circuit so that surges from opening it at every stop are avoided. A voltage relay inserts a resistance in the shunt field circuit so as to limit the electromotive force generated to 675 volts in the event of the failure of power supply or a dewirement

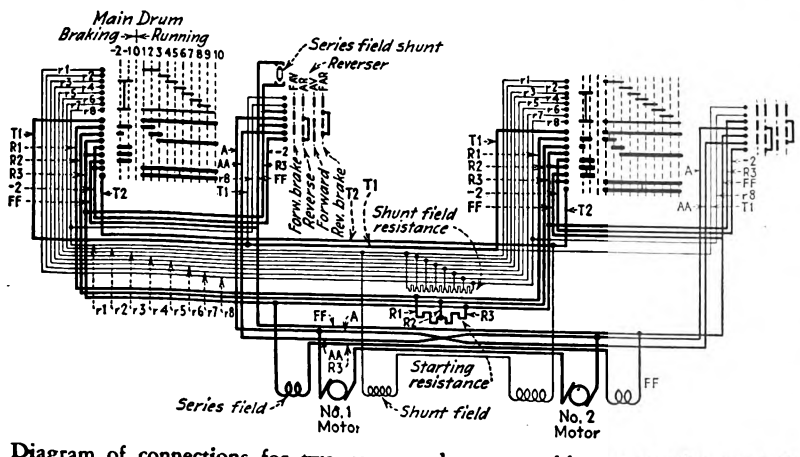

Diagram of connections for two compound motors with regenerative control

Comparative curves for a run of 250 meters. Results with compound motors at left and with series motors at right. Comparative figures are shown below

	Compound Motors	Series Motors
Time of run, seconds	44.9	46.4
Maximum speed, km.p.h.	30	30
Schedule speed, km.p.h. (10 seconds stop)	16.47	15.95
Energy absorbed from line, kw.	244	202.5
Energy regenerated	99.5	0
Energy taken, net	144.5	202.5
Energy used, watt-hours per ton-kilometer	35.4	49.7
Energy lost in resistance, watt-hours	28.6	50.2
Energy lost in resistance, per cent of input	11.5	24.8

of the trolley. There also are the usual cutout switches for use if one motor is disabled.

As may be seen, the wiring is greatly simplified. The total length of the power cables is reduced from 333 m. to 136 m. (1,100 ft. to 450 ft.), while the shunt excitation wiring is only 136 m. (450 ft.) of small wire.

Due to the reduction of weight of starting resistances, wiring, controllers, and series field shunting resistances, the weight of the car for regeneration is about 400 kg. (880 lb.) less than for an exactly similar car equipped with series motors.

Tests Show Material Savings

Tests were carried on with the first motor car changed over for more than 7,000 km. (4,300 miles) on the line between Porte de St. Cloud and Versailles. It was found that for the motor car alone the energy recuperated was 31 per cent of that taken from the line. On the up-grade trip the recovery was 18.5 per cent, while on the down-grade trip it was 59.5. The net saving compared with a car of exactly similar type under the same conditions of test, but fitted with series motors and series-parallel control, was 24 per cent. The specific consumptions of the two cars were 38.4 watt-hours per ton-kilometer (56 watt-hours per ton-mile) for the regenerative equipment and 50 watt-hours per ton-kilometer (73 watt-hours per ton-mile) with series motor equipment. The latter exceeds the average consumption for the system on account of the operating conditions imposed for the test.

Results obtained in normal passenger service have fully borne out the test predictions. It was found that a great advantage is the ability to run at any one of a number of constant speeds. This makes it possible to follow any traffic closely without successive applications of power and consequent jerking.

Energy consumption on the Louvre-Versailles line, which has a broken profile, showed a net saving of 27 per cent for the compound motor equipments hauling trailers, as compared with similar trains equipped with series motors. On Line 25, practically level throughout, but with heavy traffic congestion, Type G motor cars without trailers showed an energy saving of 23.8 per cent as compared with similar series motor equipments.

An important result found was that while there is considerable variation from the mean energy consumption with series motor equipments due to the personal element of the motorman, the individual runs with compound motor equipments ran much closer to the average.

The two speed-time curves reproduced indicate the results with the two types of equipment for a run of 250 meters, the limiting speed being 30 km.p.h. for each. The hatched areas represent the loss in starting resistance, which is 11.5 per cent for the compound motors and 24.8 per cent for the series motors. The net energy consumption per ton-kilometer was respectively 35.45 watt-hours for the compound motor equipment and 49.75 watt-hours per ton-kilometer for the series motor equipment. The schedule speeds are respectively 16.47 km.p.h. (10.21 m.p.h.) and 15.95 km.p.h. (9.89 m.p.h.), showing a gain of 3.3 per cent for the compound motor equipment.

Another study was made without the speed limitation of 30 km. The maximum speed attained in making the run of 250 km. was 35.5 km. (22.01 m.p.h.). The energy consumed was 26.68 watt-hours per ton-kilometer (43.1 watt-hours per ton-mile) for the compound motor equipment against 67.80 watt-hours per ton-kilometer (109 watt-hours per ton-mile) for the series motor equipment, the saving being 57.8 per cent. The ratio of energy regenerated to energy absorbed was 55.5 per cent.

It was pointed out by Mr. Bacqueyrisse that, contrary to the opinion frequently expressed, the compound motor behaves well with variations in line voltage. The compound motors are in use on a route which includes a section of underground conduit on which there are frequent breaks of the conductor rails with reversals of polarity.

It also was pointed out that the results were obtained with motors which were constructed from standard series motors with a minimum of modification. Motors designed specially for service undoubtedly would show better results. The series motors with which the new equipments were compared represented the latest designs of the manufacturers.

Studies made in Paris indicate that the cost of changing the equipments will be amortized in 6⅔ years on account of the economies. It also was stated that the use of compound motors should be of even greater advantage on rapid transit lines.

A.E.R.A. Executive Committee Meets in New York

CONSIDERATION of matters of national and local policy and the reports of committees constituted the principal business of the executive committee, A.E.R.A., at its meeting held in New York on Nov. 20.

C. D. Cass, general counsel, told of efforts to enlist action of member and non-member electric railways on behalf of an effort to secure from the government increased mail pay. There has been, he stated, no increase in mail pay to electric railways since 1925, although steam railroads less than 100 miles in length were granted an increase in 1928. The Parker bill for regulating interstate bus and truck operation, Mr. Cass reported, is still pending before a committee of the U. S. Senate. All recommendations on Referendum No. 57, being the report of a special committee of the United States Chamber of Commerce on water power development, were approved.

Contract for the use of the Atlantic City auditorium for the 1931 Convention has been signed, and arrangements for entertainment and meetings were well under way. Representatives of a score or more of the leading manufacturers, constituting the exhibit committee, have assured a large exhibit by agreeing to take as much or more space as their respective companies had used at the previous exhibit.

Leslie Vickers, economist, told of a recent meeting of the committee on fare structure, at which a resolution was passed soliciting the full support of the executive committee in obtaining from state and local regulatory bodies a wide degree of leeway in permitting local street railway companies to engage in fare experimentation.

Edward Dana, reporting for the committee on employee relations, stated that a foremen's training conference had been arranged for the Chicago area, and that preparations for holding similar training classes in other sections of the country were under way.

Cleaning Cars and Equipment by Sand Blast Saves Much Time and Money

SANDBLASTING of car equipment of the Pacific Electric Railway has proved more efficient and cheaper than the method of hand cleaning formerly used. Particularly in the cleaning of trucks its advantages are outstanding. Total elimination of all grease and dirt is possible, and all parts of the truck are cleaned down to the metal, affording better opportunity for the detection of fractures. Because all dirt and grease are confined to the sandblasting room, and not scattered around the main shops, general cleaning of equipment by sandblasting has improved the appearance and cleanliness of the repair shops on this property.

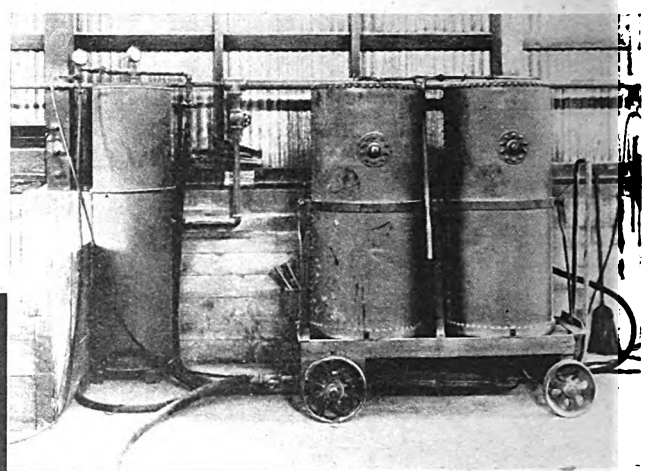
The bodies of both passenger and freight cars are cleaned by sandblasting, as well as trucks, armature coils, brush-holders, resistance grids, air hose couplings and many other parts. Hard, sharp silica sand is the cleaning medium used. This sand is cleaned and placed in two tanks which are mounted on a small hand truck. The tanks are used alternately; when one tank is emptied the nozzle line is shifted to the other tank. The tops of the tanks are concave to facilitate filling. A working pressure of 90 lb. is obtained from the shop air line. The rest of the equipment consists of a shop-made nozzle, and 1½-in. heavy hose connected to a 1-in. pipe, which is further reduced to ¼ in. by means of a reducing coupling before it is connected to the supply tank. Two men are required to perform the regular cleaning of equipment. One man operates the nozzle; the other screens the sand and maintains a supply for the nozzle line. Miscellaneous cleaning is done by helpers as the occasion requires.

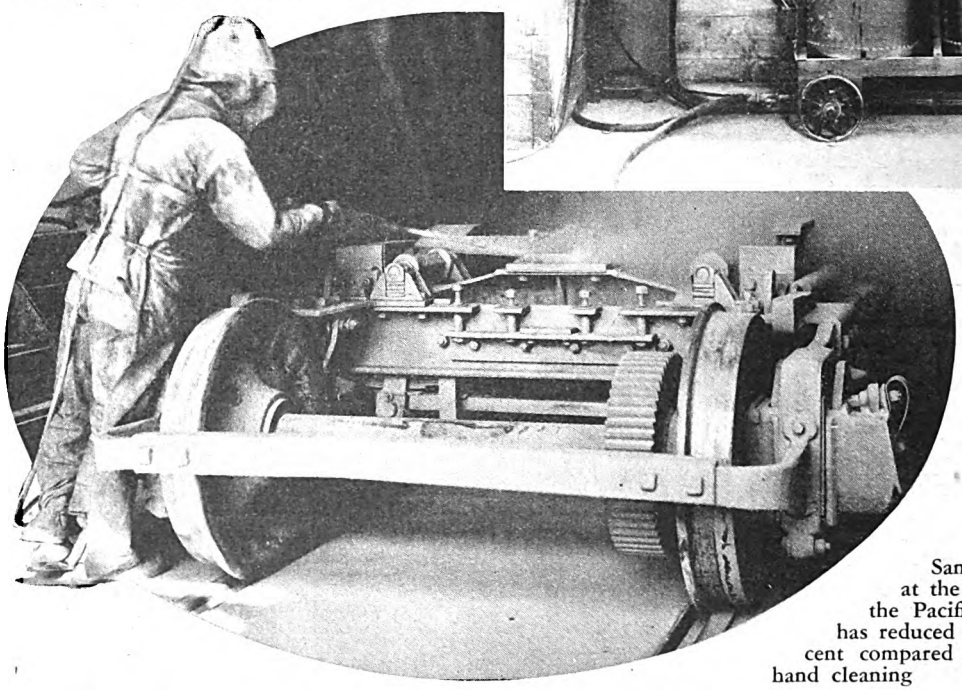
Except for trucks of passenger cars, no preliminary preparation is necessary in the cleaning of the equipment. It is taken into the sandblasting room and cleaned with little handling. Journals and the motor axle bearings of passenger car trucks are covered to protect them against the scouring action of the sandblast. The operator is protected with a Pulmosian helmet which covers the head and shoulders, and has a small air inlet in the top to provide ventilation.

The principal advantage of sandblasting is the saving in labor, as may be seen by comparing the labor time necessary for other cleaning methods. With the old method passenger cars were cleaned by removing the paint by means of a varnish remover, or by burning it off with a torch. This operation required the employment of four men for two days. Trucks were scraped of heavy mud or grease by hand requiring two men at least one day. Steel freight cars were cleaned by means of wire brushes, scrapers and putty knives, with a labor time of approximately 40 man-hours. Three man-hours were required to clean stripped armature cores with wire brushes and scrapers. Time required for typical cleaning operations with two men by means of sandblasting is as follows:

Steel passenger cars, including roofs and trucks	14 hours
Steel freight cars, complete	4 hours
Passenger car trucks, per car	4 hours
Steel gondolas, including trucks and frames	8 hours
Stripped armature cores	15 minutes
Brush-holders, resistance grids, air line hose couplings	2 to 5 minutes per article

Two supply tanks are used in the sandblasting operation. One is connected to the nozzle line, the other serves as a reserve





Sandblasting of trucks at the Torrance Shops of the Pacific Electric Railway has reduced labor about 50 per cent compared to the method of hand cleaning

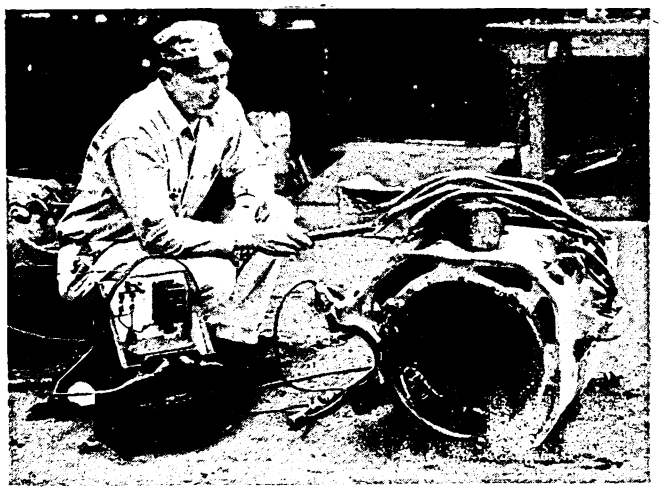
Insulation Tested with Portable Transformer*

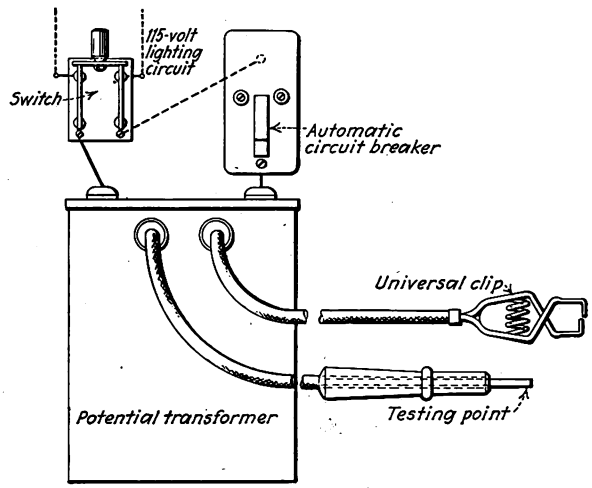
By A. Taurman

Superintendent of Equipment, Way and Structures
Birmingham Electric Company, Birmingham, Ala.

FIELD coils of motors, as well as motor leads, brushholders, car cables, starting rheostats and other electrical equipment, are tested for grounds with a portable potential transformer set connected to a lighting circuit in the shops of the Birmingham Electric Company. The field coils are tested when the motors are overhauled without the necessity of moving the motor to the electric testing shop, and the auxiliary equipments are tested on the car.



Much handling of equipment is eliminated by testing insulation with a portable transformer set in the shops of the Birmingham Electric Company



The potential transformer has a transforming ratio of 1:11, which makes available a sufficiently large voltage for insulation test from the ordinary lighting circuit

The set used consists of a 200-watt potential transformer of the switchboard type which was modified to suit requirements, a double-pole single-throw knife switch, a 15-volt, 25 amp. cap, and an automatic circuit breaker set to trip at 20 amp. The latter are mounted with the transformer in a wooden box to which is attached a convenient leather handle. The primary 115-volt winding of the transformer is equipped with a No. 14 lamp cord and attachment plug for connection to the lighting circuit. This connection is made from the transformer through the knife switch and circuit breaker. Highly insulated leads of suitable length are brought out from the secondary winding of the transformer to be attached to equipment for test. One lead is equipped with a 50-amp. universal clip, the other with a testing point. The transformer is wound for a ratio of 1:11, producing a voltage ranging from 1,250 to 1,265 volts on the secondary, with a 115-volt primary. If higher voltage is required, the secondary may be wound for a higher ratio, or may be split for different ratios.

Weighing only 35 lb., the complete set can be carried about easily and tests may be made wherever it is suitable. The test is easily and quickly made. The universal clip is attached to the motor frame, and contact is made between testing point and field terminal, holding the contact from 20 to 30 seconds. If the insulation of the field coil breaks down, the circuit breaker will trip and open the primary circuit.

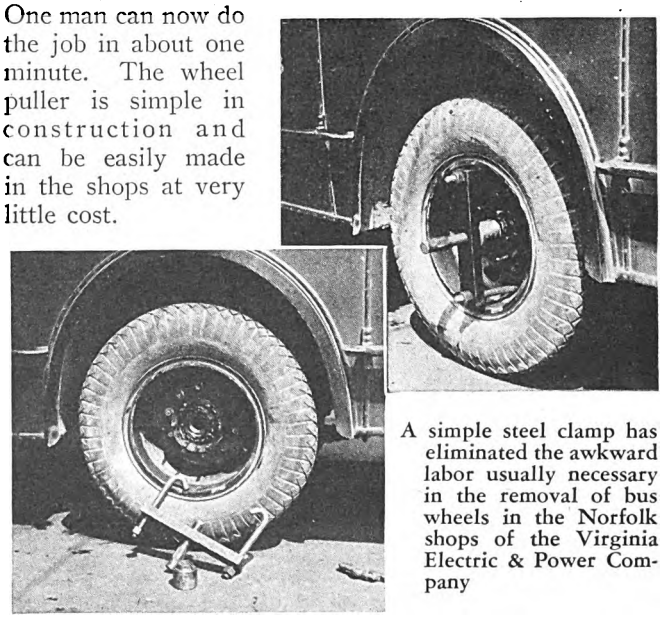
Bus Wheels Removed With a Simple Clamp*

By C. B. Hall

Chief Clerk Mechanical Department
Virginia Electric & Power Company, Norfolk, Va.

REMOVAL of wheels from the Model 65-A White bus is facilitated by the use of a wheel puller designed by the mechanical department of the Virginia Electric & Power Company, Norfolk, Va. This device is primarily an adjustable steel clamp made with 1-in. steel rod fitted into a body piece measuring 18x3x1½ in., which has a hexagon head screw 8½ in. long, threaded at the center. The diameter of the screw is 1½ in. A steel cylinder 3½ in. long is machined with a socket end for taking the screw, and a ¾-in. projecting plug end for insertion against the axle tubing. By turning the screw with a wrench against the cylinder and having the clamp ends tightened, the wheel is easily and quickly removed from the axle. Wheels were formerly removed with a jack and tools, requiring the labor of three men for from 30 to 45 minutes. One man can now do the job in about one minute. The wheel puller is simple in construction and can be easily made in the shops at very little cost.



A simple steel clamp has eliminated the awkward labor usually necessary in the removal of bus wheels in the Norfolk shops of the Virginia Electric & Power Company

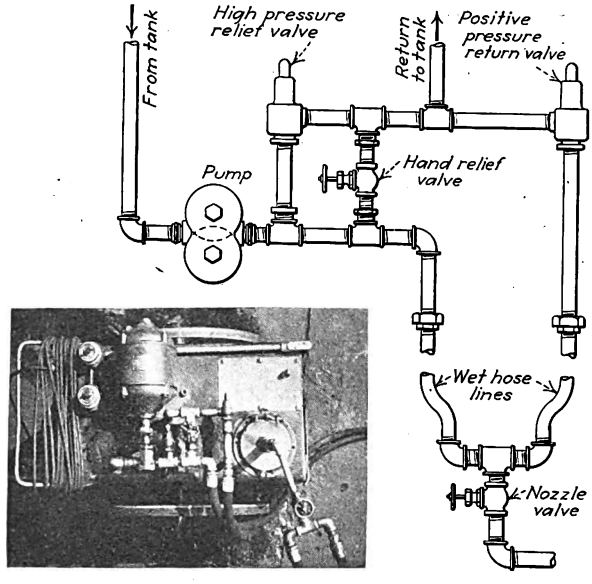
Pump and Heater Facilitate Transmission Filling*

By Leonard S. Rose
Assistant Superintendent Motor Coach Department
Cleveland Railway

FILLING of transmissions and differentials on buses operated by the Cleveland Railway has been facilitated by the use of a lubricant pump and heater developed by the motor coach department. Lubricant for the transmission and differential is carried in a standard rectangular oil buggy. On this a small direct-driven gear pump has been mounted. The output from the pump is delivered to a "wet hose" line, with a return hose to the tank which operates against a positive pressure return valve. Use of the wet hose return permits circulation of warm lubricant through the hose line so that the grease is fluid at the filling nozzle, even though some time elapses between periods of use. A



Positive delivery of lubricants to the bus transmission or differential is insured by use of this motor driven pump and heater combination

high-pressure relief valve protects the motor from overloads caused by the presence of cold grease in the hose line. The positive pressure valve insures a minimum delivery rate at the nozzle regardless of viscosity of the lubricant or its temperature. Flow from the nozzle is controlled by a small globe valve which may be regulated by the operator. In this way time can be given for the lubricant in the differential to level off and overfilling is prevented.

Since lubricants satisfactory for the purpose have high viscosity at average garage temperature, it has been found highly desirable to install an immersion heater in the bottom of the oil tank. This heater is connected up several hours before the tank is to be used, so that a satisfactory temperature will be obtained to permit easy flow of the lubricant and rapid leveling in the differential, as well as to give a lower load on the pump motor. A thermostatic heat control has not been installed, although it might be used if desired.

The initial investment and slight charge for power for the heater are more than offset by the quality and rapidity of the work done. A better job is done now with one man than it was previously possible with two.

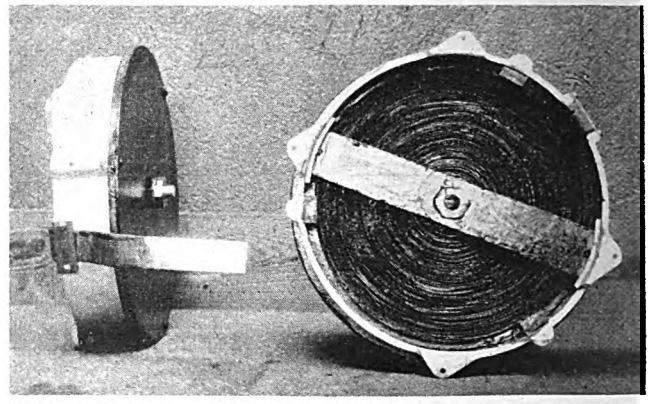
Radio Interference from Cars Eliminated by Choke Coil

By A. S. Warner
Transmission and Distribution Department
Metropolitan Edison Company, Reading, Pa.

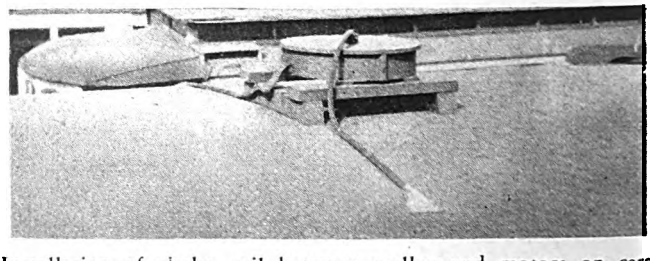
INTERFERENCE to radio reception caused by the commutation of motors on the cars of the Reading Transit Company, Reading, Pa., has been greatly reduced by the installation of a spiral wound choke coil between the trolley and the driving motors. The coil has 65



Choke coil is housed in an aluminum casting and held in position by a transite strip and three wedges

turns of No. 35 strap copper, and is housed in a circular aluminum casting having a ½-in. transite top from which the coil is hung by means of a center stud. Starting at the center stud, the coil is wound in a spiral with asbestos tape separating the turns. It is held in a fixed position in the aluminum housing by three maple wedges and by a 2½-in. transite strip. The coil is placed in the main bus line with the outside terminal connected to the trolley end and the terminal at the center stud to the motor end.

A filter arrangement, consisting of a choke coil and a condenser, would be more effective. The choke coil,



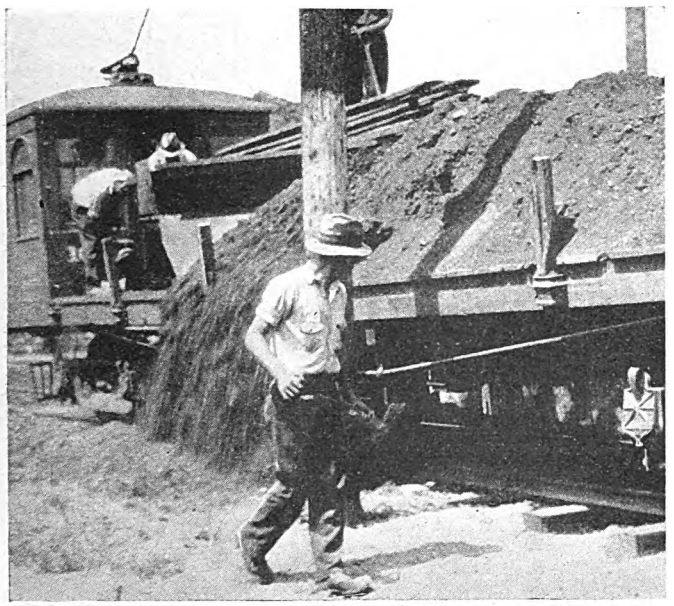
Installation of choke coil between trolley and motors on cars of Reading Transit Company has eliminated 95 per cent of radio interference

however, gave such satisfactory results that it was decided to use it alone. It was found to eliminate 95 per cent of the interference. The coil, moreover, is of rugged construction and requires very little maintenance. Approximately 115 cars have been equipped with this type of coil since 1928 without a single failure to date.

Digitized by Google

To supplement the effect of the choke coil, the field coil of the compressor motor was connected between the armature of the compressor and the trolley. This connection gives whatever benefit there may be in the choking action of the field coil against any interference originating at the compressor armature.

Work Car Equipped to Spread Material Along Track



Movement of plow along car floor spreads material along both sides of track

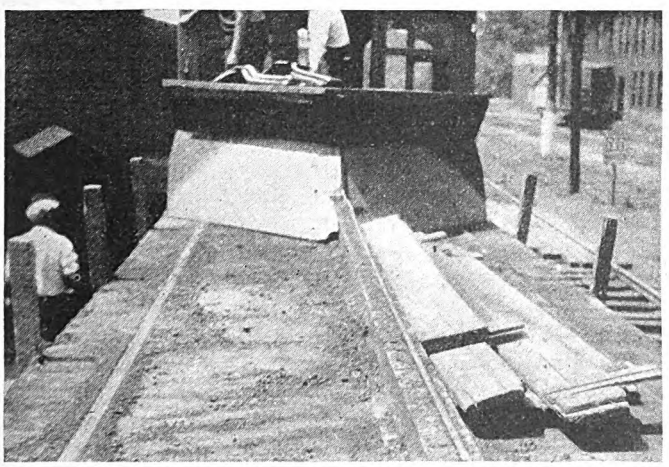
SPREADING of material along both sides of a track at the same time is accomplished with a work car built by the Stark Electric Railroad in its shops at Alliance, Ohio. An ordinary flat car is equipped with a plow, 4 ft. high, operating along a 12-in. I-beam which is placed along the center of the car floor. When the plow is moved forward, the material is spread along the sides at a rate determined by the speed of the plow and the speed of the car. The car is usually operated at 2 or 3 m.p.h. With planks placed along the sides, the car can be used for hauling and spreading ashes. With the planks removed, it can be used for hauling ties, poles and other similar material. When the plow is not in operation, it is placed near the control cab, leaving 42 ft. of clear car space for hauling material.

The auxiliary equipment for the operation of the plow consists of a 5-hp. motor, a steel drum, drum gears, and 100 ft. of steel cable. A wooden compartment, 30 in. high, 30 in. wide and 5 ft. long, incloses this auxiliary equipment. The wooden compartment is placed in the cab without interfering with the operation of the car. With the use of planks at the sides, about 20 cu.yd. of ashes can be loaded upon the car. The only manual labor necessary in unloading is for the removal of the side planks.

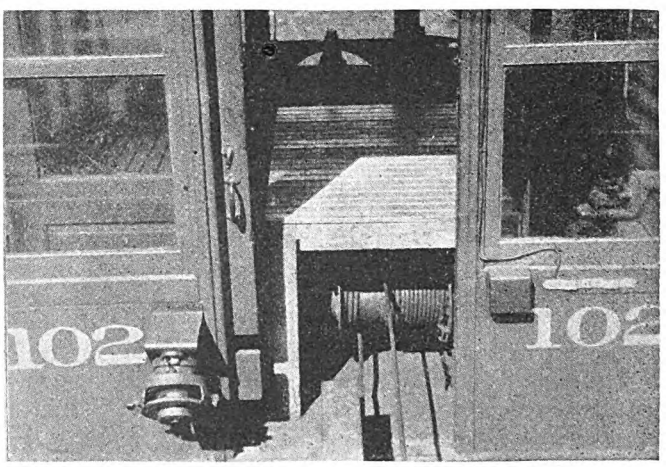
Remodeling Cars for One-Man Operation

CONVERSION of 65 front-entrance, center-exit, single-end cars for one-man operation is being carried out by the St. Louis Public Service Company. These cars, each with a seating capacity of 62, have been in service for about eight years as two-man cars. The brake valves formerly used on these cars are being replaced with a foot-operated self-lapping brake valve. The brake ratio based on the light weight of the car has been increased from about 100 per cent to 145 per cent. The operator is provided with a comfortable seat and is required to operate the car from a seated position at all times.

An emergency brake which is applied as a safety feature has been installed on each car and is intended to function only when the operator may not be alert and fails to hold it out of action. Electric heaters have replaced a stove heating system. The exit doors are operated by treadles and interlocked with the brakes in such manner that the brake is applied when the doors are opened and cannot be released by the operator until the doors are closed. The entrance doors are operated by air, but are not interlocked in any way with any other function of the car. Operation of cars on the rear end at slow speed is permitted with the back-up feature installed. Rattan seats have been faced around the edges with leather, and the seats themselves have been somewhat modified to make them more comfortable.



Steel cable pulls plow forward or backward along I-beam



Auxiliary equipment is conveniently housed in the cab of work car

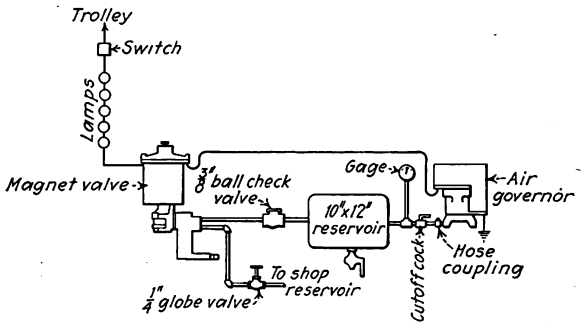
Testing Air Governors

By E. S. McGinnis
Foreman Electric Department
Dallas Railway & Terminal Company

AFTER overhauling governors it is often desirable to test them while they are off the cars. The Dallas Railway & Terminal Company makes this test by means of a simple arrangement, shown in the accompanying sketch, which consists of a $\frac{1}{4}$-in. globe valve, a $\frac{3}{8}$-in. ball check valve, a 110-volt magnet valve with suitable resistance, a 10x12-in. air reservoir, an air gage, a $\frac{1}{4}$-in. cut-off cock, and necessary $\frac{1}{4}$-in. piping and fittings. Air pressure is obtained from a reservoir in the shop.



Arrangement used by the Dallas Railway & Terminal Company for testing air governors after having been overhauled

The governor to be tested is connected to the reservoir by means of a suitable hose coupling and wired to the magnet valve through one terminal and grounded through the other. To begin the test, the main switch is closed. The governor, being in the minimum pressure position, closes the switch in the magnet valve circuit and causes that valve to open. Air is then allowed to flow through the ball check valve to the reservoir and governor. When the pressure reaches the maximum value, the electric contact in the governor is broken and the magnet valve closes. Back pressure from the reservoir causes the ball check to seat at this point. Pressure in the reservoir and governor is gradually reduced by allowing air to leak off to atmosphere through a $\frac{1}{64}$-in. hole drilled in the wall of the check valve. The air leakage passes from this hole to the exhaust port of the magnet valve. When the pressure in the governor again reaches the minimum value, the electric contact is closed and the operation is repeated.

Insulating Paste for Bolt Heads*

By E. V. Lackey
Armature Room Foreman
Ottawa Electric Railway

MANY of the automatic circuit breakers in use on cars of the Ottawa Electric Railway have been damaged by an arc, which occurred with a heavy overload, jumping to an unprotected bolt head. This short circuited the terminals through the frame and often burned out the overload coil. These bolt heads are difficult to cover by ordinary means, but a method of applying paste was developed which accomplished the desired result. This paste, consisting of powdered asbestos and shellac, was applied over the exposed metal parts. The paste was then heated by a flame until enough alcohol was evaporated to allow a crust to be formed. In a few hours the whole body of the paste was hard and formed an excellent fireproof protective covering. This method has been so successful in preventing the former trouble that it is now used on all rebuilt and repaired circuit breakers.

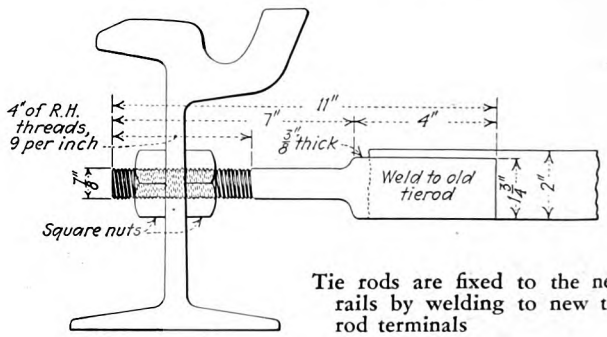
Submitted in Electric Railway Journal Prize Contest.

Economical Rerailing at Atlanta*

By D. S. Berman
Roadway Department Georgia Power Company
Atlanta, Ga.

DIGGING up less paving when laying new rails has been accomplished by the roadway department of the Georgia Power Company, Atlanta, Ga., by a new method recently adopted. It was desired to lay new rails in a street which was to be repaved by the municipality. The track foundation, of creosoted ties and grouted ballast, was in satisfactory condition and capable of lasting a number of years more. With the purpose of saving

Atlanta reduced paving cost by laying new rails on the old track foundation



Tie rods are fixed to the new rails by welding to new tie-rod terminals

labor and part of the paving, the new rails were laid by digging a 1-ft. wide trench on each side of the rail to the top of the ties, a section of paving about 2½ ft. wide remaining undisturbed along the center of the track. To pull up the old rails, it was necessary to cut the tie-rods. This was accomplished by burning them with a carbon arc about 7 in. from the rail. The relay rail was then laid in the trench and spiked to the ties. The old tierods were fixed to the new rail by welding one end of a new tierod terminal, 11 in. long, to the old tierod, and bolting the other end to the rail.

NEW PRODUCTS
for the Railways' Use

New Standardized, Light Weight Car Announced

INCORPORATED in the design of the new standard production model car, just announced by the recently organized General Car & Coach Corporation, are several features intended to lower first cost, operating and maintenance costs, increase speed, reduce noise and improve appearance. These objectives are to be attained principally by trucks equipped with worm drive and a new type of braking mechanism, and a carefully proportioned, lightweight body.

The car, which is equipped with two trucks and intended for city service, can be made either for single-end or double-end operation. In the former design seats will be provided for 52 passengers, and in the latter for 45 passengers. The estimated weight for the single-end car equipped with four motors, is 24,000 lb. For double-end it is 25,000 lb. Principal dimensions of the car are given in an accompanying table.

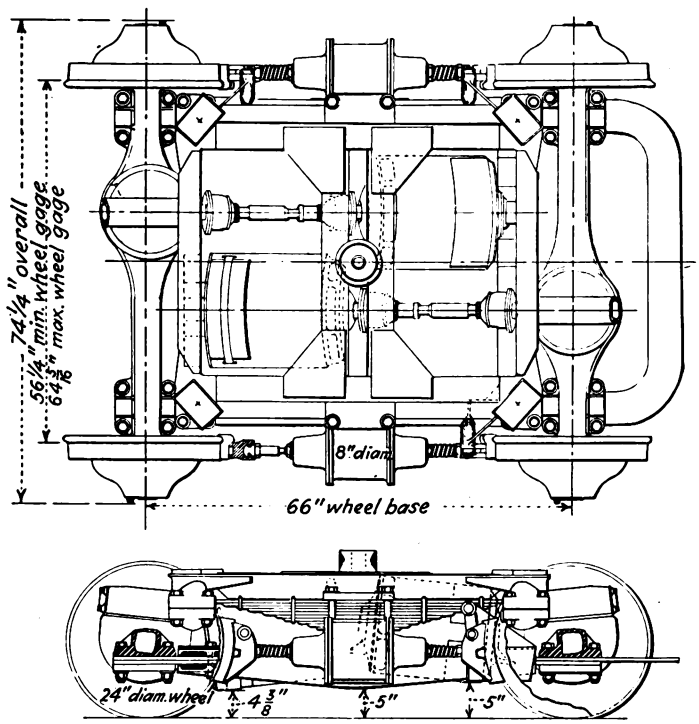
Although the weight of the car is only 24,000 lb. it has been so designed as to have adequate strength. The underframe and most of the body parts are to be of steel. Wheel guards are to be mounted on the truck to prevent wash on the underframe, an important factor in prolonging the life of the car. Particular attention has been paid to getting a low, racy appearance. A plain arch roof which extends on the sides to the windows, eliminating the letterboard, full streamline effect, wide windows, and a bumper on each end aid in giving this appearance. A double front door and a single rear door allow the use of the circulating load principle.

An unusual combination is service braking by foot and control by hand. Another feature is a hand brake for emergency use, similar to the type used in automobiles. Either Westinghouse or General Electric electrical equipment can be furnished.

Distinctive points in the design of the trucks are side mounted brake cylinders for actuating brake shoes, propeller unit disks for emergency braking, fully housed worm drive axles, rubber insulation of metal parts, four corner bearing plates, an axle aligner and wheel guards.

In the new braking system adopted, practically all brake rigging is eliminated. As may be seen in the drawing of the truck, a cylinder is mounted on each side to receive applications of air when it is desired to stop the car. Forcing a piston in each direction from the center, the conventional brake shoes are pressed against the wheels simultaneously. Aside from the elimination of conventional rigging, with its attendant noise, weight and necessity for frequent inspection, an advantage claimed for this system is that it can be inspected easily from the outside of the car and adjusted with the use of only two wrenches. The cylinders are connected to the air piping on the underframe by flexible tubing. As mentioned previously the air brakes are controlled by a pedal.

Supplementing the air brake is an emergency brake, which uses a disk, mounted on the propeller unit, and a handle similar to that used in automobiles for the operator to bring the shoes against this disk.



Details of the new truck, showing the brake cylinders and shoes, four bearing plates, stiffening bar and worm drive axle

Timken worm-drive axles, with each drive shaft mounted over the main axle, are to be used. The axles are to be inclosed with a single piece housing. No differential is used. Journal bearings are to be lubricated by Alemite fittings. The two motors for each truck are to be mounted on the cross members of the frame, giving full spring suspension for their weight.

Noise is to be reduced to a minimum by the elimination of all metallic connections, with the exception of the motor leads to the body. The springs are supported in rubber, as well as all other frame members. An innovation is the use of a graphite bronze bearing plate at each of the four corners of the frame. An important member of the truck frame is a U-shaped bar which passes underneath the two axles and extends around one of the ends. It is designed to keep the axles in perfect alignment.

Arrangements for the manufacture of this vehicle have been made with the St. Louis Car Company, St. Louis, Mo. Sales headquarters of the new company are at 100 State Street, Albany, N. Y.

Principal Dimensions

Length over buffers	40 ft. 1⅞ in.
Length over door posts	28 ft. 6 in.
Width at belt rail	8 ft. 3 in.
Height, rail to roof	9 ft. 8¾ in.
Height, floor to headlining	7 ft. 2 in.
Height, rail to first step	15 in.
Height, step to floor	13 in.
Post centers	47 in.
Seat spacing	30 in.
Wheelbase of truck	5 ft. 6 in.
Pivot centers of trucks	19 ft. 7 in.
Diameter of wheels	24 in.

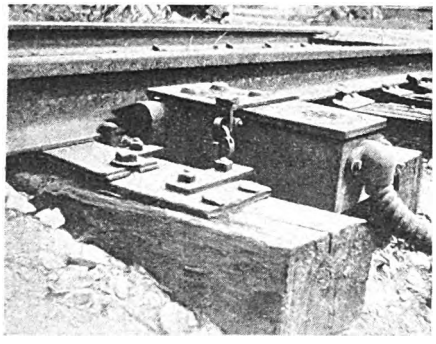
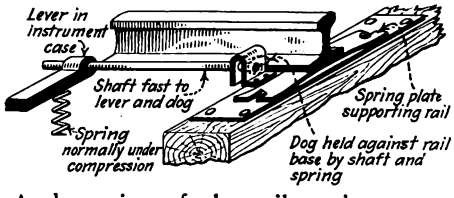
Highway Crossing Signals Controlled by Mechanical Rail Contactors

INCREASING interest is being shown by interurban electric railways in mechanical signal control. Several steam railroads have recently replaced track circuits by rail contactors in automatic signal territory to avoid cutting into the signal track circuits. With the track circuit type of control it is often necessary to rearrange two or three signal circuits or to install additional ones in order to secure proper operation of one



Mechanical rail contactor for controlling highway crossing signals, actuated by the downward movement of a spring supported rail

highway crossing signal. With a rail contactor known as the "Fusticlo," manufactured by the Louisville Frog, Switch & Signal Company, of Louisville, Ky., the control circuit is entirely independent of the track circuits. The Illinois Terminal System and the Northern Ohio Interurban Company are among those using this rail contactor.



A depression of the rail resting on a spring plate causes a turning of the dog held against the rail base, thus producing rotation of the shaft which actuates the contacts

A spring plate is placed between the rail base and tie, raising the rail about ⅜ in. Spikes are lifted about the same amount on the two ties each side of the tie bearing the spring plate, so that the hump in the rail spreads over five ties. A dog rests on the top of the rail base at point where the spring plate is located. This dog is securely fastened to one end of a shaft which has a lever fastened to its other end. A spring, normally under compression, is placed under the lever. The dog is thus forced against the rail base by the compression spring. This compression spring, however, is not of sufficient size to effect the deflection of the rail in the least. The other end of the lever engages the mechanism which operates a circuit breaker.

In operation, a train approaching the point where the spring plate is located depresses the rail and flattens the spring plate. When the rail is depressed the dog on the base of the rail follows the rail downward, due to the action of the compression spring, turning the shaft and moving the end of the lever which engages the mechanism upward.

There are two types of rail contactors in use at present, directional and non-directional. Directional instruments are commonly used as starters on single track. They are so arranged that contacts which are actuated by a train going in one direction will not be operated by a train moving in the opposite direction. In some special cases two sets of contacts are used in a directional instrument, in which case, one set operates for a train moving in one direction, while the other set will operate for a train moving in the reverse direction.

Non-directional instruments are used chiefly as stopping or cut-out instruments and also for starters on double track where no reverse movements occur. They have contacts which are operated by trains moving in either direction. The principle of operation is the same as the directional type, except that no selective device is employed.

Light-Weight Bus Body Introduced for Ford Chassis

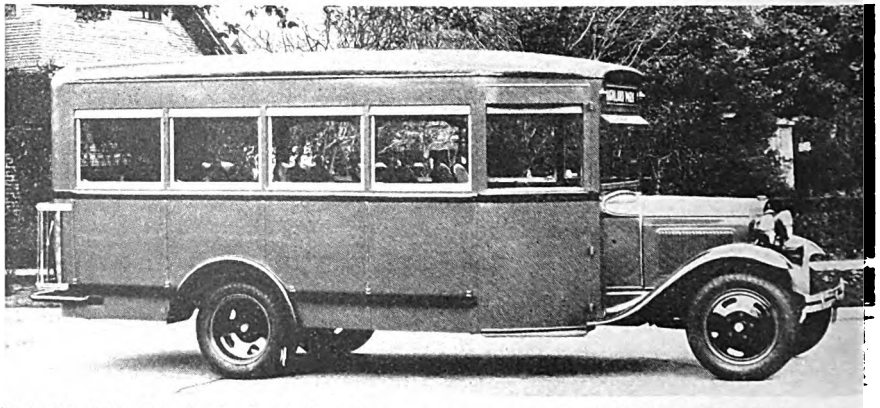
MEETING the demand for a moderately priced light-weight bus body to be mounted on the Ford Model AA 157-in. chassis, the Fitzjohn Manufacturing Company, Muskegon, Mich., offers a 21-passenger body in street car and parlor coach styles. The manufacturer states that it combines the feature of light weight with comfortable seating arrangement, ample headroom and aisle space.

Principal dimensions of the body are: belt length, 196 in.; belt width, 86 in.; headroom, 70 in.

The body weight has been held within the allowance necessary for mounting on the Ford chassis by the adoption of special body framing and lightweight metal bracing. It is claimed that the parlor coach body, completely equipped, weighs not more than 2,500 lb. Specially designed Ypsilanti Reed Furniture Company seats provide the necessary comfort and knee room.

Parlor coach body is equipped with inside baggage lofts for intercity operation

Attention is directed by the manufacturer to the fact that the cowl and dash assembly, being the type regularly furnished on Ford chassis, makes possible the mounting of these bodies at any point in the country.



This Fitzjohn bus body is designed for mounting on Ford Model AA 157-in. chassis

Digitized by Google

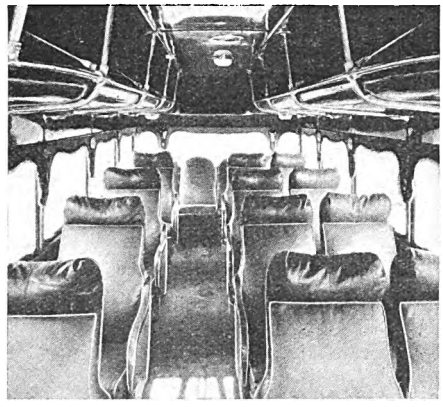
The framework is of seasoned ash and maple. New "Galvaneel" steel window sash by O. M. Edwards Company, and one-piece plate glass hinged windshield have been adopted. The entire rear end of the body, including the top roof corners, is of metal. Appearance is enhanced by a military front with a cadet visor and by the use of window eaves around the side windows. The parlor coach body is also fitted with ornamental grille window valances, and a Hunter roll sign together with a rear drum sign.

The interior is trimmed with textile ceiling and lacquered Masonite panels. Linoleum floor covering and Diamondette safety tread for entrance steps have been adopted. A spare tire is located on the left front side of the body. The rear bumper is of tubular steel and the side bumpers are of single bar cold-drawn steel. Accessories include a rear-view mirror and an automatic vacuum windshield wiper.

Additions in the Field of Low-Capacity Buses

TWO six-cylinder buses, a 16-21-passenger pay-enter city type and a sixteen-passenger interurban type, have been added to the line of the White Company. These buses are mounted on the Model 613 bus chassis and are designed for service where economical operation and flexibility in traffic are of major importance. Both have Bender bodies.

The interurban type has sixteen fully upholstered parlor car type seats of lightweight construction. The seats are liberally spaced and are equipped with concave head rests and hat clips on the back. Over each seat is a small dome light, eight in all, mounted under the baggage rack.



Comfortable and attractive interior of new White intercity bus

The seating arrangement provides for a row of single seats on the right side of the aisle facing forward and a row of two-passenger seats on the left side. A lightweight aluminum grille work, with a small target sign, incloses the two spare tires mounted in the rear. Space is provided above the rear roof of the body for handling excess baggage; interior racks may be used for hand baggage. The upper part of the pull-up windows is trimmed with a valance which extends down on each window post to the top of metal-framed mirrors. The heater is of the hot water type placed to the right of the dash. Four roof ventilators are arranged so as to provide an adequate supply of fresh air. General illumination is obtained from four large dome fixtures which are mounted in the roof.

General specifications are as follows:

Wheelbase, 180 in.
Net weight, approximate, 9,800 lb.
Length over-all, including bumpers, 24 ft. 8 in.
Dash to end of body, 18 ft. 7 in.
Center of rear axle to end of body, 72⅝ in.
Outside width, 78 in.
Headroom, at front, 72 in.
Headroom, over rear axle, 68 in.
Seat centers, 33 to 37 in.

Economy of operation and long life are the claims made by the manufacturer for the pay-enter body. The weight of this body has been held to a minimum. A generous seating space of 33 in. affords the comfortable room usually found in a de luxe type bus. Interior width is 84 in., using double seats measuring 34 in. with an aisle space of 16 in. An attempt has been made to eliminate the crowding effect of the small type bus by providing a headroom measuring 76 in. at the front door. This is made possible without undue over-all ıeight by a double drop-frame feature.

The 4-A engine used in the Model 613 is a six-cylinder "L" head type, 33¾-in. bore and 4½-in. stroke, with clutch and transmission mounted as a unit. It has a rigid crankshaft, mounted in seven main bearings, and a detachable head with machined combustion chambers. This engine delivers a torque of 175 ft. lb. at 1,000 r.p.m. Full pressure lubrication is supplied to all main connecting rods, camshaft, piston pin, accessory drive and chain idler bearings. The clutch is the White single-plate type operating in oil. All transmission gears are of chrome nickel, steel-carbonized and heat-treated. The rear axle is a one-piece steel casting with a single reduction of the semi-floating type. Brakes are the four-wheel internal-expanding type with molded lining, operated hydraulically with vacuum booster. Standard equipment includes 7.50-20 balloon tires, single front and dual rear.

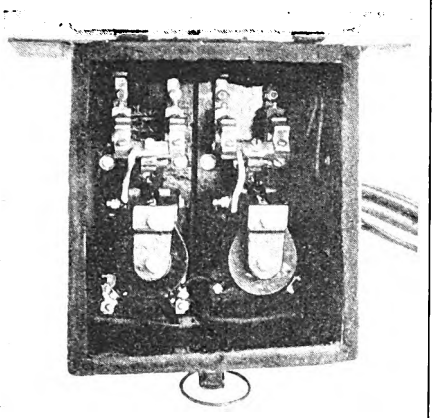
New pay-enter bus for city service developed by the White Company

Compact Field Shunting Switch

COMBINING the functions of two ordinary switches for shunting the fields of a pair of series railway motors, a lightweight switch, Type UM-22, with a novel arrangement of contacts, has been brought out by the Westinghouse Electric & Manufacturing Company.

As most railway motors are connected in parallel pairs, two switches for a pair of motors would always be connected together on one side. It is unnecessary, therefore, to bring out four leads, making possible a double-pole switch in which the moving contacts are not insulated from each other, and which has two incoming leads and a single outgoing lead. Since an important factor limiting the width of a conventional double-pole switch is the spacing between moving contacts for insulation, a switch can thus be made extremely narrow with

Digitized by Google



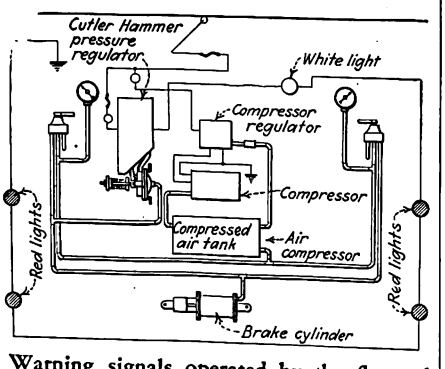
This contactor box contains two switches for four-motor equipments. Narrow spacing of moving contacts makes possible a reduction in weight

the two moving contacts mechanically and electrically interconnected. Equalization of contact pressure between pairs of contacts is obtained by the use of resilient stationary contacts and the usual spring in the moving mechanism.

One switch suffices for two-motor equipments and two switches for four-motor equipments up to 60-hp. rating. The switches and current limit relay, which controls them, are each inclosed in a sheet metal box for under-car mounting. For four-motor equipments, the Type UM-22-A field shunting contactor box, weighing about 45 lb., the Type TS-27 current limit relay box, weighing about 30 lb., and the Type M field shunting resistor, weighing 18 lb., are recommended by the manufacturer. Field shunting equipment for two-motor equipments weighs 25 per cent less.

Signal Lights for Car Stop Warning

AUTOMATIC operation of a safety signal system to warn pedestrians and motorists that a car is about to stop has been developed by Ashley Hale, West Groton, Mass. The danger signals are displayed at the front and rear end of the car whenever any appreciable amount of air is admitted into the brake cylinder.



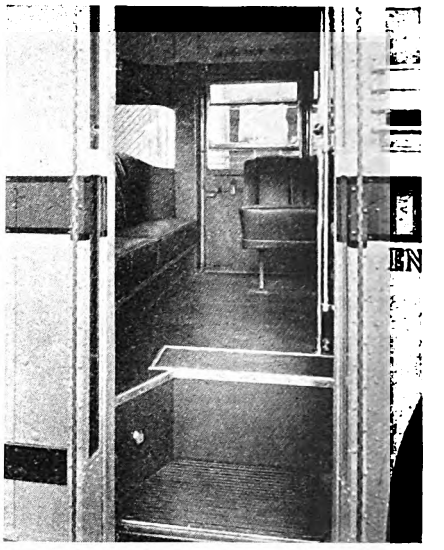
Warning signals operated by the flow of compressed air through the brake control

Operation is controlled by means of a Cutler-Hammer pressure regulator, Type C, which is incorporated into the braking system, as shown in the illustration. It is connected to the cylinder pipe so that, when air is admitted under pressure in any quantity to the brake cylinder, it will also be admitted to the pressure regulator. The lights are placed in series and are in circuit with the regulator which is fed directly from the trolley through a fuse and a switch. A clear lamp is placed inside the car and two pairs of red stop-indicating lamps are located on the dashers.

Rugged Thermostat Designed For Close Heat Control

RELIABILITY, rugged construction, neat appearance with no exposed screws, adjustments or openings in the cover to invite tampering by meddlers, are the advantages claimed for the heat-control instrument known as the No. 690 Arcostat, which has been designed by the American Radiator Company primarily for use on electrically heated street cars and buses. The instrument is finished in black enamel with Bakelite base, and has a snap-action contact by means of a permanent magnet. It is said to be unaffected by vibration, rolling or stopping of the car.

The differential of the instrument itself is $\frac{1}{5}$ of 1 deg. The actual differential obtainable on air temperature will depend upon the rapidity of air movement over the instrument, and the rapidity of temperature change. The more rapid the air movement and the slower the temperature change, the closer will be the control. However, the actual operating differential under any specific set of conditions can be determined only by a test. All adjustments are made at the back after removing the cover by means of a special screwdriver. The instrument is fixed to the wall by screws with heads, requiring a special wrench or key. There is no opening in the cover. Due to the use of a liquid-charged bellows element, this instrument will continue indefinitely to operate at the degree set.



Mats can be placed in step-wells and above step, being held securely in place with special molding strips

Tread Flooring for Safety and Cleanliness

UNDER the trade name of "Safety Treads," a novel type of flooring with grooved construction is marketed by the Melflex Products Company, of Akron, Ohio. It is claimed that this type of flooring prevents slipping by gripping the soles of shoes and that the grooves collect the moisture, sand and dirt to eliminate the excessively fast wear that would result if the gritty dirt were collected and ground into the treads.

The flooring is made from strong cotton cords embedded in a rubber compound, vulcanized and cut into strips. Each strip is then dipped in a special rubber cement and molded onto a tough rubber base. The strips in the tread are separated by grooves approximately $\frac{3}{8}$ in. wide.

This material is now in use on the cars of the Youngstown Municipal Railway and the trolley buses of the Department of Street Railways, Detroit.

Safety treads installed in the aisle of a Birney safety car

NEWS *of the Industry*

LATE NEWS

Dayton, Ohio.—The Cincinnati & Lake Erie Railroad, which connects Cincinnati, Dayton, Springfield, Columbus and Toledo, made a material cut in rates over the Thanksgiving holidays. The round-trip fare between any two of these places was the cost of a one-way ticket plus 10 cents.

✦

Boston, Mass.—The ninth annual educational program for the employees of the Boston Elevated Railway, just begun, will continue through March of next year. It will consist of sixteen courses and a series of forum meetings with prominent speakers. Last year more than 400 received certificates for successful completion of courses.

✦

Fort Wayne, Ind.—Robert M. Feustel, executive vice-president of the Midland United Company and chief operating head of the Insull utility group in Indiana, has been appointed chairman of the public utility division of Governor Leslie's state unemployment commission. At the preliminary conference of the commission called by the governor Mr. Feustel stated that efforts would be made to start the construction program by Jan. 1 instead of in the spring as originally planned.

✦

Chicago, Ill.—Officials of the Chicago Rapid Transit Company and associated transportation companies have received many commendations as the result of the service of a first aid and medical department at two recent large gatherings near Chicago. One gathering was at the National Air Races and the other at the state convention of the American Legion in Aurora, Ill. In each instance the Rapid Transit first-aid unit was the official medical organization of the event.

✦

Birmingham, Ala.—Control of the Alabama Bus Company and the Capital Coaches, Inc., has been purchased by the Consolidated Coach Company, Lexington, Ky. Mileage covered by the Consolidated will be 5,000 miles, operating 350 modern motor coaches. Birmingham will be on a through line from Mobile to Cincinnati and Washington. The new officers of the Consolidated company are: L. B. Herrington, president; J. P. Pope and Guy A. Huguelet, vice-president; A. A. Tuttie, secretary-treasurer. Messrs. Herrington and Pope are officers of the Kentucky Traction & Terminal Company.

✦

Rochester, N. Y.—The Public Service Commission has authorized the receivers of the New York State Railways to substitute buses for trolleys on its Laurelton-Browncroft route, here, and the town of Irondequoit. The fare to be charged is the regular 10-cent city fare to the city line and 5 cents from the city line to the terminus in Irondequoit, making the through fare 15 cents. City fares entitle riders to transfer privileges.

Rapid Transit Proposal Made at Montreal

Immediate Building of Eight-Mile Subway to Cost $65,000,000 Made on Behalf of Tramway in Plan Outlined by R. N. Watt

EMPHASIZING that steps should be taken immediately to meet the growing problem of traffic congestion and laying stress upon the fact that rapid transit is now recognized as a first fundamental in the growth of a city, R. N. Watt, assistant to the president of the Montreal Tramways, addressing members of the Rotary Club of Montreal on Nov. 18 brought to the fore the city's great need of subways as a solution to traffic and transportation problems. He submitted the following definite proposal:

1. The building of a subway of 8 miles, to be completed by 1936, with the following component parts:

(a) A north-south subway, running from Craig Street terminal to Laurier Avenue, with approaches from the latter station providing transfer under cover from the subway station to the car line—a distance of 2.35 miles. This would be located somewhere between Bleury and St. Lawrence Streets.

(b) The erection of an east-west subway, running from Atwater Avenue to Parthenais Street—a distance of 4.13 miles, located between Sherbrooke and Dorchester Street.

(c) A connection from the Craig Street terminal to the east-west line near Stanley Street, with a station at Dominion Square so designed as to give direct access to the C.N.R. and C.P.R. station—a distance of 1.40 miles.

2. The expenditure of approximately $65,000,000.

3. Certain minor modifications of the present contract between the company and the city of Montreal, which would permit the company to build and operate subways and, at the same time, protect the present investments of the company so that its financial position will not be adversely affected.

4. The guarantee of the bonds issued both as to principal and interest by the city.

5. A universal fare with universal transfer of seven tickets for 50 cents within the uniform territory.

6. Immediate action by the city authorities by which the above suggestions can be legally carried out and approved, and application to the Quebec Legislature to give authorization.

Mayor Houde, thanked the speaker. In his opinion the speech was the "best address I have ever heard on civic matters,

(*Continued on Page 774*)

The Business Outlook

BUSINESS shows more definite signs of having hit that hard-pan resistance level which in the past it has always encountered at about 20 per cent below normal. At this point apparently the fundamental human wants begin to reassert themselves. Basic industrial activity is still declining, but general trade has begun to expand at more than the seasonal rate. Money turnover is rising, commercial loans are expanding, currency in circulation is increasing with seasonal retail trade demand. As the automobile industry prepares to play its card courageously on next year's market, employment is being given some stimulus. Key commodity prices are firmer as resistance to further deflation grows. Bears in Wall Street and elsewhere apparently are beginning to look for winter quarters.

—*The Business Week.*

Economic Advantage Lies With Use of Electricity

Placing progress in transportation at the base of all industrial progress, Charles Gordon, managing director American Electric Railway Association, in an address before the southern district meeting A.I.E.E. at Louisville, Ky., on Nov. 19 showed how the dominating importance of the electric railway industry had stimulated the development of electric power, and pointed out the further opportunities of the electrical engineer in city planning.

Mr. Gordon traced the development of steam as power for railroad use and the early application of electric power to the problems of urban transportation. He showed how automotive power, coming into general use in the automobile, has made inroads into all phases of transportation, and how it has created a tendency in the minds of automotive enthusiasts to relegate electric urban transportation to the scrap heap. He said:

It seems particularly timely, that electrical engineers examine a little more closely than is usually done, the field of transportation in urban areas where the great electrical industry had its origin barely more than fifty years ago and where, in turn, it is already freely predicted that it is to be replaced by automotive power. In this examination we shall need to concern ourselves as much with economics as with engineering, for it is on the scale of economics that the achievement of engineers are finally weighed and finally judged.

With factual observations, Mr. Gordon spoke on the economics of the utilization of street space, showing how all forms of electric transportation were far more efficient than any means of service yet developed with automotive power. Mr. Gordon concluded:

It seems hardly conceivable that the enormous economic advantage of collective transportation by electric power will not be applied on a much larger scale in the future than at present, for the solution of the growing problem of traffic congestion in cities. It is true that a much higher standard of convenience and comfort for collective transit facilities is necessary. But compare it to the cost to the community of rebuilding our cities for automobile travel—the economic advantage is all with the electric power in the high traveled density of urban areas.

Digitized by Google

LATE NEWS

(*Continued from Page 771*)

New York, N. Y.—The city has been asked to make official study and report of suspended monorail system of transportation as a means of extending rapid transit relief to outlying districts in a resolution adopted by the Queens Planning Commission. The action follows an investigation of suspended monorail construction and costs, operation and safety features by traffic and transit committee of planning group.

✦

Toledo, Ohio—The Summit-Broadway line of the Community Traction Company, has been shortened by nearly three-quarters of a mile and the old Casino, once a popular amusement center of the railway on Maumee Bay, has passed out of existence as a transfer point, due to establishment of a new wye at LaSalle and Summit Streets as a meeting place for company cars and the Point Place bus line. A passenger station is being built by the company at that point.

✦

Newark, N. J.—According to Barron's, the loss sustained by the transportation division of the Public Service Corporation thus far this year practically offsets gains made by electric and gas departments, so that the earnings of the combined system are running at a rate approximately the same as in 1929.

✦

Kansas City, Mo.—The city has filed protest against an order of the Missouri Public Service Commission which authorized the Kansas City Public Service Company to increase weekly permits to 40 cents. The protest stated that the city had no opportunity to oppose granting of the new rate, which is an increase of 5 cents over previous fare basis. The cash fare is 10 cents. Holders display their permits and pay 5 cents additional for a ride.

✦

Milwaukee, Wis. — During the next several years large additional generating capacity for the territory served by the Milwaukee Electric Railway & Light Company will be made available with the building of the new $25,000,000 steam-electric generating plant at Port Washington. A federal permit has been granted for the necessary harbor improvements, and engineering work is being completed so that construction may proceed as quickly as possible. It is planned to have the Port Washington plant's first unit of 80,000 kw. capacity ready for operation during the latter part of 1932.

✦

New York, N. Y.—The Transit Commission called recently for public hearings to determine whether the Jamaica Central Railway, the New York Railways and the Second Avenue Railroad should continue one-man cars. The commission a year ago authorized their use of one-man cars if certain safety devices were installed. It is alleged that the companies failed to carry out this proviso. The commission has set Dec. 10 for consideration of the operation of one-man cars on the Graham Avenue line of the Brooklyn-Queens Transit Corporation.

Indianapolis, Ind.—Operating revenue of the former Union Traction Company for 1929 was $2,690,341, according to a report filed with the Madison Circuit Court by Receiver Brady. Gross income after deduction of operating expenses, taxes, etc., was $231,762. Total revenue from bus operations during the year amounted to $136,316 and expenses, $210,640. Last July the Union Traction Company was purchased by the Midland United Company and was succeeded on Aug. 1 by the Indiana Railroad. It is now being operated under centralized supervisory management in conjunction with the interurbans of the Interstate Public Service Company, Indiana Service Corporation and other subsidiaries of the Midland United Company.

✦

Salt Lake City, Utah—E. A. West, general manager Utah Light & Traction Company, speaking on the topic "Mass Transportation," told members of the engineering council that present conditions make railway extensions economically impossible unless railway companies are granted relief. He added that higher fares would not entirely solve the problem, and contended that the present paving tax should be eliminated. He said that the company, under present arrangement, is charged for pavement which causes an immediate decrease in its own business.

✦

Wellsville, Ohio—Discussion of terms of a new franchise for the Steubenville, East Liverpool & Beaver Valley Traction Company will take place here soon before R. H. Keay, chairman of the Council's franchise committee. The company's franchise expired on Sept. 19. Operations have been continued, pending arrangements for a new grant. In East Liverpool, a new grant is sought to replace the franchise which expired on Oct. 19. The company has asked continuance of the 7-cent city fare there, but wants the right to substitute buses for cars on a number of routes.

✦

Detroit, Mich.—The operating costs ot the Detroit Municipal Railway were reduced $40,000 when the street railways commission decided to eliminate this sum from the funds regularly appropriated for the operation of private automobiles by employees of the system. Most of the cars owned privately but operated at public expense, are attached to the claims division.

✦

St. Louis, Mo.—The Missouri Public Service Commission has overruled a motion of the St. Louis Public Service Company for a rehearing on its petition for a permit to operate a bus line from Wellston, Mo., to the Overland Park district in St. Louis County. While the commission denied the company a rehearing, it pointed out that it would have no jurisdiction if the Public Service Company can obtain the necessary local consent for the line. Several sections of the Missouri Motor Bus Act appear to be in conflict, but to date the Missouri courts have not interpreted the various sections of the act. Pending a final decision, the commission has avoided assuming jurisdiction over bus lines as part of an urban system.

✦

New York, N. Y. — Samuel Untermyer, special counsel for the city in rapid transit negotiations, denies that there has been an agreement as to the price to be paid by the city for the rapid transit lines in a unification plan. Mr. Untermyer, in his statement, said: "The negotiations are, in point of fact, further from consummation than they have been in many months."

✦

Fonda, N. Y. — The recently devised plan of the New York Central Railroad to use the properties of the Fonda, Johnstown & Gloversville Railroad, in order that its unification proposals might conform to the demands of the Interstate Commerce Commission, has been approved by the commission. The agreement provides for readjustment of the rate structure prevailing on the interchange of freight traffic and a contract for the use of joint facilities at Fonda. Much difficulty was encountered during the consideration of separating the Fonda's steam from its electric properties under the commission's original order. Under the present agreement, the separation is unnecessary and the Fonda retains its independent status. The two roads believe that the new rate agreed upon will be beneficial to shippers.

✦

Louisville, Ky.—Recommendations for reductions in wages paid to officers and employees of the Louisville Railway are made in a report to the directors by a special committee of that body.

✦

New York, N. Y.—A monthly magazine, *Traffic Regulation*, devoted to street and highway traffic problems, edited by William Gruen with offices at 114 East 32d Street, has been established as a medium of exchange of discussions of traffic problems.

✦

Washington, D. C.—In order to prevent traffic congestion caused by the parking of interstate buses in downtown Washington, the Public Utilities Commission and the Commissioners of the District of Columbia have embarked on a program to force the bus lines to construct one or more union bus terminals. According to present plans, the police powers of the city will be invoked to route the bus lines through less congested areas. Thus it is believed that the bus lines will be induced to construct terminals and waiting rooms.

News Flashes for the Industry

TO SUPPLEMENT the service of the regular monthly issues of ELECTRIC RAILWAY JOURNAL, a separate NEWS service appears on 39 Saturdays during the year. This supplement keeps you in touch with fare increases, court decisions, association meetings, financial and corporate news, equipment purchases, changes in personnel.

Profitable Meeting Is Held by Iowa Operators

Concentrating on the problems among the most important for the industry to solve, the Operators' Section of the Iowa Electric Railway Association, 100 strong, in convention at Des Moines on Oct. 29 and 30, spent a valuable period. Among subjects discussed were fare collection, operating and maintenance problems, better service and its sale, the trolley bus, railway lubrication, stores accounting, improved transportation units, and bus operating costs. As an innovation, each manufacturer representative was allotted five minutes to express his ideas on "how to do the job better."

Frank V. Skelly, of the Des Moines Railway, chairman of the executive committee of the section, introduced Mayor Crouch who characterized the convention as a commendable co-operative endeavor in the advancement of the science of transportation. Kirk J. Keith, Des Moines Railway, then presided as chairman.

John F. Ohmer, Ohmer Fare Register Company, showed how the selling problem for the railways had changed, and emphasized the need for extensive analysis, research and experimentation. He analyzed the cost of operating taxicabs, buses, private automobiles and street cars, and pointed out that advertising should stress the economy of the street car ride more than other objectives. Mr. Ohmer said the zone fare system permitted transportation to be sold at an attractive price to people who wish to travel short distances. He recited results obtained in Cleveland.

In developing the unusual subject "Stumps in the Field," Henry Cordell, Chicago, North Shore & Milwaukee Railroad, told of ways and means of solving major problems which confront operating men. Among the "stumps" mentioned were pessimistic employees, neglected painting, deferred repairs, slow schedules, inadequate lubrication of journals, babbitts with faulty bases, poor contacts in electrical circuits, leaky slide valves in air-brake systems, improper center plate lubrication, insufficient wheel and axle inspection, unattractive equipment, troublesome water supply for hot water heaters, and unsatisfactory current collection. He stressed advantages of using the sliding collector and polishing the trolley wire.

Laurence Wingerter, Des Moines Railway, told of the problems and difficulties of his company in the past and related the accomplishments by the new management, including complete conversion from two-man to one-man operation, the purchase of 50 new cars, remodeling of 101 old cars for one-man operation, speeding up schedules, improving the power system, effecting major economies, adopting new trainmen's uniforms, installation of a new transfer system and establishment of a new publicity department. Mr. Wingerter told of the many efforts to merchandise the service and to improve public relations.

W. J. Clardy, Westinghouse Electric & Manufacturing Company, discussed the trolley bus comprehensively from the important standpoints of application, performance, maintenance, operating costs and advantages, supplementing his analyses with facts and data on the Chicago, Salt Lake City and Detroit installations. He also compared in detail figures of the street car, trolley bus and gasoline bus for both light and heavy traffic.

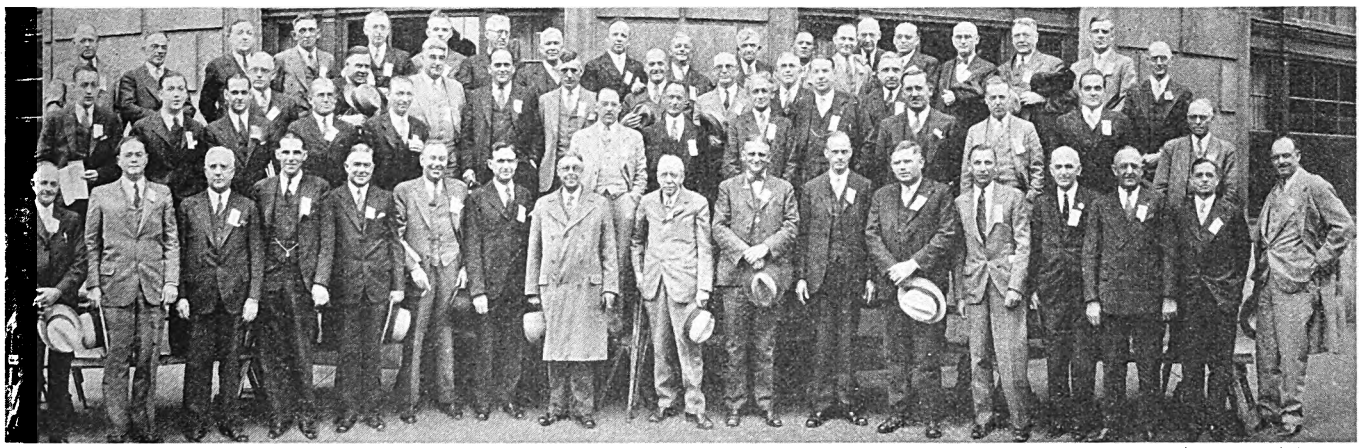
R. S. Neal, Texas Company, said developments in the lubrication of motors, journal boxes and bearings had aided materially in reducing car maintenance costs. Objectives sought are reduction of power consumption, maximum economy of oil, elimination of time and expense for waste saturation and reduction of shop work on bearings and journals. One of the main problems, he pointed out, is to maintain an oil film between bearing surfaces, changing solid friction to fluid friction, and to do this with an oil in which the internal friction of the oil itself can be kept down. Mr. Neal told of the tests made in Baltimore with oil seals and low-viscosity oils, and reported the satisfactory results obtained.

During the past fifteen months, the Des Moines Railway decreased its stores account approximately 27 per cent, employees 50 per cent, and wages 41 per cent, according to G. H. Brown, purchasing agent of the company, in his paper on "Stores Accounting." Although these savings have been accomplished mainly by the adoption of the four to five turnover per year plan on all articles excepting emergency stocks, several other factors have entered. Complete and accurate records must be kept, materials must be classified properly, the storage system must be effective, and procedure for handling requisitions must be logical.

In "New Units for Transportation," C. Dorticos, General Electric Company, told of recent developments in equipment for street cars and described in detail certain of new products. Among the developments he listed are controller units with a larger number of points, automatic control, adaptable for foot as well as hand operation, quick application and release valves, magnetic track brakes, motors with greatly improved commutating characteristics to handle the higher accelerating current necessary for increased speed, twenty lamps in series for improved illumination and low voltage cut-out lamps. In concluding, Mr. Dorticos told about several applications of this modern equipment.

In analyzing the costs of operating buses in city service, D. D. Bentzinger, Iowa Southern Utilities, discussed factors that influence the figures. Among these are operating speeds, accidents, braking, tires, shop equipment, maintenance, uniform gasoline, oil reclaimers and depreciation. In the operating report for the Burlington fleet of 29 25-passenger buses, for the period of July, 1929, to July, 1930, Mr. Bentzinger gave costs per bus-mile as follows: roadway, .010 cent; equipment, 2.348 cents; gasoline, 2.051 cents; conducting transportation, 7.467 cents; traffic, .008 cent; general and miscellaneous, .369 cent; depreciation, 3.00 cents; and total costs, 15.523.

On the first day delegates were entertained at luncheon by the Des Moines Railway. At the annual banquet in the evening C. W. Gifford, general manager of the Des Moines Railway, was toastmaster. The entertainment program was elaborate. On the second afternoon the delegates inspected the new cars and the shops at Des Moines.



Delegates to Iowa Operators' Convention held at Des Moines

Coming Meetings

Jan. 8—Society of Automotive Engineers, annual dinner, Hotel Pennsylvania, New York, N. Y.

Jan. 19—Society of Automotive Engineers, annual meeting, Book-Cadillac Hotel, Detroit, Mich.

Jan. 22-30—Central Electric Railway Association, Claypool Hotel, Indianapolis, Ind.

Jan. 29-30—Central Electric Railway Accountants Association, South Bend, Ind.

April 8-9—Central Electric Railway Master Mechanics Association, Hotel Secor, Toledo, Ohio.

April 16-18—Annual State Convention, Missouri Association of Public Utilities, Excelsior, Mo.

$2,177,000 Equipment Issue Offered

Drexel & Company, Philadelphia, Pa., offered for public subscription on Nov. 24 at prices ranging in return from 4 per cent for the May 1, 1931, maturities to 5.25 per cent for the June 1, 1940, maturities $2,177,000 of Electric Railway Equipment Securities Corporation 4½ per cent equipment trust gold certificates dated Dec. 1, 1930. The certificates will be certified by Fidelity-Philadelphia Trust Company, Philadelphia, as trustee, and will represent less than 75 per cent of the cost of standard electric railway cars and their electrical and other equipment, the remainder having been paid in cash. Title to the equipment will be vested in the trustee for the benefit of the certificate holders. The equipment has been leased at rentals sufficient to pay these certificates and their dividend warrants as they come due. These leases and agreements and the notes representing rentals thereunder due from the various lessee companies will be assigned to the trustee.

The General Electric Company, Westinghouse Electric & Manufacturing Company and the J. G. Brill Company own all of the capital stock of Electric Railway Equipment Securities Corporation, which will unconditionally guarantee rentals sufficient to pay the certificates and their dividend warrants as they come due.

The equipment trust certificates cover a total of 163 cars, distributed as follows: 100 to United Railways & Electric Company, Baltimore, Md.; 40 to Des Moines Railway; 10 to Fitchburg & Leominster Street Railway; 7 to Rockford Public Service Company; 4 to Kansas City, Kaw Valley & Western Railway and 2 (oil-electric) to Hoboken Shore Railroad, a switcher.

*The three index numbers marked with an asterisk are computed by Mr. Richey, as follows: Fares index is average street railway fare in all United States cities with a population of 50,000 or over except New York City, and weighted according to population. Street Railway Materials index is relative average price of materials (including fuel) used in street railway operation and maintenance, weighted according to average use of such materials. Wages index is relative average maximum hourly wage of motormen, conductors and operators on 136 of the largest street and interurban railways operated in the United States, weighted according to the number of such men employed on these roads. †Revised to 1930 Census. See explanation page 756.

Montreal Rapid Transit

(*Continued from Page 771*)

on civic problems, since I have been Mayor of Montreal." He suggested that the address be printed in pamphlet forms in French and English, and distributed to leading organizations.

In a lengthy address, Mr. Watt tendered his hearers a comprehensive ambitious review of the city's transportation and traffic problems, and entered into a detailed discussion of the necessity for subways. The title of his address was "Should Montreal Build Subways Now?" His conclusion—and it was emphatically that of the Montreal Tramways and of leading engineers—was "Yes." He cited authorities to show transit was the first fundamental in the growth of a city, and that the problem could be met in two ways:

1. By important expropriations, which will provide additional streets, or widening of existing streets, to carry the traffic, not only of tramways, but also vehicular and pedestrian traffic.
2. By placing a portion of the traffic underground thereby releasing the streets for the balance of traffic, or, in other words, building subways.

In regard to expropriations, he stated:

It must be borne in mind that the providing of additional streets will not help the problem unless, at the same time, grade separation is provided at the junction of the principal arteries. For example, it will not assist traffic moving north to widen St. Urbain to 80 ft., and still force the traffic to stop at St. Catherine, Ontario, Sherbrooke and Pine Avenue to allow the east-west traffic to flow. Either St. Urbain would have to go underground or overhead at these streets and the same would be true of other main north-south thoroughfares. Therefore in considering the question of expropriations we must, at the same time, consider the question of grade separations.

Subways constituted the second remedy, Mr. Watt stressed, outlining the previously mentioned proposals for north and south-bound and east and west-bound subways, and the branch line. The estimated cost was $65,000,000 and the first question was: "How is the $65,000,000 to be raised, and from what source will the revenue be obtained to pay the interest and the sinking fund, which would amount, at the outset, to approximately $3,500,000 annually?"

EXHAUSTIVE PRESENTATION OF CASE

Supposing that the question was approved and it was decided to spend $65,000,000, necessitating an additional annual revenue of $3,500,000, the best way to obtain this amount, according to authorities (and Mr. Watt cited many), would be to distribute costs in three ways:

1. A share paid by the users of the service.
2. A share from the general revenues of the city.
3. A share by the property owners adjacent to the subways.

In regard to methods of payment, he first considered No. 3, payment of a share of the cost by property owners adjacent to the subway, stating that the history of subways in other cities establishes that immediately a subway was decided upon, property adjacent to it increased in value.

He said that if the fares were raised 1 cent, it would mean an additional revenue of slightly more than $2,500,000. If, instead of selling four tickets for 25 cents, seven tickets were sold for 50 cents, the annual receipts of the company would be increased by about $2,000,000 immediately. That is, if the fare were increased 1 cent, an amount inconsequential compared to the benefits accruing.

The extent to which Mr. Watt went into the details of the situation is instanced by the fact that the report of his remarks covers 22 typewritten pages.

Pull-Ins and Other Topics Enlivened Middle States Meet

Sixty members of the Middle Atlantic States Equipment Men's Association attended the third annual fall meeting at Ocean View on Nov. 11 and 12. On the first day of the meeting J. S. Dean, engineer Westinghouse Electric & Manufacturing Company, reviewed the work accomplished by the Electric Railway Association of Equipment Men, Southern Properties, in reducing pull-ins and improving maintenance costs. The members present received this talk with great interest and the lively discussions which followed indicated the importance attached to this work. The afternoon was taken up by the presentation of interesting motion pictures. "Modern Trends in Urban Transportation" was presented by L. E. Carter, General Electric Company; "A Treadle Travelogue," presented by A. Frank Paul, National Pneumatic Company; "Car Washing Machine," presented by B. A. Tozzer, Leeds, Tozzer & Company. Discussion followed each presentation.

The question box, composed of questions submitted by members, was discussed during the morning of the second day. Discussion of each of the twelve questions composing the question box resulted in a fruitful exchange of information. Among the problems discussed were vapor-locking in fuel lines, brake lining for motor coach operation, noiseless devices on street cars, waste and oil reclamation, relative merits of bronze axle bearings and iron babbitted bearings, and leaking car roofs. Following the luncheon, many of those in attendance accepted the invitation of T. W. Madison to inspect the Norfolk shops of the Virginia Electric & Power Company. After the inspection, the group was conducted on a sightseeing tour through the government naval base and about Norfolk.

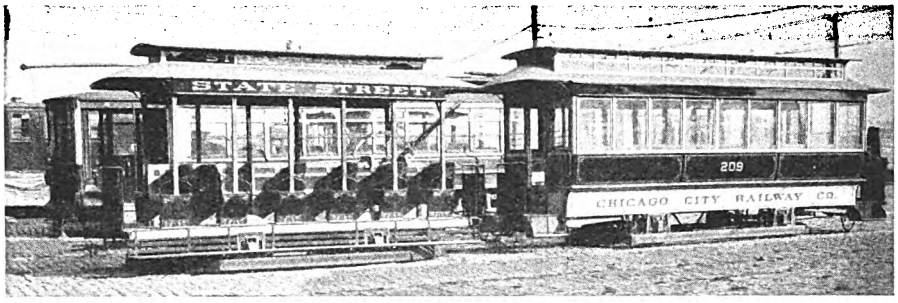
By a unanimous vote, the members accepted the invitation of H. W. McCarthy and R. D. Voshall to hold the next spring meeting in Washington, D. C., on May 14 and 15.

Niagara Falls Fare Increase Agreement Sustained

The Appellate Division of the Supreme Court has unanimously affirmed the order of Justice Staley in the Supreme Court denying an application to restrain the Public Service Commission, the International Railway and the city from entering into a contract for increased fares on local lines of the International Railway in Niagara Falls presaged on a liberal program of improvements.

Under an agreement between the railway and the city, the company was allowed to increase its fare from 5 cents to 8 cents on the basis of two tokens for 15 cents. Labor organizations in Niagara Falls carried the case to the Supreme Court which ruled in favor of the city and the railway. This decision has now been upheld by the appellate division. The order of prohibition was sought on the basis that the City Council should have submitted the proposal to a referendum. It also was alleged the Mayor was not legally entitled to vote to award a contract for increased fares.

The adjustment in Niagara Falls was the subject of review in the JOURNAL for August, page 543.



Replica of Chicago grip car pulling trailer

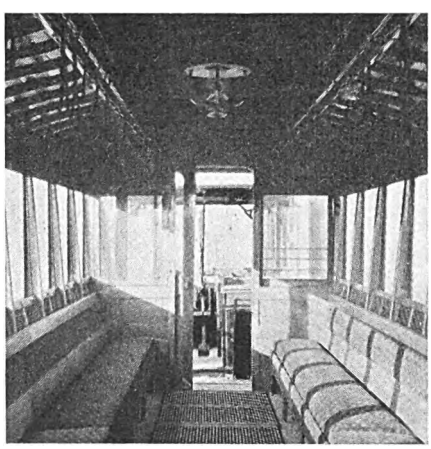
"Old Times" Recalled by Museum Gift of Late L. A. Busby

Part of the exhibit promised by the late Leonard A. Busby, president and director of the Chicago City Railway, to the Museum of Science and Industry, Chicago, founded by Julius Rosenwald, has been completed and will be installed in the transportation division of the Museum when it opens its doors to the public in 1932.

The exhibit will trace the development of urban transportation from its beginnings to the present day. It will, of course, start with the horse car. During the past year a replica of a horse-drawn car has been completed at the shops of the Chicago Surface Lines at 78th Street and Vincennes Avenue. It is completely and faithfully reproduced, from the kerosene headlight to the stove-pipe on the roof. Even the slot has been installed in which the fares were dropped and so rolled down an inclined plane along the length of the car into the fare box just behind the driver.

Another contribution is a replica of a cable-grip car and a trailer which ran on State Street in Chicago.

When Mr. Busby decided to build this exhibit he turned the matter over to Don McGill, superintendent of the shops of the Chicago Surface Lines. Mr. McGill's search for drawings of these old cars proved futile. Finally a photostatic copy of a grip car and train was secured from the Chicago Historical Society. Next there was an "old timers'" conference. Several men in the shops who had repaired cable cars prior to the advent of the electric car made pencil sketches from memory, and point by point the details were worked out. Some one recalled that the bell that had formerly hung about the horse's neck had been transferred to the axle of the cable car. Another remembered that the glass used in the monitor sash was known as "ruby glass" and that on it the words "State Street" were etched. A firm was found and the glass was made. Since horses were used to shunt the cable car from one track to another and to move it into the carhouse, the hooks to which the horses were harnessed were also included in the replica. A huge oil lamp had to be found and the proper kind of carpet to upholster the interior was the subject of another search by Mr. McGill.



An interior view through trailer to grip car

Type of car that ran on Archer Avenue

When both cars were finished Mr. McGill started on his final quest. A horse car is incomplete without a horse, and so, Chicago and its environs were combed to find a horse that would do justice to the exhibit. A papier maché horse was secured, measured for a set of new harness and now awaits installation in a niche in the transportation division of the Museum of Science and Industry.

The accompanying photographs made by its department of photography are reproduced by courtesy of the Museum.

Study of Indianapolis Proposal Planned

Directors of the Indianapolis Chamber of Commerce have announced that its civic affairs committee will inquire into the facts relating to the future operation of local transportation facilities in Indianapolis as involved in the proposed plan of reorganization and refinancing of the Indianapolis Street Railway.

This committee intends to study the recent reorganization proposals, and to inquire into the manner in which service-at-cost franchises have operated in other cities, the rates of fare prevailing in other cities, costs of operation, character of service and other features enlightening to local consideration of the plans. The findings of the committee will be made public.

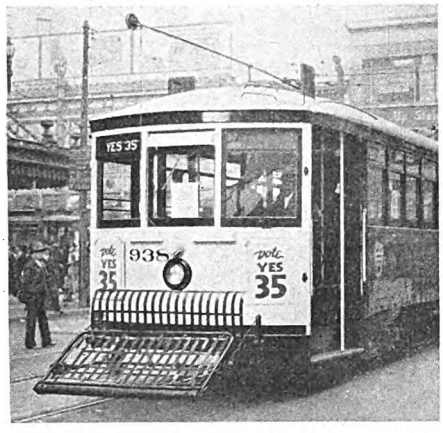
Model San Francisco Car Used in Franchise Campaign

One of the latest model "California Comfort Cars," built in the shops of the Market Street Railway, San Francisco, was used for advertising purposes during the election campaign for a 25-year operating permit for the privately owned companies. The measure was No. 35 on the ballot. The accompanying illustration shows some of the uses the new car was put. Now that the voters have approved the granting of the permit, the company plans to start immediate production of 100 of these new



San Francisco car an effective campaign appeal

cars. This new car is 3½ tons lighter than any previously produced by the company. Gears are leaded to reduce noise and gear boxes are insulated with a special sound deadener, which is also placed under the flooring of the car for its entire length.

Trolley Buses Included in New Springfield Proposal

At a conference held on Nov. 21 between city officials of Springfield, Ohio, and executives of the Cincinnati & Lake Erie Railroad, H. C. Donecker, vice-president, presented the outline of a transportation system practically equivalent to that now in operation which contemplates retention of the present rate of fare for an indefinite period. The new proposal includes the elimination of two minor divisions which have been operating at a loss, the part-time operation of trolley buses on two other lines, and increases of service and headway on four other divisions which have been making a profit.

The tentative plan of routing met with the approval of Clyde E. Wallingford, city manager, and the five city commissioners, who also approved the retention of the present rate of fare. The company is seeking a new grant and has been invited by the city to submit a tentative franchise embodying the routes suggested and other details. City officials want to conclude the negotiations in order to proceed with paving.

FOREIGN NEWS

British Borough To Test Two Types of Trolley Bus

The County Borough of Walsall, England, has decided to install a trolley bus system at an estimated cost of $33,910. Service will be started with four trolley buses of two different types. Two of these will be A.E.C.-English Electric double-deck, low-loading buses driven by direct-current 80-hp. engines, and equipped with Westinghouse brakes, while the other two will be Guy trolley buses equipped with motors of the regenerative type.

The object of ordering two vehicles of each kind is to enable the corporation, if and when it decides to extend its trolley bus operations, to choose between these two types of machines.

Details of the A.E.C.-English Electric model indicate that the most distinctive feature of its design is the placing of the motor in front of the chassis so that practically the whole of the electrical equipment is centralized in or close to the driver's cab. Ease of access is insured by a removable louvre panel.

British Transport Minister Modifies Public Control Idea

At a staff dinner of the London Underground Railway combine recently, Herbert Morrison dealt with the Government's plans regarding London passenger transport. Mr. Morrison said that suitable measures would be included in the London traffic co-ordination scheme to secure fair treatment for the officers and employees of the undertakings to be taken over by the public body. He said:

The old idea of the provision of London traffic facilities is to leave it to individual competitive undertakings to find out public needs and, if meeting these needs is thought to be a profitable enterprise, to enter the field. It was also thought sound that if other private undertakings also started services in competition this meant plenty of transport and lower fares. We have now come to realize, particularly in cases like the Greater London area, that it is necessary to regard passenger transport as a whole, to see that the service is adequate and effective to meet public needs, and at the same time to avoid the provision of wasteful services and commercial failure.

Despite the measure of consolidation which now exists in London passenger transport, there is plenty of room for further co-ordination. The choice really lies between a huge private monopoly and some form of co-ordinated public service. In the important negotiations on which I am entering I have every hope of securing the good will not only of the general public, but of those private and public undertakings engaged in providing passenger services in Greater London.

Trolley Bus for Lancashire

In Lancashire, the South Lancashire Transport Company is planning a course of future expansion different from that which will probably be followed in Liverpool. This company, which operates a widespread system over a densely populated area, has begun a change-over to the trolley bus, chosen in preference to a bus service—the medium hitherto adopted by the majority of municipalities and railway undertakings which have had cause to change their method of transport.

✦

Johannesburg, South Africa — The general manager of the Johannesburg Municipal Electricity Department has prepared a report which recommends the use of trolley buses in certain sections of the city. It is suggested that expenditures on the tramway system be reduced to a minimum and that, where possible, the trolley bus be used. The system now consists of 84 miles of permanent way, with 198 cars. The total capital expenditure on the system, as of June 30, 1929, was £1,379,121. At present 38 gasoline buses are run.

Christmas Shopping Pass for 75 Cents in Milwaukee

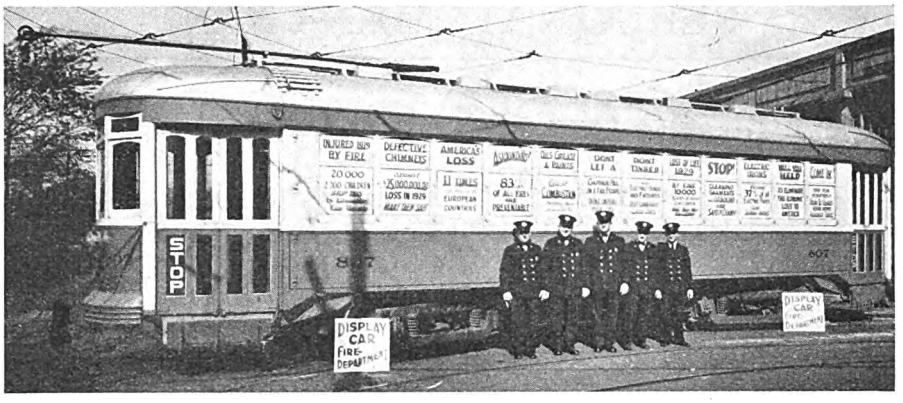
To stimulate Christmas shopping and to encourage riding during non-rush hours, the Milwaukee Electric Railway & Light Company will sell a special Christmas shoppers' weekly pass for 75 cents. The new pass will be valid on all street car and auxiliary bus lines in the single fare area and will be transferable. It will supplement the unlimited $1 weekly pass. The special pass will be in effect for five weeks, beginning Nov. 30. It will be good at all timse except between 5 a.m. and 9 a.m. weekdays, between 4 p.m. and 7 p.m. weekdays, and between 5 a.m. and 9 a.m. Saturdays. It will be good all Saturday afternoon and evening, and all day on Sundays and holidays. President Way said:

We believe that the low fare offered during the holiday season by means of the Christmas special pass will stimulate shopping and tend to hasen the return of normal business conditions. We also hope it will increase street car riding in the non-rush periods and contribute to the relief of peak hour traffic congestion. During the holiday shopping period the riding by shoppers tends to overlap the riding of office and industrial workers. This results in inconvenience and delays to all users of the service.

Passes will be available for purchase on street cars and buses. They will also be available at the company offices and car stations, and at the Boston store, Gimbel's and the three Schuster stores. Use of the special pass will be discontinued automatically after Jan. 3.

New York Substitution Plea Amended

The New York City Omnibus Corporation, subsidiary of New York Railways Corporation, has filed with the Board of Estimate a supplement to its original application for franchises to operate buses on seven crosstown lines, asking for franchises to operate nine more lines in the Borough of Manhattan. The plan amounts to motorization of the entire New York Railways system. The application proposes that on all but two lines, the company will charge a 5-cent fare. The other two lines, are divided into two 5-cent zones. A charge of 2 cents will be made for transfer at intersections.



Fire prevention car with members of local fire department in charge

Fire Prevention Demonstration at Harrisburg by Trolley Car

"Fire Prevention Week" at Harrisburg, Pa., meant more to the Harrisburg Railways than mild participation on its part in the event. And the accompanying illustrations substantiate this statement. Through a car offered to the local fire department for display purposes and through the co-operation of that department, local Chamber of Commerce, Pennsylvania Power & Light Company and the Harrisburg Gas Company, together with the district officers of the Fire Underwriters Association the exposition program was brought to the attention of the people of Harrisburg and surrounding towns.

The car was on display in what is known as Market Square, Harrisburg, daily, from 11 a.m. to 1:30 p.m. and from 5 p.m. to 10 p.m., and at such times was in charge of assigned members of the Harrisburg fire department who conducted visitors through the car and explained the various displays.

During the week, and at times when not on display at Market Square, the car was routed to the outlying communities as well as the various schools and at each of these points the attendance was quite large. The method of display received a considerable amount of favorable comment from the local newspapers. Fire department records showed nearly 15,000 people boarded the car and examined the various displays. These consisted of numerous exhibits of electrical equipment of a fire-hazard type, modern methods of electrical installation, obsolete and modern fire prevention equipment, hazardous and safe brick chimney construction, modern fire alarm boxes and other features designed to educate the public in fire prevention. One of the modern fire alarm boxes being installed throughout the city was so hooked up with a fire gong in the car that actual demontrations were made for the benefit of visitors to show how to turn in an alarm in case of a fire.

Timely Tax Text

Under the title "The Tax that Breaks the Street Car's Back," Leslie Vickers, economist American Electric Railway Association, has contributed a timely analysis of street railway taxation to the Nov. 27 issue of *Public Utilities Fortnightly.* To street railway operators the fact that their properties are loaded with tax burdens, is no secret. The general public, however, knows little of the situation. Mr. Vickers' article helps to throw light upon this.

PERSONAL MENTION

Segregation of Ohio Rail and Bus Lines Announced

Messrs. Sammis, See and Graham Appointed to Chief Executive and Operating Posts With Transportation Securities Corporation, Successor to Transportation Lines of Ohio Edison Company

A. C. BLINN, vice-president and general manager of Ohio Edison Company, announced on Nov. 15 that Ohio Edison Company had sold all of the common stock of Akron Transportation Company, Northern Ohio Interurban Company, Canton Traction Company and the Cleveland-Akron-Canton Bus Company to Transportation Securities Corporation. By this sale, Ohio Edison disposes of its entire interests in the transportation business and hereafter will be engaged exclusively in the electric and steam heating business. Mr. Blinn and L. G. Tighe, vice-president and Akron Division manager of Ohio

W. H. Sammis

Edison Company, who have been officers of the transportation companies, retire as such and neither they nor any of the employees of Ohio Edison Company as now constituted will hereafter have any connection with the transportation business.

Transportation Securities Corporation is headed by W. H. Sammis, New York, as president; R. N. Graham, Youngstown, as vice-president; P. V. C. See, Akron, vice-president and general manager; J. B. Waring, Akron, is secretary and treasurer, and W. O. Zehm, Akron, auditor.

In addition to Messrs. Sammis, Graham and See, the directors are D. A. Scanlon, formerly general superintendent of railways of Northern Ohio Power & Light Company, as transportation superintendent; W. J. Ruof, vice-president Central-Depositors Savings & Trust Company; W. A. M. Vaughan, vice-president of the First-City Trust & Savings Bank, and E. A. Oberlin, president Firestone Trust & Savings Bank, all of Akron.

Mr. Sammis has recently been connected in New York with the Commonwealth & Southern interests, which control the systems in Ohio. Among his other work there he has been assistant to T. A. Kenney, vice-president of the Allied Power & Light Corporation. He was at one time with the Consumers Power Company in Michigan. Also for a time he was an instructor in electrical engineering in Columbia University. He joined the power staff of the Charles H. Tenney Company in 1924, but previous to that he had been connected with the Public Service Electric Company and the Brooklyn Rapid Transit System. From 1917 until the fall of 1929 he was in the United States Naval service. He was graduated from Columbia and has written frequently on technical subjects, notably a treatise on aircraft ignition equipment.

Operating Officials of Wide Experience

Mr. See has been engaged in the transportation business for many years. He is a graduate of Armour Institute of Technology from which he later received an advanced degree in electrical engineering. He had his early training as car building inspector and foreman with the Chicago Elevated Railways. He was also general foreman for the Twin City Rapid Transit Company, St. Paul, Minn. He next became general foreman for the Illinois Traction System at Decatur, Ill. Mr. See next went to New York and for eleven years was superintendent of equipment for the Hudson & Manhattan Railroad operating between New York and New Jersey. His experience has thus covered every phase of transportation—city and interurban, elevated and subway cars, buses, truck and automobiles. At present he is first vice-president of the American Electric Railway Engineering Association. He has been active in the work of the master mechanics group affiliated with the Central Electric Railway Association, as well as the national association.

R. N. Graham

He is now and has been a member of the transportation and maintenance committee of the Society of Automotive Engineers. He has been engaged in transportation work in Akron for the last ten years as superintendent of rolling stock and equipment.

Like Mr. See, Mr. Graham has made many notable contributions to the art of mass transportation. He has been a frequent contributor to the technical press, and his papers and discussions before national and sectional associations have been especially welcome for the wealth of information they have contained. He played his part in securing the award of the Coffin medal to the Penn-Ohio system and scored again last year in the winning of that award by the Youngstown Municipal Railway. He is a lawyer turned railway man, going to Youngstown in 1917 to manage the railways of the Mahoning & Shenango Railway & Light Company. He was born in Jackson, Mich., in 1877, and was graduated from the University of Arkansas with the class of 1898. He then practiced law in Joplin, Mo., until 1908, and during this time served as a member of the Missouri Legislature from the Joplin district. Mr. Graham entered the electric railway field through a connection of several years with the legal department of the Houston Electric

P. V. C. See

Company and the Galveston-Houston Electric Railway, Houston, Tex. In 1916 he was made assistant manager of railways of the Mahoning & Shenango system in charge of the railway properties. While Mr. Graham practiced before the bar his work in Missouri, Kansas, Oklahoma and Texas dealt largely with municipal and corporation problems.

D. A. Scanlon has been general superintendent of railways for many years for the Northern Ohio Power & Light Company. He has been retained by the new transportation organization as superintendent.

Transportation Securities Corporation, the purchaser of the stock ownership of the transportation companies sold by Ohio Edison Company, is a holding company which now owns the common stock of the street and interurban railway and motor bus companies operating in Youngstown and other communities in eastern Ohio and western Pennsylvania.

The plan of organization of the Ohio Edison Company and a statement of its personnel were the subject of review in Electric Railway Journal for August, 1930, page 545.

Railway Official Heads West Virginia Operators

C. H. Hardesty, recently elected president of the Public Utility Association of West Virginia, is vice-president of the Monongahela-West Penn Public Service Company in charge of generation, distribution and sale of electricity for the company, which now furnishes various types of public utility services in 27 counties in northern West Virginia; Washington and Noble Counties, Ohio; Garrett County, Md., and Fayette County, Pa.

Mr. Hardesty has literally come up from the ranks. Having worked in numerous departments on several divisions, Vice-President Hardesty has a wide acquaintance among employees. Outside the company, too, he is known as one of the able utility executives of the country, and at present is president of the East Central division of the National Electric Light Association, which includes the states of West Virginia, Ohio and Kentucky.

Mr. Hardesty was born in Marion County, and after he was graduated from West Virginia University he was employed by the Western Maryland Railroad from 1915 to 1917. His first work with the company was in the purchasing department where he started Dec. 27, 1917. He was appointed superintendent of the Clarksburg division on May 1, 1920. Other

C. H. Hardesty

positions he has held include traveling freight and passenger agent, general traffic manager, manager of the Parkersburg and Marietta division, and assistant to the president. Mr. Hardesty was appointed vice-president in charge of electrical production and sales on Feb. 6, 1929.

Twenty Year Club Has Distinguished Member

Honorary membership in the Twenty Year Club of the Indianapolis Street Railway has been conferred upon Louis Ludlow, representative in Congress from the Seventh Indiana district. Mr. Ludlow was in newspaper work and was political correspondent at Washington for numerous publications prior to his election to the House of Representatives. As the principal speaker at the club's annual dinner and meeting, he related humorous incidents in his early experience with the railway and its employees while he was in newspaper work in Indianapolis twenty years ago. Beck Lowe, an employee in the shops department, received a testimonial belt awarded each year to the employee with the best service record. He has been employed by the company for 50 years.

New Jersey Railway Operating Officials Are Advanced

Philip F. Maguire Made Superintendent Maintenance of Way in Transport—Thomas P. Burke Becomes Manager and George Klement Assistant in Central Division

P. F. Maguire

ANNOUNCEMENT has been made by Vice-President Matthew R. Boylan, Public Service Co-ordinated Transport, Newark, N. J., of the appointment of Philip F. Maguire to be superintendent of maintenance of way, to succeed the late Martin White. Mr. Maguire, who has been manager in the central division, will be succeeded in that position by Thomas P. Burke, formerly assistant manager. George Klement has been named assistant manager in the central division.

Mr. Maguire has been central division manager since November, 1925, and superintendent of that division for six years prior to 1925. He has been in the continuous employ of Public Service and predecessor companies more than 34 years. He has risen, step by step, to his new position from the platform of a street car, for in August, 1896, he started with the Plainfield Street Railway as a conductor. In 1899 he was promoted to inspector at Plainfield, and in 1903 was made supervisor in charge of the Union line, Plainfield lines and the Rahway line. To familiarize himself with the work of the department of which he now becomes superintendent, Mr. Maguire was transferred to the maintenance of way department in April, 1906, and became assistant superintendent of that department in 1915. He

T. P. Burke

remained there until 1919, when he was promoted to superintendent of the central division.

Mr. Burke has held various positions in transport work with Public Service and was stationed in Perth Amboy, Westfield, Plainfield, New Brunswick and Newark. He began his career in transportation work in 1894, at Bridgeport, Conn., in the employ of the Radel Brothers, who also owned the Middlesex & Somerset Traction Company in New Jersey to which they transferred him in 1900, as an inspector at Bound Brook. When Public Service acquired the Raritan Traction Company in 1904, Mr. Burke was sent to Perth Amboy to take charge. In 1905 he was appointed supervisor in charge of Plainfield and Westfield lines. In 1906 he was appointed supervisor of all lines operating out of New Brunswick, where he remained until

G. Klement

1918, when he left Public Service to take another position. In 1925 he returned to Public Service and was assigned to Essex division. He was supervisor at Miller Street carhouse and Sherman Avenue garage in Newark just prior to his promotion in March, 1927, to assistant manager of central division, one of the system's largest.

Mr. Klement began his association with Public Service in April, 1915, as a conductor at Miller Street carhouse. He then served for two years on the "Fast Line," operating between Newark and Trenton. He was appointed stationmaster at Miller Street in 1919, and held this position for seven years. In 1926 he became road supervisor at Central Avenue carhouse, later holding a similar position at Big Tree, Roseville and Hilton carhouses. He has recently been Bloomfield district superintendent, Essex division.

Raymond S. Tompkins, assistant to the president of the United Railways & Electric Company, Baltimore, has been elected to the board of directors of the Better Business Bureau of the Advertising Club of Baltimore.

Honolulu Official in Elective City Office

Leroy C. Bush, chief engineer of the Honolulu Rapid Transit Company, Ltd., Honolulu, Hawaii, was elected a member of the board of supervisors of the city and county of Honolulu at the general election on Nov. 4. This was Mr. Bush's first attempt at politics. He not only lead the Republican ticket in the primary election, but received more votes than any of the many other candidates in the general election. As the supervisors in Honolulu devote only part time to city work, the election will in no way interfere with his duties with the local railway. He will be chairman of the important public works committee of the supervisors.

Mr. Bush entered the employ of the Honolulu Rapid Transit Company in April, 1922, as assistant engineer in the maintenance of way department. His promotion with the company was rapid. He assumed his present position in February, 1928. He was born in Honolulu on Dec. 1, 1897, and attended public schools there. In 1920, he was graduated from the University of California with a degree in mechanical engineering. After taking the student engineers' course at the Allis-Chalmers plant in Milwaukee he returned to Hawaii.

G. R. Green Vice-President as Well as Manager

George R. Green, general manager of the Northern Indiana Railways, Inc., South Bend, has been elected vice-president of the organization. He succeeds Harry Wair, South Bend attorney, who recently died.

Two new directors have also been elected. They are Arthur L. Hubbard, president of the First National Bank, South Bend, and Allison E. Stuart, Lafayette, Ind. Mr. Hubbard fills the place on the board of directors left vacant by the death of Mr. Wair, and Mr. Stuart occupies a position that has not been filled since the corporation was reorganized last year.

The board of directors of the Northern Indiana Railways, Inc., now consists, in addition to Mr. Hubbard and Mr. Stuart, of Alfred P. Dietrich, New York City; A. H. Plumb, Emporia, Kan.; R. R. Smith, South Bend; Alva Kitselman, Muncie, Ind.; and W. C. Ewen, New York City.

The officers are Mr. Smith, president; Mr. Green, vice-president and general manager, and O. A. Small, secretary-treasurer.

Herbert C. Lummis Retained in Washington

Services of Herbert C. Lummis, an engineer of wide experience on many properties in different parts of the country, have been retained by the Capital Traction Company, Washington, D. C., in connection with the valuation of its property now being made by order of the local Public Utilities Commission. Mr. Lummis has already taken over his new duties and will have charge of this work under President J. H. Hanna.

For six years Mr. Lummis was staff engineer of the board of supervising engineers in Chicago, which has supervision over the surface lines of that city. Recently he has been engaged as a consultant in valuation and rate cases, rapid transit routes and leasing street railway routing, etc. in Philadelphia, New York, Montreal, Washington and Buffalo.

Mr. Lummis was born in Georgia, educated in the public schools and received his degree in Civil Engineering in 1912 from the University of Colorado. After he was graduated, his first connection was with Bion J. Arnold, Chicago. He was an assistant engineer in the study of the transportation facilities of San Francisco in 1913 made for the city by Mr. Arnold.

While on the Arnold staff Mr. Lummis made reports on routings, rapid transit plans, entered into financial and accounting studies and engaged in other urban transportation work of similar character in most of the large cities of the country. He was principal assistant engineer in the valuations of the surface system of the Brooklyn Rapid Transit Company. He also had charge of the valuation of the Aurora, Elgin & Chicago Railway in 1919.

Tudor W. Jones, auditor of the Indiana Railroad, Anderson, Ind., formerly the Union Traction Company of Indiana, has resigned his position. He was connected with the Union Traction Company for 25 years, having started as ticket agent at Anderson in 1905. For the past nine years he has been auditor of the company. Mr. Jones expects to devote his attention to other interests after a brief vacation. No successor has been named to fill the position.

A. J. Lundberg Heads Revamped Oakland Transportation System

A. J. Lundberg

A. J. LUNDBERG, who heads the reorganized Key System Transit, Oakland, Cal., entered that company as a representative of banking interests when the affairs of the railway seemed darkest several years ago. His announced intention was to restore the company's credit and put its securities on a sound basis. That task proved insuperable without reorganization, and the readjustment was carried out recently. In some respects it has been drastic but no more so that the changed economic conditions under which the company is now forced to operate seemed to make desirable. As a result there has been evolved the East Bay Street Railways operating the street railway lines, the East Bay Motor Coach Lines operating the bus lines, the Key System operating the transbay service and the Key Terminal Railway operating the ferry services. Stock of these companies is held by the Railway Equipment & Realty Company, with Mr. Lundberg at its head, as he is of the subsidiary companies, except the Terminal Company.

As just indicated, Mr. Lundberg took over the administration of the old transit company when it was in a precarious financial condition. He headed a new management that represented in many respects a complete change in company policies. The reorganization of the old Key's tangled affairs could not be avoided, but the readjustment was unusual in many respects. In spite of its size and the number of security holders involved, the costs of the readjustment were low. The members of the readjustment committee, without compensation, assumed the responsibility involved and devoted their time to the many meetings and discussions. Due to the co-operation of many financial institutions, no expenditure was incurred for the solicitation of security holders other than the preparation and mailing of literature. Under the plan which was finally put into effect, the funded debt of the old transit company was reduced from $20,000,000 to $4,500,000, all of which is in the form of equipment trust certificates.

Although primarily a banker, Mr. Lundberg brought to the Key System an uncanny sense of values. He was keenly alive to the economic changes in transportation, and he and his associates left no stones unturned, so far as it was possible, to merchandise the service. But he didn't overlook economies. He faced the problems firmly as they arose and when the time came for financial readjustment he was just as thorough in his housecleaning as he had been in his efforts to rehabilitate the property physically and from the point of selling the service more intensively.

Primarily a Banker

Mr. Lundberg's first business connection was with the Bank of San Francisco, which later was absorbed by the Bank of Italy. He entered the employ of the bank in 1909, and in 1910 became an employee of the state banking department under Alden Anderson, superintendent of banks. A year later he became secretary to Herbert Fleischhacker of the Anglo and London Paris National Bank in San Francisco, remaining in that capacity until 1912. In the latter year he accepted a clerkship in the brokerage firm of J. Barth & Company in San Francisco, becoming a partner in that concern in 1926.

Mr. Lundberg was born in San Francisco. He received his education in the public schools of his native city. He was the first president of the San Francisco Stock and Bond Exchange.

Col. R. H. James Indiana Operating Executive

Col. Ralph H. James, vice-president of the Chicago, South Shore & South Bend Railroad and Chicago, North Shore & Milwaukee Railroad, has been elected vice-president in charge of traffic of the Indiana Railroad. Robert M. Feustel, president of the Indiana Railroad, made the announcement. Mr. Feustel also announced the election of William J. Knorst as assistant vice-president, and Edwin J. Booth, as assistant to the president.

As vice-president in charge of traffic of the Indiana Railroad, which formerly was the Union Traction Company of Indiana, Colonel James will be chief traffic executive of the entire Indiana Railroad System. He will be assisted by Mr. Knorst.

The Indiana Railroad System includes the electric interurban railway lines of the Indiana Railroad, Interstate Public Service Company, Indiana Service Corporation and Northern Indiana Power Company, comprising a total of more than 700 miles of track.

Colonel James served in the World War as an officer in the British army.

J. C. McPherson in New Southern Pacific Post

J. C. McPherson, for the past eight years superintendent of the East Bay electric division of the Southern Pacific Company, has been made general representative of the organization with headquarters in Oakland, Cal. This appointment followed the consolidation of the East Bay Electric and Western divisions of the Southern Pacific. He will represent the operating department in public relations in the East Bay cities and have charge of the company's real estate in Alameda and Contra Costa Counties.

Mr. McPherson entered the employ of the Pacific Electric Railway at Los Angeles in 1895 as a conductor, and advanced until he became superintendent of the northern division of the electric system. In 1913 he was appointed to take charge of the Oakland, Berkeley and Alameda electric lines. Following the war, he returned to the Pacific Electric in 1919 as assistant general superintendent, which position he held until he again took charge of the East Bay electric lines in 1922.

English Editor Appreciative of American Courtesies

Horace Wyatt, director of *Bus and Coach* and *Motor Transport*, published in London, England, has returned home after a visit of more than six weeks in the United States and Canada. Mr. Wyatt came here primarily to attend the International Road Congress in Washington, but, at the conclusion of the sessions of the Congress, he traveled in the East and the Central West to study bus and truck operation. He was a particularly interested observer at the meeting of the transportation section of the Society of Automotive Engineers held in Pittsburgh.

In England the problem of the competition of the private car with the mass transportation agencies is not so acute as it is here, and, as yet, the problem of the parked car has not manifested itself there to anything like the same degree. However, Mr. Wyatt feels that his visit to the United States and Canada has greatly increased his understanding of these problems just as it has his realization of the problem of the pirate taxi.

During his stay, Mr. Wyatt interviewed, among others, many electric railway operators. In discussing his trip with a representative of ELECTRIC RAILWAY JOURNAL, he expressed his appreciation of the many courtesies extended to him here, stressing particularly the degree of candor with which executive officers and officials discussed operating and engineering problems with which they are confronted.

Consulting Engineering Office Opened by A. H. Armstrong

A. H. Armstrong, assistant engineer of the railway department of the General Electric Company for many years, and more recently chairman of the railroad electrification committee, and consulting engineer for the transportation department, has established a private consulting engineering office at 16 Troy Road, Schenectady, N. Y.

A. H. Armstrong

An outstanding authority on electric traction in the United States, he has contributed much fundamental information to textbooks on this subject, as well as exhaustive papers before various technical societies. His numerous studies of railroad electrification projects and, more particularly, his intimate connection with such electrification work as the Chicago, Milwaukee, St. Paul & Pacific, the Butte, Anaconda & Pacific, the New York Central, and other well-known electrifications, have especially qualified him for the consulting work which he is now entering upon in connection with railroad electrification.

Mr. Armstrong was graduated from Worcester Polytechnic Institute in 1891. He entered the employ of the Thomson-Houston Company at Lynn, Mass., in the same year. He joined the railway engineering department of the General Electric Company in 1897, and since that time has devoted most of his energies to the study of railroad problems.

He is a member of the American Institute of Electrical Engineers, the National Electric Light Association, the American Electric Railway Association, the American Railway Engineering Association, and other societies.

George Wright in Charge of Toronto Garages

George Wright, for the past ten years material superintendent of the way department of the Toronto Transportation Commission, Toronto, Ont., has been made superintendent of the garage department. Mr. Wright was born in Halifax, N. S. He was graduated from the Faculty of Applied Science of the University of Toronto in 1907. He spent a year on the staff of the University, a year with the Canadian Northern Railway, three years as assistant engineer of maintenance of way with the Grand Trunk Railway, three years in the City of Toronto Works Department, two years supervising construction with the Warren Paving Company, one year deputy engineer of London, Ontario, three years as city engineer of London. He also served as field engineer on plans in taking over the Toronto Street Railway, after which he spent two years with the department of highways in charge of Eastern Ontario work. Leaving the highways department, he worked in 1920 on the valuation of the property of the Toronto Railway, later taken over by the city, and was then appointed material superintendent of the T.T.C.

W. H. Swift, Jr., at Springfield

William H. Swift, Jr., for four years manager of the New Brunswick Power Company, with 25 miles of electric railway in St. John, N. B., and suburbs, has assumed his duties as manager of the Springfield Gas & Electric Company and the Springfield Traction Company, Springfield, Mo., succeeding A. E. Reynolds, transferred to St. John.

At the time of his departure from St. John, Mr. Swift was tendered a farewell banquet in the Union Club, St. John, attended by 100 men. During the dinner, he was presented a silver cigar and cigarette container, engraved with these words: "William H. Swift, Jr.—from friends and business associates in Saint John, N. B., Canada, Oct. 29, 1930." The presentation was made by the Mayor. There were speeches by the Mayor, Premier of the Province, W. S. Fisher, a member of the board of directors of the New Brunswick Power Company, and by Mr. Swift, and his successor, Mr. Reynolds, Mr. Swift having remained to introduce Mr. Reynolds.

Another Decoration for Arthur Gaboury

The Government of the French Republic has bestowed on Arthur Gaboury, secretary-general of the Province of Quebec Safety League. Montreal, the decoration of "Officier de l'Instruction Publique." This is the second decoration awarded Mr. Gaboury, for in 1918 the French Republic on the recommendation of the "Union Nationale Francaise" of Montreal bestowed on him the "Palmes Académique" for the excellent services rendered by him in the promoting and furthering the cause of French Canada. Moreover, in July, 1908, the "Union Nationale Francaise" presented him with a gold medal as a testimonial to the work done and service rendered to the French cause.

Arthur Gaboury is known throughout

Digitized by Google

the Province of Quebec as the safety standard bearer. As secretary-general of the Province of Quebec Safety League his word on all matters appertaining to safety measures is accepted as final. Created in 1923, the Safety League has grown to an organization covering practically every industrial firm of note in the Province.

Mr. Gaboury entered business with the Montreal Tramways on June 6, 1893, finally becoming head of the claims department. The year 1914 saw the birth of a campaign of accident prevention, a movement that was actually the foundation of what is now known as the Province of Quebec Safety League, organized by Mr. Gaboury when he left the Montreal Tramways. For 1920-1921, Mr. Gaboury was president of the Canadian Electric Railway Association. He also served as a member of the executive committee and Canadian representative of the American Electric Railway Association.

B. C. Palmer Represents Ohmer in Chicago

Complete charge of the Chicago branch of the Ohmer Fare Register Company has been assumed by B. C. Palmer, special sales engineer for that firm since 1927. In addition to supervising the business offices there, and continuing in his capacity of general sales manager for the company's taximeters, cash registers, and recording devices, Mr. Palmer will direct Ohmer activities over a large surrounding territory of eight states.

✦

A. C. Moorhaus, purchasing agent of the Union Gas & Electric Company, Cincinnati, Ohio, since 1924, has been made acting general manager of the company. Mr. Moorhaus became affiliated with the Union Gas & Electric Company six years ago, after resigning as secretary of the Scioto Valley Railway & Power Company, Columbus. W. R. Freeman, assistant to Mr. Moorhaus since March of this year, becomes acting purchasing agent of the Union Gas & Electric Company.

✦

Roy V. Wright, of New York, managing editor of *Railway Age,* has been elected president of the American Society of Mechanical Engineers for 1931. Mr. Wright succeeds Charles Piez, of Chicago. He will be installed at the annual meeting in New York Dec. 1-5. Mr. Wright is a graduate of the University of Minnesota. He has been in railway mechanical work for 32 years.

✦

T. Justin Moore, vice-president and general counsel for the Virginia Electric & Power Company, Richmond, Va., was elected president of the Virginia Public Utilities Association at the closing session of the fifth annual convention of the organization at Virginia Beach, Va., on Nov. 14.

✦

Neill W. Funk, safety director and head of the claims department of the Louisville Railway, Louisville, Ky., who has served several short terms under appointment as police judge of Louisville, recently accepted another appointment for relief duty, but has announced that his judgeship salary would all go to charity.

OBITUARY

Martin White

Martin White, superintendent maintenance of way Public Service Co-ordinated Transport, Newark, N. J., died on Oct. 25. Mr. White began his connection with street railway work some 37 years ago when he took a position as track foreman with the Rapid Transit Street Railway, a predecessor company of Public Service. Since that time he was continuously in the company's employ, achieving the unusual record of holding the position of superintendent of maintenance of way for almost a quarter of a century.

Mr. White was thoroughly versed in the transportation business with which he had been identified many years, and in electric railway circles throughout the country he was known as an expert in the maintenance of way field. Matthew R. Boylan, vice-president in charge of operation, paid tribute in *Public Service News,* company

Martin White

publication, to Mr. White as a close friend and valued counselor over a long period of time and through many struggles. Mr. Boylan said that "he was a true gentleman, in the best sense of that term—product of a school which is rapidly vanishing. His honesty, loyalty and genial nature commanded a host of friends, none of whom will miss him more than we, his Public Service associates."

Mr. White's skill and ability in all matters pertaining to maintenance of way work soon brought him into wide prominence in engineering circles in New Jersey. He was the first to suggest the use of clipped stone block in paving between rails and he contributed many valuable suggestions to the makers of special track work at intersections and railroad crossings.

Born in County Galway, Ireland, in 1859, Mr. White came to this country when he was sixteen years old. Prior to his association with the Rapid Transit Street Railway he worked for some time in the maintenance of way department of the Pennsylvania Railroad.

✦

W. E. Davis

William E. Davis, 67, prominent electrical engineer, died at Cleveland, Ohio, recently. He took a leading part in the building of street railway lines in Toronto, Canada, in the early 1890's and the Lake Shore Electric Railway, in Ohio. He became light and heat commissioner for Cleveland, and in 1923 was made chairman of the arbitration board, established to fix a rate between the municipally owned system and the Detroit United Railway covering terms for interurban cars to operate over the city tracks. For the past few years he has been consultant for the Cleveland Railway.

✦

W. S. Dimmock

W. S. Dimmock, Los Angeles, Cal., long active in the electric railway field, died recently in that city. Much of Mr. Dimmock's work had been done for Stone & Webster on their Pacific Coast properties, notably as manager of the Puget Sound Electric Railway, Pacific Traction Company and the Tacoma Railway & Power Company. Mr. Dimmock began his career in steam railroad work. After long service there he entered the electric railway business in 1892 as general manager of the Omaha & Council Bluffs Street Railway and the Omaha & Southern Railway. Later he served as general manager of the Richmond Passenger & Power Company, operating in Richmond and Petersburg, Va. It was from the Richmond properties that he went to the Pacific Coast for Stone & Webster and there became an important factor in the management of properties over which they exercised supervision. For them he continued in one capacity or another until 1910 when he was assigned to the company's Boston office. But the power of the Pacific to attract him remained unabated and he returned to the more equable climate of Southern California there to contemplate the passing show in leisure which he so well deserved.

✦

L. W. Miles

Lowell W. Miles, employment manager for the Interstate Public Service Company, Indiana Service Corporation and other co-ordinated utilities in Indiana under Insull management, died on Nov. 11.

Mr. Miles was born in Elwood, Ind., in 1898. After being graduated from Indiana University in 1922, he was associated in appraisal work for several years with Robert M. Feustel, a consulting engineer, now chief operating executive of the Insull companies in Indiana. He joined the Indiana Service Corporation at Fort Wayne in 1925 as manager of motor coach operations. In 1926 he was made statistician of the company and in August, 1929, he became employment manager of the co-ordinated companies at Indianapolis.

✦

H. R. Bowie

Hanson R. Bowie, auditor of the Penn-Ohio Transportation System, assistant general auditor of Ohio Edison and auditor of Pennsylvania Power Company, died recently.

Mr. Bowie was born in Uniontown, Pa., July 19, 1881. He went to Youngstown as assistant auditor of The Pennsylvania-Ohio Power & Light Company and associate companies, and was appointed auditor in April, 1928, on the resignation of F. E. Wilkin.

Throughout the period of the war, Mr. Bowie was in the cost accounting division of the Army Ordnance depart-

Digitized by Google

ment, being stationed at the Winchester Repeating Arms Company, New Haven, Conn., for the greater part of his service. Prior to the war he had been employed in the accounting departments of the Pacific Light & Power Company and the Southern California Edison Company. He was graduated from the Southwestern University of Southern California in accounting and commercial law.

✦

R. F. Clinch

R. Floyd Clinch, vice-president and a director of the Chicago, North Shore & Milwaukee Railroad and of the Chicago, Aurora & Elgin Railroad and a director of the Chicago Rapid Transit Company, died suddenly on Nov. 7 of heart disease.

In 1889 Mr. Clinch and the late John Crear organized the Crear-Clinch Coal Company, of which he was president at the time of his death. In addition to his electric railway affiliations, he was a director of the Central Trust Company, of Chicago; president of the Michigan Transit Company; of the Traverse City State Bank of Traverse City, Mich., and of the Hannah & Lay Mercantile Company; and receiver for the Chicago Auditorium Association.

Mr. Clinch was born in Georgia 65 years ago. He was educated in private schools in Georgia and later attended a military academy in Pennsylvania. He went to Chicago in 1883 and became associated with the Joliet Steel Company.

✦

T. Coleman du Pont

T. Coleman du Pont, former United States Senator from Delaware, banker, insurance man, powder manufacturer, coal miner, steel man, and street railway executive, died at Wilmington, Del., on Nov. 11. Mr. du Pont was a native of Louisville, where his family established some of the first street railways in Kentucky. Mr. du Pont was educated in Louisville schools, and at the Massachusetts Institute of Technology. His first business experience was in his father's coal mines at Central City, Ky., for the Central Coal & Iron Company, of which he later became president. In 1894 he went to Johnstown, Pa., and entered street railway work. At one time he was president of the railway in Johnstown, Pa., and controlled others in New York and New Jersey. Years ago he was instrumental in formation of the du Pont Manual Training High School in Louisville through a large donation.

✦

E. P. Charlton

E. P. Charlton, one of the original trustees of the Eastern Massachusetts Street Railway, to which post he was named by the Governor of Massachusetts in 1919, died on Nov. 20. Mr. Charlton was appointed to the board from Fall River, of which place he had long been a resident. There he served in banking, as a merchant and as a mill owner. It was his varied experience and his general appreciation of the needs of the territory served by the railway that led to his being named a railway trustee. He also served as a director of the New Haven Railroad. To industry he was, perhaps, best known as a vice-president of the F. W. Woolworth Company, with which the Charlton stores were combined in 1912. During the World War he served on the War Industries Board, at Washington, performing notable service. He later entered the War Department to aid in the purchase of supplies. He was a liberal contributor to charity.

Jacob Fishback

Jacob Fishback, 83 years old, who worked his way from a job as driver of a mule-drawn street car at Louisville, Ky., in 1869, to the position of assistant superintendent of transportation of the Louisville Railway, died on Nov. 10. He had been assistant superintendent since 1890.

Born in Somerset, Ky., Mr. Fishback received his education in the schools of Russell, Pulaski, Garrard, Boyle and Fayette Counties. He was early thrown on his own resources and worked in Lexington, Ky., for some years as a clerk. In 1869 he entered the employ of the Central Passenger Railroad in Louisville as a mule car driver. In 1872 he was made foreman of the carhouse and stables at Fifth and Oak Streets, and six years later was promoted to foreman of the railroad's carhouse at Eighteenth and Walnut Streets.

After the merger of the then existing railways of Louisville into the Louisville Railway Colonel Fishback was made assistant superintendent in charge of the car building and repair shops at Eighteenth and Walnut Streets. He was also made assistant superintendent of transportation at the same time.

✦

David W. Hennessey, general manager of the Ohio River Railway & Power Company, Pomeroy, Ohio, died at his home in Pomeroy on Nov. 18. He was 46 years of age.

Arthur W. Thompson

A. W. Thompson

Arthur W. Thompson, former president of the United Gas Improvement Company and of the Pittsburgh Railways, died on Nov. 9. His service with the United Gas Improvement Company extended from Sept. 1, 1926, until January, 1929, when he retired owing to impaired health. After an extended trip abroad he established offices in Philadelphia as a consultant.

Following long and prominent serving in the steam railroad field, Mr. Thompson entered utility work where he became well known as a sturdy force in Pittsburgh after the war, serving as president of the Philadelphia Company in that city. It was he as his associates in the railway who convinced the many communities served by that company they could furnish all classes of common carrier transportation service. Not only that but they secured a new and favorable franchise and established a point of view on the part of the public toward the company that was a most notable achievement for co-ordinated transportation. It was these accomplishments among others which made it possible for the company to come within the requirements laid down by the Coffin foundation for that contest and to be returned the winner in 1925.

For more than fourteen years before that, the Pittsburgh Railways had been at odds with the city, during which seven separate and distinct reports had been presented. They involved more than $700,000, spent by the city, the Public Service Commission and the company to ascertain a valuation. All of this work was followed by a six-year receivership. Despite their heroic work, the receivers were unable to rehabilitate the company financially and were unable to finance the purchase of equipment or to improve the property except out of earnings. Finally the Pittsburgh Railways was turned back to the owners on petition of the city and the owners, to permit a trial operation of the new agreement. It was out of this chaos that Mr. Thompson and his associates lifted the Pittsburgh Railways to heights of accomplishments in the way of physical improvement, financial betterment and public relations which won for it the highest awards within the power of the industry to bestow. And at the convention of the association in 1925, Mr. Thompson, in accepting the award, graciously bestowed the credit for the accomplishments on his associates.

To those in the electric railway industry Mr. Thompson was best known by his work at Pittsburgh. To that work he brought the experience of a career which began as a rodman while he was still in college and culminated with him a vice-president of the B. & O. Railroad. Following his graduation from the civil engineering department at Allegheny College in 1897 he started as a draftsman with Wilkins & Davison at Pittsburgh and there served the hard school of railroad apprenticeship, being drafted from one important post to another until finally he became federal manager of several railroads during the war-time period. In his last post with the Baltimore & Ohio System he was in charge of operations, traffic, engineering and commercial developments. As chief engineer he supervised the expenditure of more than $1,000,000 per month in construction work over a long period. He had charge of the construction of the 6-mile $6,000,000 Magnolia cut-off, and while chief engineer of maintenance of way, he set a world record in the removal and replacement of bridges under traffic. These facts merely hint at the record of the man's accomplishments. They do not tell the full story. Mr. Thompson was born in Erie, Pa., on May 8, 1875.

Last eight Brill trolley buses placed in service have a reduced length but retain characteristic design and construction

Latest Brill Trolley Buses Delivered to Chicago

Since the Chicago Surface Lines started its program of trolley bus installations, 21 Brill trolley buses have been delivered. The last eight to be placed in service represent the latest 40-passenger type, which are shorter than their predecessors. The all-metal body was designed to combine profitable light weight with economical sturdiness. With the higher rates of acceleration, free running speed and consequently increased braking efficiency essential to trolley bus operation, the strain upon the construction, particularly in the roof and roof supports, is naturally greater. Much consideration has been given to the design of these parts and provision made to take care of it, resulting in the adoption of wide, substantial corner-pier construction.

In the underframe chassis, framing of ample strength and flexibility is furnished, while channel side and cross members provide adequate attachment for semi-elliptic springs, motor framing and other necessary equipment. Steel angle side sills, wood filled U-shaped pressed-steel side posts and carlines, side sheathing below the windows of No. 16 copper bearing steel securely riveted to adjacent members, No. 16 gauge pressed-steel letterboards and No. 18 gauge steel wheelhousings are the principal members of the body structure.

In the body of the Brill trolley bus streamline design is followed, placing emphasis upon attractive appearance in the interest of public appeal. Eight Brill exhaust ventilators, an adequately large ventilator under the metal sun visor over the windshield and two louvre type ventilators over the rear window supplement the raisable sash to the left of the operator. With the exception of windshield, adjoining wing sash, and that above the rear cross seat which are stationary, the windows are fitted with double sash, framed in tubular brass, the lower portion of which can be raised. The individual upper sash are stationary.

Inside the trolley bus, eleven Brill No. 306 semi-bucket type cove-back transverse seats with deep spring leather upholstered cushions, are provided together with longitudinal seats over wheelhousings and full width rear cross seat which also has semi-bucket cover type backs. For the operator, a Brill De Luxe 1001 seat, leather-upholstered, is adjustable both longitudinally and vertically to obtain maximum comfort for the operator. The Haskelite ceiling and inside finish, including side lining of plywood, are painted in harmony with the seat upholstery. Double coil cross-seat type electric heaters and cab heater located near the operator are also provided.

Double stream two-part folding doors for passenger entrance and exit at forward right-hand body corner are pneumatically controlled by the operator. Single stream double-folding exit doors on the right at rear are controlled by step treadle.

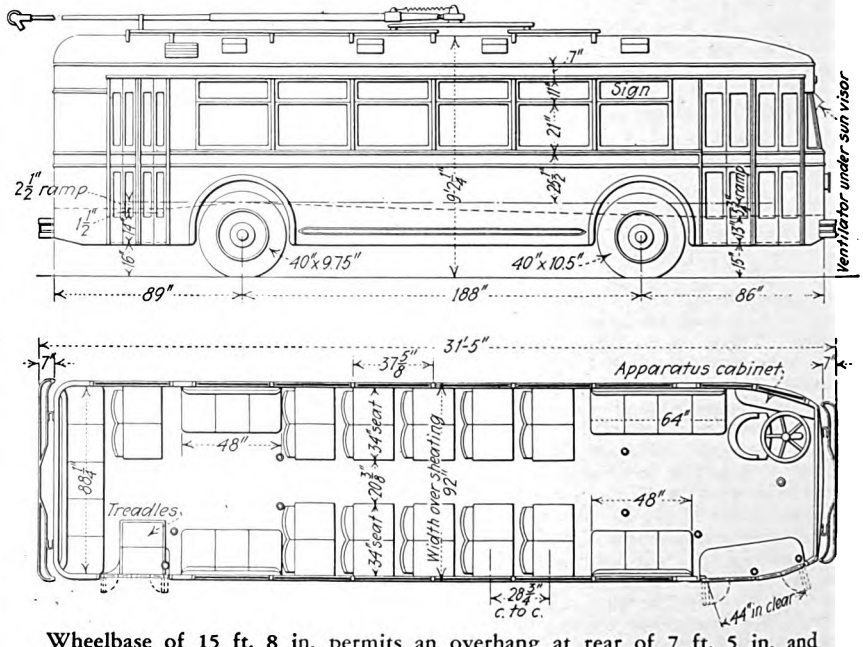
The rear axle of the Brill trolley bus is the standard Timken-Detroit dual worm Type No. 6536-W arranged for two motor drive, and the front axle is the Timken-Detroit one-piece forged axle No. 1669-W. Consequently the yellow pine floor, level at front platform, has a ramp back to wheelhousing from which point there is a 2-in. ramp downward to the rear.

A wheelbase of 15 ft. 8 in. is arranged to permit an overhang at rear of 7 ft. 5 in. and 7 ft. 2 in. at front. With the mounting of practically all equipment toward the rear and the long overhang at this point a load distribution of 40 per cent at front and 60 per cent at rear is obtained. The tire equipment consists of 40x9.75 dual tires at rear, and 40x10.5 single at front recommended by tire manufacturers for this type and weight of vehicle.

In the last eight trolley buses furnished to Chicago, the electrical equipment was furnished by the Westinghouse Electric & Manufacturing Company. Motors are two 50-hp., 600-volt Westinghouse 1426-CT-6 type. Control is the single-end automotive accelerating type, foot-pedal operation, with remote type control. The contactor box, reverser and other such equipment are housed in a noise-insulated compartment under the rear transverse seat. Access to this compartment is from the outside through an especially designed hinged door.

Completely equipped ready for operation the latest type Brill 40-passenger trolley bus furnished Chicago weighed 17,640 lb. and were equipped as follows:

Air brakes	Westinghouse DH-10
Axles	Timken-Detroit
Brakes	Timken four-wheel drum type
Bumpers	A. C. Co., spring steel
Buzzers	Consolidated Car Heating Co.
Car trimmings	Statuary bronze
Conduits and junction boxes	Flexible
Control	Westinghouse Type VA, single-end.
Registers	International R-10
Sash fixtures	Adams & Westlake, brass sash
Seats	Brill No. 306 semi-bucket type
Seating material	Leather
Springs	Detroit Steel Products Co.
Step treads	Kass safety
Tail lights	American Car Co.
Trolley retrievers	Ohio Brass Company
Destination signs	Hunter illuminated
Door operating mechanism	National Pneumatic Company
Hand brakes	Propeller shaft type
Heaters	Consolidated Car Heating Company
Headlights	Ohio Brass Company
Headlining	⅛-in. Haskelite
Motors	Two Westinghouse Type 1426-CT-6
Paint	Duco
Trolley base	Ohio Brass Company
Ventilators	Railway Utility Company
Wheels	Budd ventilated type
Speedometer	Stewart-Warner
Steering gear	Ross
Horn	Pneuphonic
Thermostat	Consolidated Car Heating Company



Wheelbase of 15 ft. 8 in. permits an overhang at rear of 7 ft. 5 in. and 7 ft. 2 in. at front

Extensive Car Replacements Needed

Recovery of the car building industry from the doldrums which have enveloped it for the past five years is inevitable, according to George Frey, vice-president of the J. G. Brill Company. Mr. Frey is not prepared to say when the recovery will begin, but he believes that the rail ways cannot delay making replacements much longer.

According to an interview with him in the *Philadelphia Record* he said that approximately 50 per cent of the street cars now in operation in the United States are hopelessly antiquated and many of them were built to conform to the needs and transportation theories of 25 years ago.

"Replacement of this out-of-date equipment," said Mr. Frey, "is imperative for railroads and street railway companies in order for them to compete with motor coaches and the private automobile. But they are deferring the placing of orders under a program of economy forced upon them by unfavorable circumstances. They cannot wait much longer." He listed high taxation, paving charges and politics among the circumstances holding back developments, all of which discourage financing projects.

Up to five years ago the 30-acre Brill plant in Philadelphia, according to Mr. Frey, produced an average of 3,000 cars a year and operated under the slogan of a car an hour. Since 1925, however, the output has dropped to an average of only 500 cars annually. The present industrial depression, he added, had little effect on street car building and had resulted in scarcely any curtailment on the Brill plant personnel.

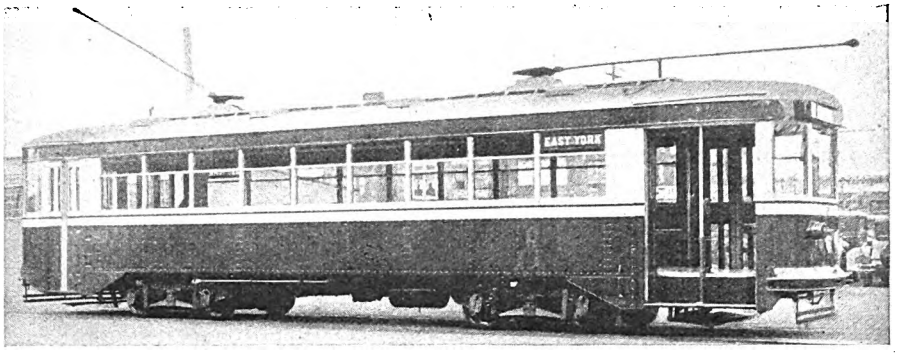
Mr. Frey believes that the electric trolley car operating on tracks is in no danger of becoming extinct despite the challenge of motor coaches, trolley buses and other forms of transportation. But the trolley of tomorrow will scarcely be recognized as a descendant of the old type car, bare and comfortless, still in use in many cities.

Luxury will be the keynote of the trolley of the future as it even now is beginning to be. Luxurious fittings, deep cushioned leather seats, designed for comfort and elegance will be enjoyed by the man riding to work. There will be linoleum on the floor and decorative effects throughout. Observation platforms have been planned on interurban lines. The death knell of the "Toonerville trolley" transportation has been definitely sounded.

Final Lot of Steel Motor Cars Delivered to L.I.R.R.

Thirteen new steel motor cars, the last of the final installment of 85, have been delivered to and placed in service by the Long Island Railroad. This increase in passenger equipment has been obtained at an approximate cost of $3,000,000. It has also been necessary to appropriate a further sum of approximately $1,500,000 for the erection of nine substations and the extension of transmission lines, in order to take care of the power requirements of this additional rolling stock.

The new equipment includes roller bearing trucks, automatic door and train control, improved interior lighting arrangement, automatic ventilators, higher powered headlights and windshield wipers on motorman's cab window. The Long Island Railroad now has a total of 1,438 passenger cars, all of steel construction.



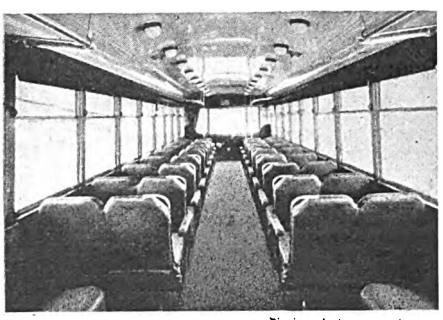
New one-man car recently placed in service by the York Railways

York Railways Accept Delivery of Three New Cars

York Railways, York, Pa., has recently placed in service three one-man, city type cars delivered by the J. G. Brill Company. The cars have a seating capacity of 50 passengers and are equipped with folding doors at the ends.

Detailed specifications are as follows:

Name of railway	York Railways, York, Pa.
Number of units	3
Type of unit	One-man, motor, passenger, city, double end, double truck
Number of seats	50
Builder of car body	J. G. Brill Co., Philadelphia, Pa.
Date of order	5/27/30
Date of delivery	10/27/30
Weights: Car body	17,350 lb.
Trucks	13,550 lb.
Equipment	2,700 lb.
Total	33,600 lb.
Bolster centers	19 ft. 10 in.
Length over-all	43 ft. 3 in.
Length over body posts	29 ft. 10 in.
Truck wheelbase	4 ft. 10 in.
Width over-all	8 ft. 5½ in.
Height, rail to trolley base	10 ft. 5 7/8 in.
Body	All steel
Roof	Arch
Doors	End
Air brakes	General Electric straight
Armature bearings	Plain
Axles	ASTM—A-20-27 annealed
Car signal system	Faraday
Compressors	General Electric Co. CP-27-B
Conduit	Flexible
Control	Type K
Couplers	Portable bar
Curtain fixtures	XL-80
Curtain material	Pantasote No. 86, Green "K" Morocco
Destination signs	Keystone
Door mechanism	National Pneumatic Co.
Doors	Folding
Energy saving device	Economy watt hour meter
Finish	Keeler & Long
Floor covering	Armstrong linoleum
Gears and pinions	Tool Steel Gear & Pinion Co.
Glass	Plate, upper doors D. A.; lower doors, clear wire
Hand brakes	Peacock staffless
Heaters	Consolidated
Headlights	Electric Service Supplies Co. FH-916
Headlining	Agasote
Interior trim	Bronze, statuary finish
Journal bearings	Plain
Journal boxes	Brill semi-steel
Lamp fixtures	Electric Service Supplies Co.
Motors	Four GE-264-F, inside hung
Painting scheme	Orange, cream and maroon
Registers	International R-12 and R-8
Roof material	¼" tongue-and-grooved, poplar
Safety car devices	LB-4 control
Sash fixtures	O. M. Edwards brass
Seats	Brill 201-E
Seat spacing	31 in.
Slack adjusters	Brill mechanical
Steps	Stationary
Step treads	Kass
Trolley retrievers	Earll standard
Trolley base	US-20
Trolley wheels	General Electric Co.
Trucks	Brill 84-E-1-X
Ventilators	Brill square type exhaust
Wheels	Davis cast steel, diameter 26 in.
Wheelguards	H-B



Interior seating arrangement for 50-passenger capacity

English Railway Places Large Order for Electrical Equipment

Orders amounting to nearly £500,000 have been placed by the Southern Railway of England with two British firms for the electrical equipment of trains to be operated on the extension of the electrified system to Reigate, Brighton and Worthing and also for such additional trains to be provided to meet increasing passenger traffic in the London suburban areas. The orders were placed with the Metropolitan-Vickers Electrical Company, and the British Thomson-Houston Company. Electrical equipment has been ordered for 23 six-car and three five-car motor units for the trains on the Brighton line; 40 four-car motor units for the trains on the semi-fast system to Reigate, Brighton and Worthing, and twelve three-car motor units and six two-car trailer units for the additional rolling stock on suburban service. The car bodies will be built in the work shops of the Southern Railway.

30,000,000 Tons of Scrap used by Steel and Iron Industry

According to the first survey ever made of the consumption of scrap iron and steel, nearly 30,000,000 gross tons were used in 1929 in the iron and steel industry, announces Benjamin Schwartz, director general of the Institute of Scrap Iron & Steel, Inc. Of this amount about 5/6 was converted into steel ingots; the iron industry used the rest. The survey reveals also that the trend of the steel industry is toward processes that require a large scrap tonnage, according to Mr. Schwartz. At the present time the average consumption of companies that do not employ the Bessemer process is 55 per cent scrap and 45 per cent pig iron.

Eccles & Davies Machinery Company, Inc., Los Angeles, Cal., have been appointed agents for the Hollup Corporation, Chicago, Ill., manufacturers of Hollup welders and Hollup welding rods for all purposes. Stocks will be moved from the East in carload lots to California for the purpose of giving patrons the benefit of lowest possible prices.

Louisiana Power & Light Company, Algiers, La., five White Model 165A.

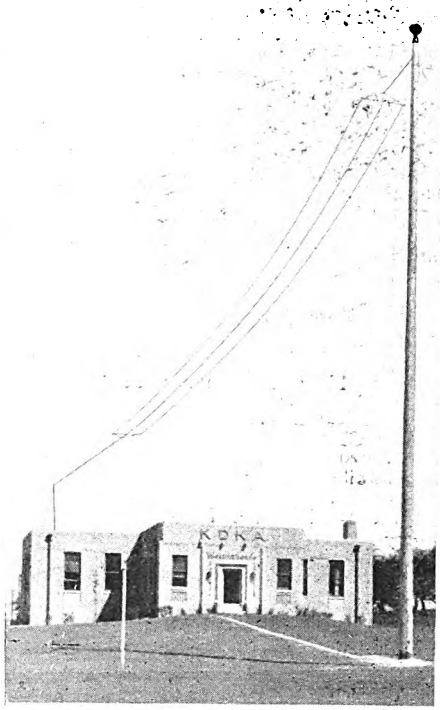
West Penn Electric Company, Pittsburgh, Pa., one White Model 54.

KDKA Celebrates Tenth Anniversary

With a special anniversary program at a dinner of the Pittsburgh Chamber of Commerce attended by many radio notables and leaders of industry, the tenth anniversary of broadcasting by Westinghouse radio station KDKA, pioneer broadcasting station, was observed recently. The anniversary program was broadcast over both KDKA and its short wave station W8XK.

Since the election of Warren G. Harding as president of the United States was broadcast Tuesday night, Nov. 2, 1920, the pioneer station of the world has not missed a single day of broadcasting. Since that first prescheduled program proved so successful, the radio industry has set a new record for progress and development.

From the modest experimental stations 2WE and 2WM, one of which was at the home of Dr. Frank Conrad, who broadcast entertainment programs each Saturday night, Westinghouse has kept pace with the remarkable progress of radio broadcasting by the construction of the new 400,000-watt transmitter at Saxonburg. This giant station required the solution of many engineering problems before it was ready to broadcast programs from the William Penn Hotel studios of KDKA, 30 miles away.



The site of the KDKA station at Saxonburg occupies 130 acres

Electric Railway Material Prices—December 1, 1930

Metals—New York

Copper, electrolytic, delivered, cents per lb.	11.00
Lead, cents per lb.	5.10
Nickel, ingot, cents per lb.	35.00
Zinc, cents per lb.	4.11
Tin, Straits, cents per lb.	26.14
Aluminum, 98 to 99 per cent, cents per lb.	22.90
Babbitt metal, warehouse, cents per lb.:	
Commercial grade	35.00
General service	30.00

Bituminous Coal

Pittsburgh mine run, net ton	$1.40
Central, Ill., screenings	0.70
Kansas screenings, Kansas City	1.50
Big Seam, Ala., mine run	1.50
Smokeless mine run, Chicago	2.05

Track Materials—Pittsburgh

Standard steel rails, gross ton	$43.00
Track spikes, $\frac{5}{8}$-in. and larger, per 100 lb.	2.80
Tie plates, cents per 100 lb.	2.075
Angle bars, cents per 100 lb.	2.75
Track bolts, per 100 lb.	3.90
Ties, white oak, Chicago, 6 in. x 8 in. x 8 ft.	1.35

Hardware—Pittsburgh

Wire nails, per keg	$1.95
Sheet iron (24 gage), cents per lb.	2.35
Sheet iron, galvanized (24 gage), cents per lb.	2.95
Auto body sheets (20 gage), cents per lb.	3.40

Waste—New York

Waste, wool, cents per lb.	12.00 to 15.00
Waste, cotton (100 lb. bale), cents per lb.:	
White	9.00 to 13.00
Colored	5.00 to 7.00

Paint Materials—New York

Linseed oil (5 bbl. lots), cents per lb.	10.00
White lead in oil (100 lb. keg), cents per lb.	13.75
Turpentine (bbl. lots), per gal.	0.48
Putty, 100 lb. tins, cents per lb.	5.50

Wire—New York

Bare copper wire, cents per lb	13.25
Rubber-covered wire, No. 14, per 1,000 ft.	5.65
Weatherproof wire base, cents per lb.	14.6

Paving Materials

Paving stone, granite, 5 in., f.o.b.: New York—Grade 1, per thousand	$150.00
Wood block paving 3½, 16 lb. treatment, N. Y., per sq.yd., f.o.b.	2.50
Paving brick 3½x8½x4, N. Y., per 1,000 in. carload lots, f.o.b.	50.00
Paving brick, 3x8½x4, N. Y., per 1,000 in. carload lots, f.o.b.	45.00
Crushed stone, ¾-in., carload lots, N. Y., per cu.yd., delivered	3.40
Cement, Chicago, in carload lots, without bags, f.o.b.	1.95
Gravel, ¾-in., cu.yd., delivered New York	3.40
Sand, cu.yd., delivered New York	2.15
Asphalt (Texas), in package, N. Y., per ton	22.50

Scrap Metal—New York

Heavy copper, cents per lb.	8.50
Light copper, cents per lb.	7.75
Heavy yellow brass, cents per lb.	5.25
Zinc, old scrap, cents per lb.	2.00
Lead, heavy, cents per lb.	4.25
Mixed babbit, cents per lb.	4.50
Battery lead plates, cents per lb.	2.13

Old Material—Chicago

Steel car axles, net ton	$13.25
Cast iron car wheels, gross ton	12.00
Steel car wheels, gross ton	13.75
Leaf springs, cut apart, gross ton	13.75
Angle bars, gross ton	12.25
Brake shoes, net ton	7.50
Rails (short), gross ton	12.75
Rails (relaying), gross ton (65 lb. and heavier)	28.50
Machine shop turnings, gross ton	5.00

TRADE NOTES

J. H. Williams & Company, manufacturers of drop forgings and drop-forged tools, have just closed contracts for an addition to their plant at Buffalo, N. Y. The extension will provide an increase of approximately 30,000 sq.ft. in floor space, to be used for additional heat-treating facilities and for finishing, assembling and storage of stock products.

Maj. Walter C. Sanders, U. S. Army Reserve Corps, was ordered to active duty in Washington, D. C., from Nov. 9 to Nov. 22, where he was assigned to the office of the Assistant Secretary of War to study War Department transportation problems. Major Sanders is general manager of the railway division of the Timken Roller Bearing Company.

Southern Tractor Supply Company, 406 Geer Building, Durham, N. C., has been appointed exclusive representative for the sale of Amsco tractor links and sprockets in the District of Columbia, North Carolina, South Carolina, Eastern Tennessee, Virginia and West Virginia.

Okonite Company announces the appointment of J. E. Harrall as sales representative to the light and power industry in the district which centers around Philadelphia. Mr. Harrall was formerly district sales manager of Safety Cable Company, division of General Cable Corporation with headquarters in Philadelphia. W. R. Van Steenburgh has been appointed manager of the light and power department of the New York office territory. Mr. Van Steenburgh will direct sales and engineering activities in New York, New Jersey, Pennsylvania, Delaware, Maryland, West Virginia and the District of Columbia.

Westinghouse Completes New Subway Order

Final shipment has just been made by the Westinghouse Electric & Manufacturing Company on the largest contract for subway control ever awarded. This order included 300 sets of controls for the Eighth Avenue subway in New York. Shipment was made to the Board of Transportation of New York City. Electrical equipment for the contract also includes 610 motors of 190 hp. each. The last of these power units will have been shipped by Westinghouse by the end of the year.

Old Generator Finds a Haven in the Franklin Institute

After many years of satisfactory and continuous service in various locations of the Philadelphia Rapid Transit Company, an electric generator has come to the end of the trail in the Museum of Electricity of the Franklin Institute, Philadelphia. The machine was sought by the Ford Museum in Dearborn, but there was a natural wish to keep the generator in Philadelphia. The machine was manufactured by the General Electric Company, and shipped to the World's Fair in Chicago in 1893, where it was acquired by the P.R.T. The generator was first used as a light generator in the Sutherland Avenue Power Station, the first electric railway generating station in Philadelphia.

TIMKEN BEARING EQUIPPED

Timken-Equipped Cars Handle Peak Loads with Peak Profits

VOLUME of traffic doesn't mean anything unless handled at a cost that represents maximum profit per car.

The greater the loads, the greater is the necessity for Timken friction-elimination, power conservation and lubricant saving.

Electric car companies have found in modern Timken-equipped cars, the secret of profitable operation under modern competitive conditions.

It isn't only a matter of reduced car mile running costs. Maintenance costs are also slashed to the bone by Timken capacity to carry all loads—radial, thrust or both at once—thus increasing endurance and extending car life.

Every modern anti-friction necessity is contained in the exclusive combination of Timken tapered construction, Timken positively aligned rolls and Timken-made steel. The Timken Roller Bearing Company, Canton, Ohio.

14 YEARS' SUCCESSFUL OPERATION

----the basis of repeat orders

IN 1916 and 1917, the Salt Lake and Utah Railroad placed in service its first two Baldwin-Westinghouse locomotives. In 1920, three similar standard Baldwin-Westinghouse locomotives were added to its rolling stock. And now, after many years of successful operation, another has been added, bringing the total to six—all standard Baldwin-Westinghouse locomotives, operating in regular revenue service.

Of particular interest about the latest locomotive is the "clear view" feature. All equipment within the cab is kept below the direct line of vision of the operator thus affording him a perfect view—a necessary requisite of safety.

Baldwin-Westinghouse locomotives all over the country are attracting new business by furnishing reliable and speedy freight movement. Write either company for full particulars about standard Baldwin-Westinghouse electric locomotives.

A standard Baldwin-Westinghouse Locomotive recently delivered to the Salt Lake & Utah Railroad.

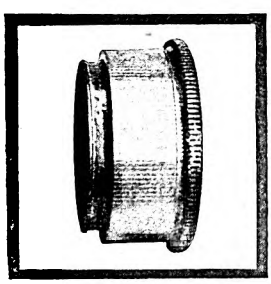
QUANTITY *production* makes QUALITY *practical*

PRESERVE

the thoroughbred strain *with Westinghouse Renewal Parts . . .*

WHEN you chose Westinghouse equipment you picked a thoroughbred. When you make replacements with renewal parts manufactured outside the Westinghouse walls you are weakening the thoroughbred strain. Regardless of the quality of the material and the careful design that go into the construction of the renewal part, if the work is done without the original drawings, specifications, and tools, a perfect reproduction can hardly be expected. The piece may *work* but, after all, almost any horse can run—it took generations of careful breeding to produce a Man-o-war.



The Westinghouse Renewal Parts Plant at Homewood, Pa., is under the direction of an engineering group of specialists whose facilities are devoted to the study and manufacture of renewal parts.

Let the same logical thinking that led you to buy superior equipment, be your guide in making this important decision, when purchasing your renewal parts.

Service, prompt and efficient, by a coast-to-coast chain of well-equipped shops

Why not order *all* car equipment from *one* dependable source?

Keystone electric railway car equipment is installed on the finest of modern cars. A representative car is Keystone-equipped throughout, from trolley wheel to the Golden Glow Headlight on the front end. Keystone specialties include gear-cases, trolley poles and cords, trolley catchers, lighting fixtures, signal systems, alarms, fare registers, etc., etc.

The best way to order is from our *687-page* catalog of car equipment. We'll be glad to send copies to buyers and executives. *Ask for catalog No. 7.*

A great deal of effort was put behind the publication of Catalog No. 7, in order that you would have first-hand information on all equipment and parts. Since the publication of this catalog a number of supplementary sheets have been issued listing particularly the new interior lighting fixtures. We will be glad to send these to you upon request.

Old-time roads cannot carry new-day traffic

Digitized by Google

Yesterday's highways couldn't carry to-day's motor cars, but yesterday's rails can carry to-day's street cars.

It's much easier and cheaper to restore the youth of old rail than to rejuvenate an obsolete highway.

All that's needed is suitable modern equipment—such as the rail grinders and arc welders here displayed for your selection.

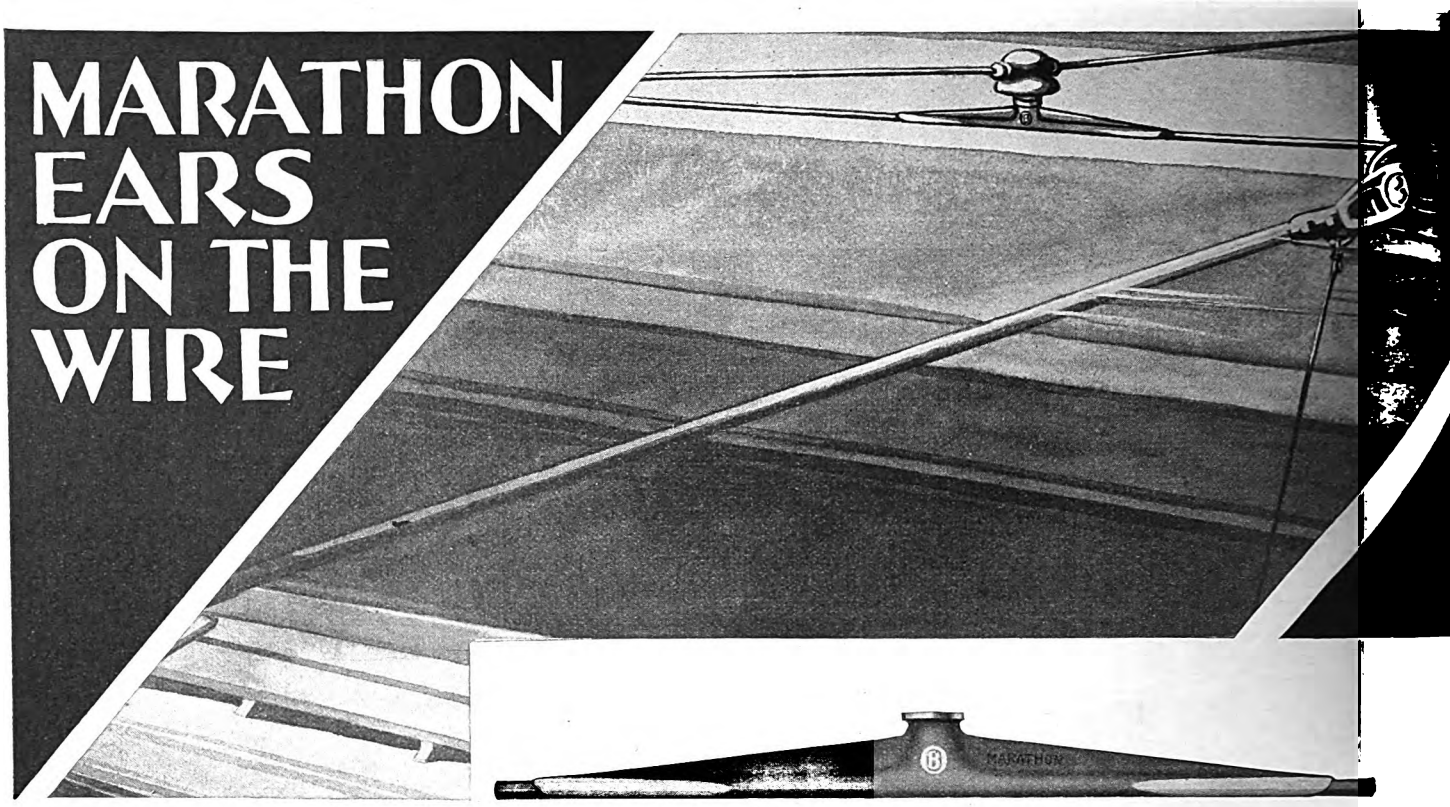
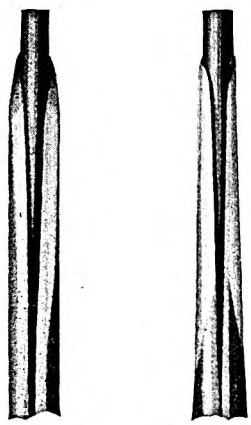
MARATHON EARS ON THE WIRE





The Old Type Ear **The *Improved* Marathon Ear**

These sections of ends tell the story. The abrupt approach and leave has given way to the taper with the result that the wheel passes smoothly and steadily across the ear without bumping, bouncing or arcing.

THE introduction of the *improved* Marathon Ear three months ago has awakened a most active interest among electric railway men. Never has O-B introduced a new product which received any greater evidence of approval—not even excepting the exceedingly popular original Marathon Ear, introduced in 1923.

One Missouri property changes from its customary brand and orders four hundred *improved* Marathons; a large property in Alabama recognizes the advantages of the tapered approach and orders one thousand *improved* Marathons; a Canadian property foresees the reduced wear on ears, wire and wheels and orders fifteen hundred *improved* Marathons; two Pennsylvania properties send in large orders based on the obvious excellence of *improved* Marathons. Concrete evidence comes from scores of properties that *improved* Marathon Ears have "taken".

An early investigation on your part might properly lead to the conclusion that *improved* Marathon Ears will likewise reduce costs on your property. Ask your O-B Salesman, or see page 44 of New Products Supplement No. 4 to O-B Catalog No. 20 for complete description and ordering information.

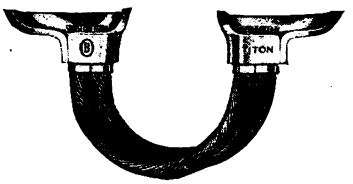
O-B BONDS ON THE RAIL

AMONG the most important of the recent rehabilitation programs to be completed is that of the Windsor, Essex & Lake Shore Electric Railway. This property extends from Windsor to Leamington, Ontario—a distance of thirty-six miles—and is operated by the Hydro Electric Power Commission of Ontario. Complete rehabilitation of track, overhead and rolling stock has been effected, with a resultant increase in operating efficiency.

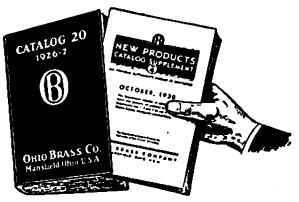
Indicative of the operator's efforts to keep operation and maintenance costs at a minimum was their selection and use of 13,000 O-B Titon Rail Bonds. This choice was made after exhaustive service tests and was influenced somewhat by the excellent performance records of Titon Bonds on many other properties.

O-B Titon Bonds are installed by copper electrode arc welding and are applied to the head of the rail with O-B Duron Welding Rod. A copper sleeve, which distributes and dampens out vibrations and adds to the life of the bond, surrounds the wire inside the terminals. The design of the terminals permits beveling of deposited metal from the rail so as to escape wheel contact. Thus is the service life of the bond materially lengthened.

O-B Titon Bonds are fully described on page 667 of O-B Catalog No. 20. Other types of O-B Bonds will be found in the same section.



The O-B Titon Bond, showing terminal construction. Note copper sleeves surrounding strand ends inside of terminal.



Twenty-four pages of New Products Supplement No. 4 to O-B Catalog No. 20 are allotted to bonds and bonding equipment. If you do not have a copy, write for one.

SITTING STILL IS PROFITABLE

Most people picture hustle and bustle when thinking of a profitable business. But the restful, still-sitting passenger certainly leads to a profitable operation for the electric railway. In your own advertising (if you are not already doing so) call the passengers' attention to the rest and ease found in your seats. And be sure to provide that comfort by installing Hale & Kilburn equipment.

STOODY MANGANESE WELDING ROD

Deposits 12 to 14% manganese steel which is clean, close grained, sufficiently hard and surprisingly tough.

Furthermore, the deposit is made with the least possible heat (from 100 to 125 amperes and 20 to 25 volts when the application is made electrically). Consequently the parent metal on which the deposit is made remains uninjured.

You Should Standardize on Stoody Manganese Welding Rod and Lengthen the Life of Your Special Track Work

Pittsburgh **Chicago** **Albany** 120 BROADWAY

Digitized by Google

IN 1930

the rail was worn out after sixteen more years under heavy city service . . .

IT TOOK courage, back in 1914, to spend good money for Thermit-welding track in which the joints were already badly worn. Thermit had not then won the recognition it now possesses. It was still generally considered an experiment in America. It is to the credit of the officials of Third Avenue Railway System of those days, that they recognized an opportunity. The rail itself was still good, but the joints were "shot." And so they decided to Thermit-weld. They took a courageous step to save money by spending money.

And what a return this investment paid! Think of street car track, in front of the General Post Office in the heart of New York City, rejuvenated by Thermit-welding in 1914 and then lasting until 1930. Many a road has laid new track since 1914 and has had to replace it already, even under lighter traffic conditions. Why? Because the joints which are the weak spots in every piece of track are often neglected.

Thermit-welding is really most economical. It eliminates the weak spots by eliminating the joints.

New track—laid with Thermit joints will last longer and cost less to maintain. Joint repairs will be practically nil.

Old track—can be saved for years of further useful life by Thermit-welding every joint. It will ride more smoothly and wear more evenly.

Now is the time to save by spending money—carefully! Let us make a survey of the rail joint situation on your property and offer a Thermit-welding maintenance plan. No obligation involved.

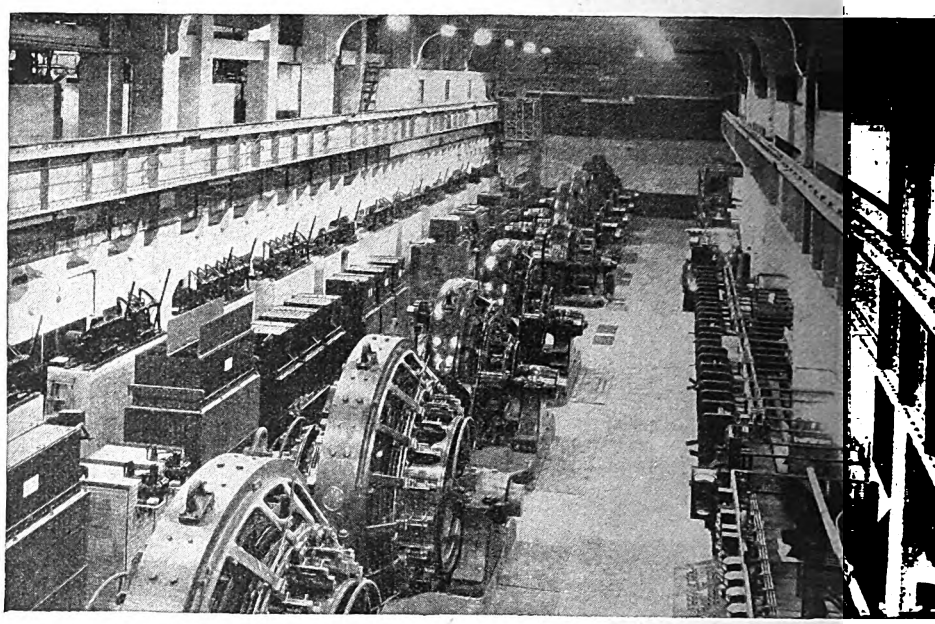
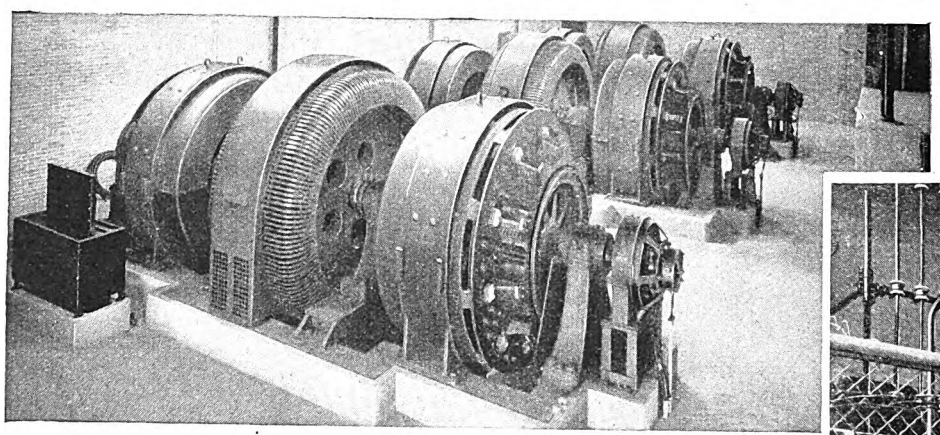
Reliable Power—

GRAND CENTRAL SUBSTATION of the New York Central Railroad is located 100 feet below the street level at Forty-third Street and Lexington Avenue. The equipment includes ten G-E synchronous converters, several being of 4,000-kw. capacity, and G-E manual switchgear



The CLEVELAND UNION TERMINAL electrification is supplied with power through two G-E equipped automatic substations. Substation No. 1 includes three 3-unit, 3,000-kw., 3,000-volt, direct-current synchronous motor-generator sets complete with automatic and supervisory switchgear



The DELAWARE, LACKAWANNA AND WESTERN railroad electrification is supplied with 3,000-volt direct current through 13 G-E mercury-arc rectifier units ranging in capacity from 1,500-kw. to 3,000-kw. The transformers and switchgear are also of General Electric manufacture.

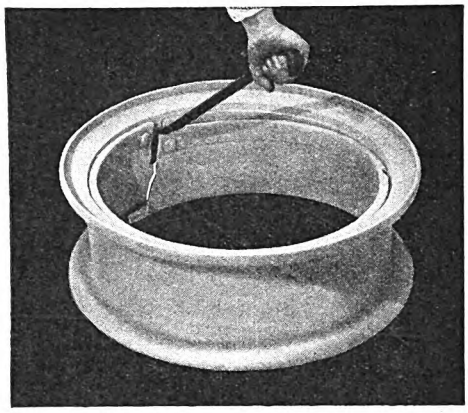
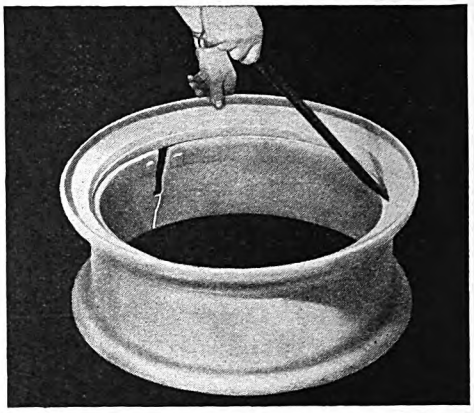
OPERATION OF K RIMS IS SIMPLICITY ITSELF!



Pry No. 1—at the joint



Pry No. 2—at the side. Rim is ready for tire

To save time and cost use K Rims *as standard fleet equipment*

Fastest rim to operate. Two pries with a bar prepare K Rims for mounting tires. When tire is mounted, rim parts are firmly locked together and will not separate — always safe on road. Open valve-stem slot for further ease in handling. K Rims are interchangeable when used for singles or duals. Construction strong and light and permits maximum ventilation for heated brake drums. They guard against premature tire failure; economical always. Standard rims for money-making trucks and buses everywhere. Specify for your fleet now.

All vehicles of Columbia Gorge Motor Coach System, Portland, Oregon, are equipped with Goodyear Bus Balloon Tires

"Traction so good, chains were rarely used"

—and it was mountain driving in winter!

"Portland—Boise—Bend—Pendleton—Yakima—Spokane—Lewiston—Salt Lake—Chicago"—these are the names on the side of this coach, and if you spot those cities on the map, you will find real mountain driving between them.

"Since this company's equipment has all been changed over to balloon tires," says a letter from Columbia Gorge Motor Coach System, "it has been noted that the mileage per tire has increased greatly with practically no delay of schedules on account of tire trouble... also, as we have gone through the worst of the winter months, we can say that these tires have very good traction on wet and slippery pavements, considering the fact that chains have only been used on our buses when road conditions were unusually bad and for only a very short time."

The tires, of course, are Goodyear Bus Balloons—the traction being provided by the famous Goodyear All-Weather Tread.

Group observing operation of electrically operated model of "Mortar-Flow" Pulsator.

Make Your Own Demonstration Of The "Mortar-Flow"* Principle On Your Own Desk!

SEVERAL operating, quarter size models of the "Mortar-Flow" Pulsator (Derail Type) are now available for a demonstration which you can make yourself in your own office to a group of your track men. On request the model, with complete instructions for its operation, will be expressed direct to your office.

Only by actually seeing the "mortar-flow" method (vibration during placement) in operation can you see the reason why it makes *all* the concrete in any type of construction effective; how, by causing the concrete to flow and bond with the steel, it fills all voids and seals the track structure against surface water—see how the labor of spreading and leveling is reduced; how hand tamping is eliminated and why a denser, more waterproof concrete is produced because excess water is brought to the top of the slab.

See why maximum results with the "mortar-flow" method (vibration during placement) are obtained with Steel Twin Ties.

You've heard about it; how widely it is approved by users—now see it operating on your own desk. There is no obligation of any kind except to return the model when you have finished with it, express collect.

IN using the "Mortar-Flow" Principle, for vibration of any type of track structure during placement of concrete to cause it to settle, flow, fill voids and bond with the structure, you are protected by U. S. Patent Nos. 1,745,744 and 1,770,154.

*The "Mortar-Flow" Principle is the vibration of the structure during concreting.

A Comfortable, Sanitary and Modern Seat!

HERE is a seat which maintenance engineers will appreciate. Its close-woven cane webbing back and cushion are easy to keep clean. The genuine leather facing on the cushion reinforces the seat at the greatest point of wear. In addition, the individual backs and deep, spring cushions are shaped to allow proper posture and leg freedom. Mechanism rails are set in and the frame of the chair is made of selected Northern hard-grained ash, further strengthened by malleable iron braces. Write to the nearest Heywood-Wakefield sales office for complete details of the 327-M Special and other popular bus and electric railway seats in our line.

If you have not received a copy of our new Bus Seat Catalogue, write for it.

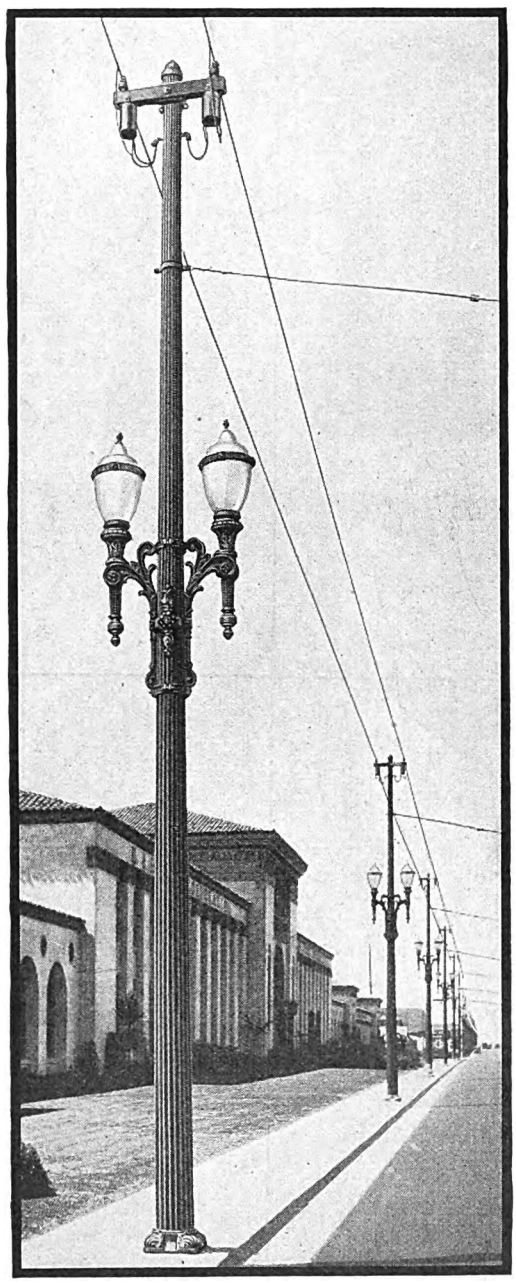
Now Berkeley Chooses Fluted Steel POLES



Berkeley, California, is noted for its beautiful thoroughfares

REPLACING other poles and individual lighting standards, Union Metal Heavy Duty Poles have transformed the appearance of San Pablo Avenue in Berkeley, California.

These 32-foot poles perform their numerous duties safely and with a minimum of attention. Slender, straight and uniform, they represent the ideal method of carrying electrical services through city streets.

In Berkeley the Union Metal Poles are equipped with twin street lighting units, cross arms, trolley span-wire supports and concealed cable-risers. In numerous other cities they are also used for a multitude of duties — often at a great saving in cost and always to the betterment of street appearance.

If you are not familiar with this advanced type of pole write for complete information.

Changing the complexion of a white elephant in Olean, N. Y.

The economical conditions affecting many of the hundreds of small inter-urban properties in America are, in many respects, identical.

Transportation men, individually and collectively, have studied and analyzed this problem repeatedly, yet it still remains one of the most discussed problems of transportation.

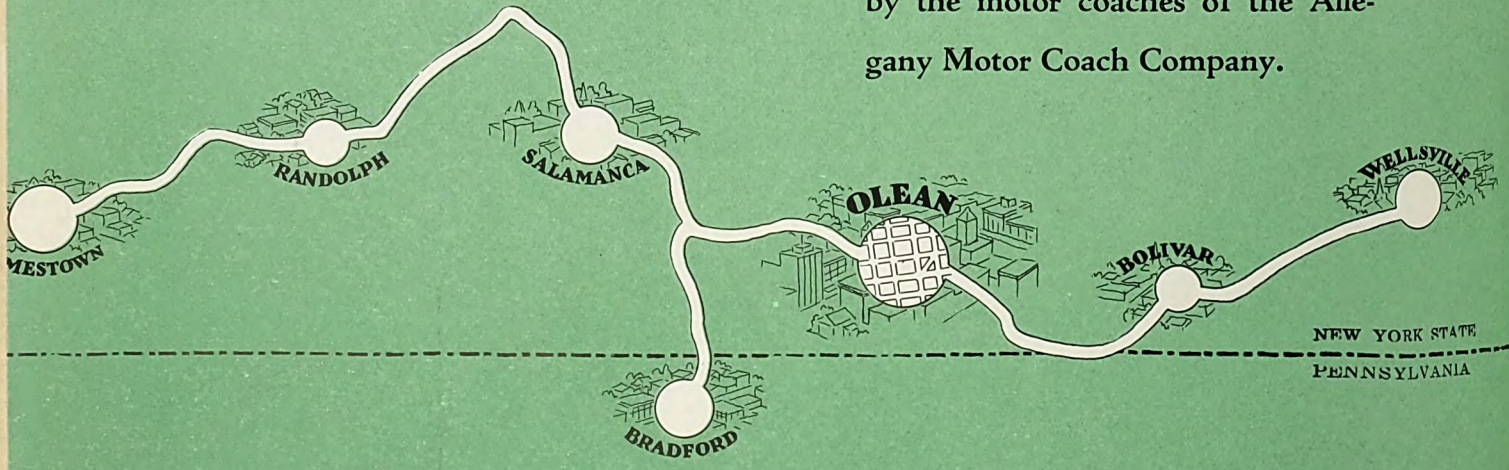
Here is another splendid example of how a small city and inter-urban operation, that had become hopelessly involved financially, went all bus — *with gratifying results.*

It can be done with

Yellow Coaches

Digitized by Google

Much the same territory previously served by the abandoned urban and interurban rail lines is now served by the motor coaches of the Allegany Motor Coach Company.



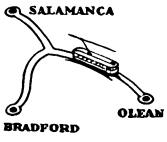
Digitized by Google

he oil boom in the Pennsylnia fields made Olean a prosperous community.

50 years ago, oil was discovered near Olean, N. Y. and the population of that busy little community had suddenly doubled — trebled. It had become a city of 10,000 people. So, its progressive citizens organized and financed a needed street railway — 1.1 miles of single track running from the railway station to the center of town! Three horse cars operating on 3 foot 6 inch track of 25 pound rail. The schedule was every 30 minutes and it took 20 minutes to cover the route.

: took twenty minutes to cover one mile of route.

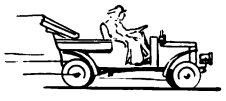
37 years ago, they were talking modernization in Olean. The transportation system had prospered. During the previous year 140,774 passengers had been carried at a 5 cent rate of fare, track mileage had been increased to 2.5 and a fourth car had been added at a cost of $314. John Forbes, President and General Manager, was receiving a salary of $1,020 a year. Drivers were paid $1.33 for a nine-hour day. Times had been good. The net annual earnings amounted to $2,661. It was an opportune time to modernize. The age of electricity had arrived. So, in 1893, electric cars were substituted for horse cars. Refinancing was easy.



Temporary conditions favored expansion and consolidation.

27 years ago they were talking consolidation in Olean. Bradford, a neighboring city just over the Pennsylvania line, also had a railway company. Interurban service between the two prosperous cities had been established as a joint operation. Then everything was consolidated. In 1906 the new company was operating 59.9 miles of single track and 27 cars, but the investment now amounted to $2,061,000. Net profits amounted to $51,000 — a 2½ per cent return.

Further expansion followed. Just 20 years ago the company had cumulated investments of $5,000,000, half of it a bonded indebtedness. Income, however, had grown to $377,802, net to $193,360 — still a 2½ per cent return.



The peak of passenger revenue was reached when the automobile arrived.

But the peak of passenger revenue and income had been reached. Automobile competition had arrived. The oil boom in Pennsylvania was over. Transportation revenues began dropping steadily year after year and despite fare increases the net finally dipped far under the amount needed to pay interest on the bonded debt, to say nothing of paying a return on the stock issued.

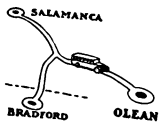
It can be done - with

Yellow

Coaches

Digitized by Google

Disgruntled stockholders became bitter in their denunciations.



The coach operation replaced the 90 mile interurban with its $5,000,000 capitalization.

The new transportation system is making a good return on its investment.

Every month in 1930 but one has been ahead of 1929 in revenue.

Service became a travesty. Slow and infrequent schedules, breakdowns and accidents became the order of the day. Wages finally represented 53 per cent of all expenses, costs per car mile amounted to 48 cents. Disgruntled stockholders became bitter in their denunciations.

Three years ago, the court ordered the property abandoned.

A more far-sighted management might have met this problem more successfully. Bond holders and stock holders might have suffered less if everyone concerned had faced the situation squarely and planned for a sound capital reorganization and revamping of the property —

For here is what actually happened.
An outsider stepped in where local talent feared to tread. Local investors and local management had fought shy of re-organization along any lines. Local transportation was in bad repute. Local capital was uninterested and afraid.

But an experienced outsider, who knew what could be accomplished with a well managed bus operation, reviewed the situation and with his own limited capital, but ample vision, started—The Allegany Motor Coach Company. And the result —

In 1928 — serving the same territory — 560,000 passengers were carried at a net earning of $11,703, or about 7.5 per cent on investment. This with only 10 coaches.

In 1929 — 600,000 passengers were carried earning $125,296 gross and a net of $12,892, or 8.2 per cent return. With the purchase of additional Yellow Coach equipment, plus operation and careful supervision, operating costs dropped from 24.2 cents per mile to 20 cents per mile.

Every month in 1930 but one has been ahead of 1929 in revenues.

Now 20 employees give adequate service to the community as against 225 at the peak of traction service. There are fewer miles operated and the service may be less frequent, but it is entirely adequate and satisfactory to the public. What is most important, the transportation service is again on a sound and profitable basis.

Faith in motor coach transportation and in Yellow Coach equipment enabled The Allegany Motor Coach Company to carry on from where the trolley had left off and converted a white elephant into a profitable business.

New Sales and Service Facilities for GREDAG
REG U. S. PAT OFF

• LUBRICANTS

ON November 1, 1930, the sales and service facilities for Gredag Lubricants, well known and long established products of the Acheson Graphite Corporation—a Unit of Union Carbide and Carbon Corporation—were greatly extended.

Gredag Lubricants are now being sold and distributed by the Carbon Sales Division of National Carbon Company, Inc.,—a technical organization which for many years has been in constant contact with industrial plants and distributors of industrial products.

The addition of Gredag Lubricants to the products of the Carbon Sales Division will bring into the lubrication field a force of competent sales engineers familiar with industrial problems. It will also add to the previous facilities five conveniently located Branch Sales Offices and Service Plants.

Please address your inquiries and orders for Gredag Lubricants to the nearest Branch Office of the Carbon Sales Division.

Is this Coincidence?

All three winners in a national speed contest for rapid transit lines use car oils made by Standard Oil Company (Indiana)

We are not trying to convince you that Standard Oil Company (Indiana) car oils were the chief factors in winning this contest. But we do want to register strongly the fact that all three winners, noted for the high speed maintained on scheduled runs day after day, are constant users of Standard Oil Company (Indiana) car oils.

Only with correct lubrication could these rapid transit lines maintain continuous high speed service. It is not only the ability of Standard Oil Company (Indiana) car journal oils to lubricate effectively at all speeds but likewise the savings they make possible by reducing bearing troubles, power costs, waste and babbitt metal that make them popular with electric railway officials . . . and worthy of your consideration.

These journal oils are made of especially selected lubricating stocks and are refined for this one purpose. They do not glaze or harden on the waste. This reduces oiling periods, saving labor and waste costs. They have proven to be very successful in both high speed interurban and ordinary street car service.

One of our men will be glad to discuss these oils with you . . . at your convenience.

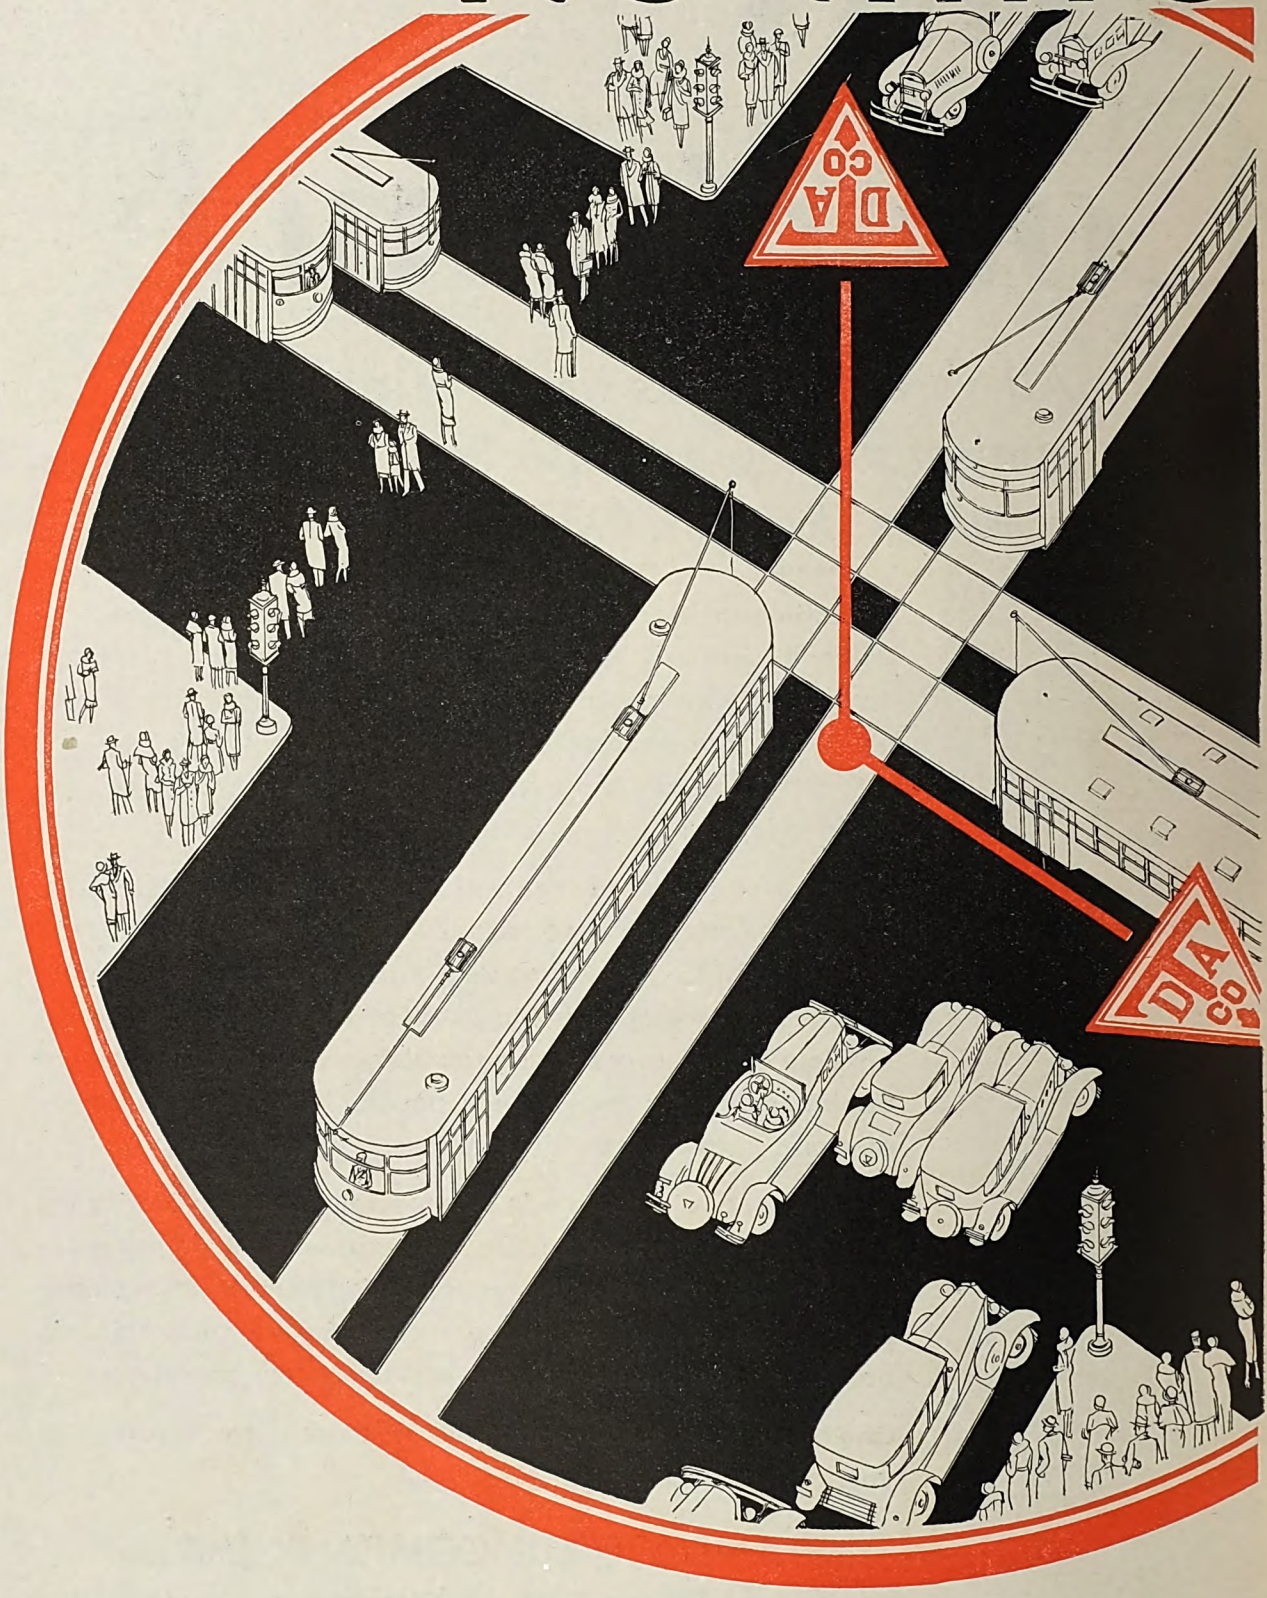
It's time



THE TIMKEN-DETROIT AXLE

Digitized by Google

to act

THERE seems to be a fundamental difference in the thinking habits which characterize the automotive and electric railway industries.

The automotive industry searches for new and better methods and equipment—one explanation for its astounding growth. It eagerly reaches out for improvements; tests them; adopts them.

The electric railway industry seems to pursue a more cautious policy. Certain men, to be sure, have shown a fine contempt for hampering tradition; but for the most part, new equipment continues to be "obsolete the day it is bought."

Timken has brought forward "something better"—the Timken Worm Drive Truck for electric railway cars.

It saves weight and power; lowers operating and maintenance costs, for track and equipment; eliminates most of the noise; and conserves man efficiency—the crews like Timken-equipped cars.

These cars appeal to car riders; once they ride in Timken worm-driven cars, their opinion of street car transportation takes a tremendous jump.

The electric railway industry needs constructive suggestions. We've made one. We've told the facts about it—been telling them for two years.

It's time for you to act.

KOOLMOTOR *perfect winter*

to Reading Transit Bus Company's large fleet . . . .

CITIES SERVICE OILS

ONCE - ALWAYS

COLD, bitter winter days cause no worry for the Reading Transit Bus Company — their buses are lubricated with KOOLMOTOR Motor Oil and KOOLMOTOR Transmission Oil— perfect cold weather lubricants. These companion products assure easy starting and easy shifting when engines are cold and — complete protection to friction surfaces and gears on the long, hard pulls that follow.

It is a tribute to the high and uniform quality of KOOLMOTOR products that they were chosen by the largest bus operator in Reading, Pa. The Reading Transit Bus Company's fleet of 18 buses travels approximately 1,000,000 miles a year, carrying about 1,500,000 passengers.

It will pay you to have a Cities Service engineer call, study your lubrication problem, and suggest ways and means of lowering your operating costs.

A new low mark in wheel costs with

DAVIS "One-Wear" STEEL WHEELS

The high maintenance costs of removing, re-turning, and replacing car wheels can be permanently and materially reduced to a minor item in car operation.

Davis «One-Wear» Steel Wheels will do it.

The reason is in their manufacture and the alloy steel used.

They are produced by triple-heat treatment, part of a carefully developed manufacturing process.

The results are great wear resistance, strength, and lightness, and

reduced operating costs per wheel mile, and

cars in service, earning revenue, not in the shop with flats and shellouts.

It is the answer to your car wheel upkeep problem.

We suggest you investigate as a matter of economy.

Business was Quiet...but the Telephone brought $22,200 in New Orders

A TRACTOR company's sales had fallen off to a marked degree. A telephone sales program to distant customers was decided upon. One result was $18,400 worth of business. Another, a $3800 order after the purchaser had refused a personal interview.

An Eastern lumber company regularly "visits" lumber yards in five states by telephone. In one month 550 carloads of lumber totaling nearly $500,000 were sold by this modern method. Toll bills averaged less than one-half of one per cent.

Business firms, large and small, are using out-of-town telephone service more than ever to increase sales . . . reduce distribution costs . . . meet competition. New markets are developed at little expense. Customers and prospects are economically contacted between salesmen's visits.

Develop your business by telephone. Best results are obtained by having a definite plan for executives and salesmen to follow. Your local Bell Telephone Business Office will gladly submit a plan to meet your needs.

Inter-city calls are cheap, definite, resultful. Typical station-to-station day rates: Pittsburgh to Indianapolis, $1.50. Boston to Atlanta, $3.50. New York to Baltimore, 90c. Philadelphia to Seattle, $8.50. Bell Telephone service is *Quick . . . Convenient . . . Universal.*

1931— What

WHAT *has happened in the industry in 1930?*

DID WE *gain or lose—and how much?*

WHAT *are our prospects for 1931?*

THESE are the questions that community transportation men are asking themselves as this unusual year nears its close. The Annual Statistical and Progress Number will not only present complete, up-to-date statistics and forecasts regarding every important activity of the field, but it will also contain timely information about such pertinent topics as the trolley bus —rapid transit—trailers—bus operation and other subjects that are claiming the attention of transportation executives.

Look for the answers

Digitized by Google

will it mean to the ELECTRIC RAILWAYS?

NEVER was there a time when executives had greater need for FACTS than in this present period of abnormal business conditions. Figures, statistics, dependable data—this kind of information, interesting always, becomes vitally important at a time like this.

In its January issue, ELECTRIC RAILWAY JOURNAL will present the facts that transportation and manufacturing executives want and need in planning for 1931.

Figures and comparisons on costs and fares—expenditures and improvements—trackage—rolling stock and every other phase of general interest will be given, all brought up to date.

ANNUAL STATISTICAL AND PROGRESS NUMBER

This year's record simply confirms past experience: in periods of dull business, the electric railway industry is among the least adversely affected. In the past half-century, the industry has weathered numerous "depressions" and gone forward again with but few scars. History promises to repeat at present. This year's revenues are off only slightly.

In addition to figures, statistics, trends and forecasts, the 1931 Statistical and Progress Number will contain a new and informative survey of Taxicab Operations by Electric Railways. This and other timely subjects will be discussed in interesting articles.

Here is a number you will want to study and keep close at hand throughout the year. If you want extra copies for others in your organization, order them early.

ADVERTISERS: Forms close December 22. This is a logical issue in which to use extra space and color.

FLY WHEEL: Balanced—Statically and Dynamically; Starting Gear—Steel ring shrunk on flywheel.

CAMSHAFT: Type—Cams and Gears Integral; Material—Drop Forged Alloy Steel; Number of Bearings—4.

VALVES: Type—Poppet; Location—Right Side of Cylinder Block; Material—Nickel Chromium Steel; Guides—Removable.

VALVE TAPPETS: Type—Mushroom; Material—Cold Drawn Carbon Steel; Head—Chilled Cast Iron Welded to Stem.

ENGINE LUBRICATION: Type—Forced Feed; Oil Pump—Gear Type; Drive—Camshaft; Pressure to Main, Connecting Rods and Camshaft Bearings and to Front End Drive; Positive Spray to Pistons, Cylinder Walls, Cams, Valve Stems and Tappets; Oil Pan—Electro Galvanized Pressed Steel; Capacity—8 Quarts; Crankcase Ventilator; Oil Filter.

CARBURETOR: Type—Air Valve Updraft; Oil Wetted Wire Mesh Air Cleaner.

FUEL PUMP: Type—Variable Stroke Diaphragm; Location—Right Rear of Crankcase; Drive—Rocker Arm off Camshaft; Filter and Sediment Trap.

ENGINE COOLING: Type—Centrifugal Pump; Thermostat; Radiator—Tubular; Shell, Chromium Plated; Fan—4 Blade; Drive—Extension of Water Pump Shaft; Heat Indicator—On Instrument Panel; Capacity of Entire System—5¾ Gallons.

BATTERY: Heavy Duty; Number of Cells—6; Number of Plates—13; Capacity—120 Ampere Hours.

DISTRIBUTOR: Heavy Duty Type; Location—Top of Cylinder Head; Drive—Vertical Shaft Gear Driven off Camshaft; Advance—Full Automatic.

GENERATOR: Location—Left Side of Engine at Front; Type—Shunt Field Voltage Regulator; Drive—2 Vee Belts Driven from Crankshaft; Mounting—Hinged for Adjustment of Driving Belts; Capacity—225 Watt; Voltage—12; Charging Rate—Hot, 12 Amps.—Cold, 16 Amps.

STARTER: Type—Positive Shift Two-Stage; Location—Left Side of Motor on Flywheel; Normal Speed of Turning Engine—100 R.P.M.

CLUTCH: Location—Unit with Power Plant; Type—Dry, Single Plate; Plate Diameter—13"; Release Mechanism—Graphite Composition; Pilot Bearing—Ball Bearing.

TRANSMISSION: Type—Selective Sliding Gear, Heavy Duty; Location—Unit with Power Plant; Number Speeds Forward—4; Number Speeds Reverse—1; Main Shaft—Ball Bearing; Countershaft—Roller Bearing; Main Shaft Pilot Bearing—Roller; Idler Shaft—Bronze Bushing (Run in Oil).

PROPELLER SHAFT: Type—Two Piece Tubular; Diameter—3"; Center Bearing—Self Aligning.

UNIVERSAL JOINTS: Type—Cross and Trunnion; Location—Transmission, Rear of Center Bearing and Rear Axle.

EMERGENCY BRAKE: Location—Rear of Center Bearing; Type—Ventilated Disc; Disc Diameter—14"; Total Braking Area—44.4 sq. in.

SERVICE BRAKES: Location—4 Wheels; Type—Hydraulic Internal Expanding; Control—Foot Pedals, Booster Actuated; Drum Diameter—Front, 16"—Rear, 16"; Lining—American Brakeblok; Width of Lining—Front, 2½"—Rear, 3½"; Braking Area—350.11 sq. in.; Drum Material—Cast Iron.

WHEELS: Type—Metal Disc, Dual Rear, 6 Mounting Studs; Rim Size—20x6 DT.

TIRES: Parlor Car—7.00/20 8-ply Dual; Street Car—7.50/20 8-ply Dual, Spacing 9".

FRONT AXLE: Type—Reverse Elliott I-Beam; Wheel Bearings—Double Tapered Roller.

REAR AXLE: Type—Full Floating; Housing—Banjo Type; Housing Material—Electric Furnace Steel Casting; Drive Gears—Spiral Bevel with Straddle Mounted Pinion; Number of Bearings Entire Axle—9.

SPRINGS: Type—Semi-Elliptic; Material—Silico Manganese High Forging Spring Steel; Number of Leaves—Front, 10—Rear, 11; Width—Front, 3"—Rear, 3½"; Length—Front, 42"—Rear, 56⅛"; Shackles—Shackles and Bushings.

FRAME: Type—Pressed Steel Channels, Double Drop; Thickness of Material—3/16"; Maximum Depth—9 13/16"; Maximum Width Flanges—3¼"; Number of Outriggers—6; Number of Cross Members—7.

STEERING: Type—Worm and Sector; Ratio—Varying Ratio, 20:1; Steering Wheel—All Metal Steel Tube, 19" Diameter.

ROAD CLEARANCE: Parlor Car—Front, 8½"; Rear, 8⅞". Street Car—Front, 8¾"; Rear, 9⅛".

TURNING RADIUS: Left 28' ¾", Right 29' 1½".

WHEEL BASE: 165 inches.

WHEEL TREAD: Front, 64¼"; Rear 66¾".

FUEL TANK: Location—Outside of Frame on Right Side; Material—Rust Proof Terne Plate; Capacity—40 Gallons.

BUMPERS: Street Car—Heavy-duty Spring Type Front; Parlor Car—Heavy-duty Spring Type Front and Rear.

CHASSIS LUBRICATION: Zerk High Pressure Grease Gun.

CONTROL: Brake and Gear Shift Levers—On Transmission Case; Horn Button—On Steering Wheel; Throttle, Choke and all Electric Control Switches on Instrument Board with Exception of High and Low Beam Headlamps, Switch for which is located on Left Side of Toe Board.

BODY SPECIFICATIONS

FRAMEWORK: Framework is of second growth thoroughly seasoned oak. Oak body pillars are mortised, glued and screwed to the roof rail and anchored by malleable brackets on each side. Brackets also rigidly join the carlines to the roof rail and pillars. All wooden parts are thoroughly treated with lead and oil and non-rusting screws are used throughout.

FRONT END: Front end is a steel structure consisting of structural steel angle corner pillars which are reinforced with gussets, riveted and welded, for maximum strength. A similar type steel framework supports the cowl and windshield.

SKIRTING: Skirting is reinforced with brackets bolted to the floor and pillars, and riveted to the angle iron extending entire length of body which rests on chassis outriggers.

SKID RAIL: Sides and rear of body are protected with heavy oak skid rail.

SIDE PANELS: Street Car—Heavy-gauge metal panels are installed in sections and the upper panels overlap those immediately below. Inner surface of panels are painted and interior of body lined with plywood. Parlor Car—Plymetal panels without interior lining.

ROOF: Haskelite, covered with wadding and thoroughly waterproofed duck.

FLOORING: 1⅛" yellow pine, tongue and groove, laid crosswise and covered with 3/16" battleship linoleum.

WINDSHIELD: One piece stationary, sloping type with heavy plate glass set in Bonderized steel sash. 2-blade windshield wiper.

WINDOWS: Raised type with satin nickel finished brass sash and equipped with anti-rattlers; fixed upper transoms. Glazed with double strength glass. Window at left of driver fitted with sliding panel for signalling purposes. Rear windows are stationary and fitted with wire reinforced glass.

STEP: All metal with non-skid safety tread.

SIGNAL SYSTEM: Bell cord.

HEATING SYSTEM: Approved circulating hot air type.

LIGHTING: Exterior—2 marker lights front and rear. Interior—Street Car, 6-21 c.p. dome lights; Parlor Car, 10-15 c.p. dome lights.

ADVERTISING RACK: Street Car: Accommodating standard advertising cards located on each side and across rear above windows.

DESTINATION SIGN: Hunter roller type accommodating two lines of destination names.

GRAB RAILS: Street Car: One stanchion at left of entrance door and one behind driver's seat. Grab rails located on ceiling at each side of aisle.

BATTERY: Enclosed in wooden box located at left of driver's seat.

TOOL BOX: Street Car: Under right front longitudinal seat. Parlor Coach: Under rear seats.

REAR VIEW MIRROR: Mounted above destination sign trap door.

GENERAL DIMENSIONS:

	Street Car	Parlor Car
Overall length of body	221½"	214½"
Overall width	94"	85¼"
Inside width	87¾"	76"
Inside height	76"	67¾"
Seat spacing	30"	31"
Seat width	34"	37"
Aisle width between seat backs	22"	
Aisle width between seat cushions	18"	15"
Width of entrance in clear	27"	28"

3 INCHES OF SMOOTH SLIDING CONTACT

This picture tells the story better than words. It's easy to see what three inches of smooth sliding contact means . . . steady power . . . no dewirements . . . no arcing . . . no burning of wire . . .

MILLER TROLLEY SHOES

Here is almost the smoothness and the perfect contact of the pantograph collector, applied in a practical, inexpensive way to the ordinary trolley. Miller Trolley Shoes fit any standard trolley pole. They have been used for years on several well-known properties. Test them—and form your own conclusions. Sample for trial sent on request of any responsible official.

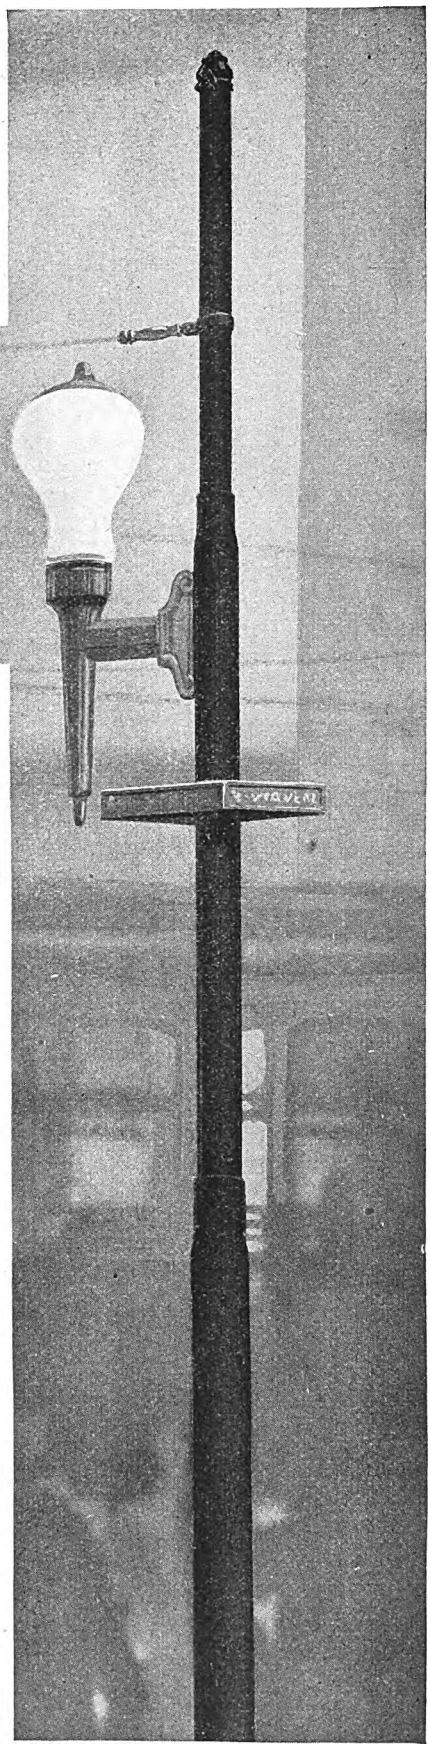
STRENGTH SAFETY *and* APPEARANCE



TUBULAR STEEL POLES

HERE is a unique combination in one pole—the three most important factors in line pole service . . . strength, safety and appearance. These three advantages offer maximum durability, adequate protection to the public, and advancement of the "city beautiful" idea—making the selection of NATIONAL Poles a most desirable investment from every standpoint.

Made by the largest manufacturer of wrought tubular products in the world, with facilities for meeting a wide range of specifications for pole construction. Ask for Bulletin No. 14, describing NATIONAL Tubular Poles, made from—

They don't have to REMEMBER

CARNEGIE STEEL TIES

after their installation

TRACK problems may properly be forgotten where Carnegie Steel Ties are used in track construction. These ties provide the foundation for a smooth, repair-free track—a track that saves wear and tear on rolling equipment and greatly enhances its comfort. In many instances where Carnegie Ties have been in service for fifteen or twenty years, rails have been taken up for renewal to find the ties in perfect condition.

Plan to include Carnegie Steel Ties in your track construction program. Their unit cost (cost per foot of track per year) is considerably less than for wood ties. They will prove an investment you will remember with satisfaction—and forget with complacency, as far as troubles are concerned.

Catalogue on request.

J-M Brake Blocks are making unusual performance records on Bus Lines . . .

MORE than 650,000 safe, quick, quiet stops is an unbelievable record for any braking material. Yet the J-M Brake Blocks shown in the photograph below made this record in 25,000 miles of service . . . and this set of blocks is still good for thousands of miles additional cost-free braking service.

This is not an isolated record of the money-saving, safe service that J-M Brake Blocks give the bus operator. More than sixty companies have tested this friction material with uniformly successful results.

J-M Brake Blocks, adaptable to many types of equipment, have been specially designed to meet the operating conditions of modern bus service.

J-M Brake Blocks, made of moulded asbestos, resist the action of oils and greases. They reduce costs by giving thousands of miles of extra service, by reducing shop time for adjustments, by increasing tire life through smooth gripping and by eliminating road delays. J-M Brake Blocks provide quiet and positive braking action. They allow higher running speeds and quicker stopping with absolute safety. They are particularly recommended for use on alloy or high-carbon drums.

From the standpoint of safety, efficiency and reduced cost of operation we ask that you test this J-M friction material. The coupon will bring you further information and performance facts.

J-M BRAKE BLOCKS
FOR BUSES AND TRUCKS

J-M Brake Blocks are recommended for use on air brakes which may be either of the diaphragm type, requiring a tank pressure of 60 lbs. or of the wheel cylinder type, requiring a pressure of from 100 to 110 lbs. They are also applicable to mechanical brakes, with vacuum boosters. These may be two wheel or four wheel brakes, the latter being used extensively on 17-21 passenger coaches. The size of the friction material in each instance runs from 1-4″ to 7-8″ thick. In the manufacture of J-M Brake Blocks, composition, density, hardness and dimensions are carefully controlled.

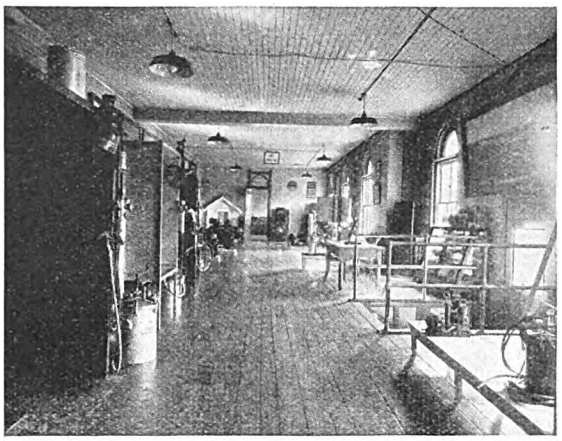
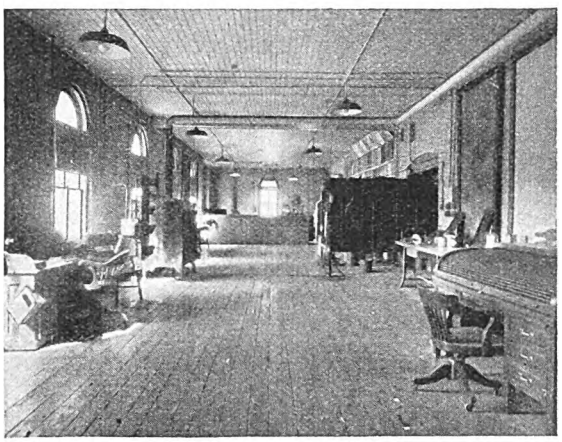
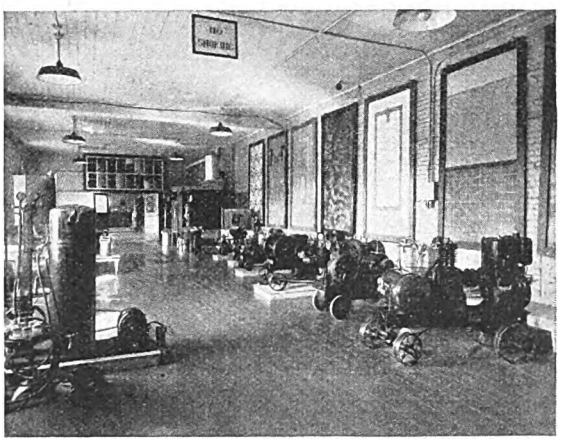
A Spray Equipment Training School





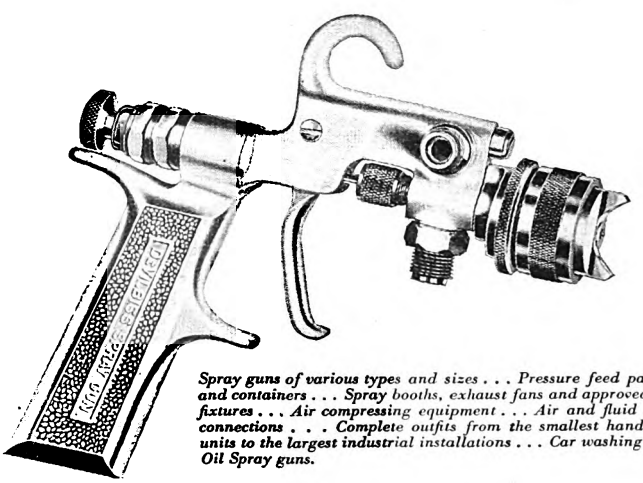


The photographs show parts of the various DeVilbiss schoolrooms in which students are trained free in the use of spray-painting and spray-finishing equipment.

Many of the most expert spray-painting and spray-finishing equipment operators were thoroughly trained free in the extensive school maintained by the DeVilbiss factory organization. Any user of DeVilbiss spray equipment may come to this school or send his men to it. There is no charge or fee. The student pays only his own living expenses.

Industrial finishing, interior decorating, house painting, the use of specialized equipment made for a particular task, the proper use of all the many materials which are applied with a spray gun—in fact every phase and detail of spray-painting and spray-finishing operations are completely and thoroughly taught. When he leaves the school, the student is a practical and skilled operator, trained to do the work he will undertake on his own job, or organize, direct and teach others.

Many of the largest electric railways have found that it pays to have their operators trained in the DeVilbiss school.



***Spray guns of various types** and sizes . . . Pressure feed paint tanks **and containers** . . . **Spray** booths, exhaust fans and approved lighting **fixtures** . . . **Air compressing** equipment . . . Air and fluid hose and **connections** . . . **Complete** outfits from the smallest hand-operated **units to the largest industrial** installations . . . Car washing guns . . . Oil Spray guns.*

ALCOA

STRONG TO BEAR BURDENS — LIGHT TO MOVE

$E = \frac{MV^2}{2}$

10,000 Pounds of Alcoa Aluminum used 13,500 Pounds of Dead-Weight Saved

This car is over six tons lighter, because the light, strong Alloys of Alcoa Aluminum were used for the body and under-frame. It was built by the Cummings Car and Coach Company, for Chicago and Joliet Electric Railway Company.

Cars that are not handicapped by excessive dead-weight can make faster runs—collect more fares every day. Even with smaller, less expensive motors, using less power, cars built of the light, strong Alloys of Alcoa Aluminum are making speedier starts, quicker stops and much faster round trips. Every run they make costs less money, not only because there are thousands of pounds less to move, but also because there are thousands of pounds less weight pounding on tracks and road bed.

The car shown here has been in service since 1927. Many other cars of aluminum have been in service longer than that. They prove that Alcoa Aluminum has all the required strength, has great resistance to corrosion, and is more profitable to operate. They are both cheaper to maintain and they attract more fares.

The light, strong Alloys of Alcoa Aluminum are easily fabricated in any standard shape. They require technique and equipment very similar to that needed for working steel.

Our nearest office will gladly send a representative to talk with you about the use of Alcoa Aluminum and its light, strong Alloys for car construction. Address ALUMINUM COMPANY *of* AMERICA; 2463 Oliver Building, PITTSBURGH, PENNSYLVANIA.

Over 2 years service under 8,000,000 heavy wheels

Measuring the amount of wear on the Bethlehem Silico - Manganese Crossing at 12th and Market Streets, Philadelphia, Pa.

BETHLEHEM Silico-Manganese Crossings Design 999 are especially suitable for heavy traffic locations. The crossing installed at 12th and Market Streets, Philadelphia, Pa., has given more than 2 years of trouble-free service under the mass traffic conditions at this busy intersection. Not withstanding this heavy service it has not been necessary to repair this crossing or build it up by welding.

Bethlehem Silico-Manganese Crossings have the hardness and toughness to resist wear. The Silico-Manganese Castings are Thermit-welded to the rails, making a solid, one-piece construction and eliminating the use of cast iron or bolts. These castings are heat treated to harden them and increase their wearing qualities. It is this heat treatment that gives to Bethlehem Silico-Manganese Crossings their remarkable resistance to initial pounding and wear. They withstand great abuse and yet are easily repaired by welding.

Editors on WHEELS
—are making your business paper!

He's out—but he's not at the country club. His chair is empty this afternoon—but it won't be tonight. He'll be back from the front with important news for you and your business.

For today your business paper is edited on wheels.

Is there a hint of a new process, a new method, a new machine that may cut costs for a whole industry? Your editor is there by the shortest, swiftest route.

Is there a rumor of impending price changes—of a merger that may affect competition—a tariff that may affect exports? Your editor is on the ground, looking at emergencies through your eyes, getting the facts for you.

Is there news of a selling plan, a packaging idea, a distribution scheme that moves goods quickly? He is there, to appraise its value to you, to bring you the story of just what happened.

No wonder your editor is not at his desk. He is riding the rails, flying the airlines, touring the roads—a reporter at the front, an editor on the way home. And he is doing it all for you. His reports, digested for you, written for you, published for you—are yours in the pages of your business paper.

THIS SYMBOL *identifies an ABP paper . . . It stands for honest, known, paid circulation; straightforward business methods, and editorial standards that insure reader interest . . . These are the factors that make a valuable advertising medium.*

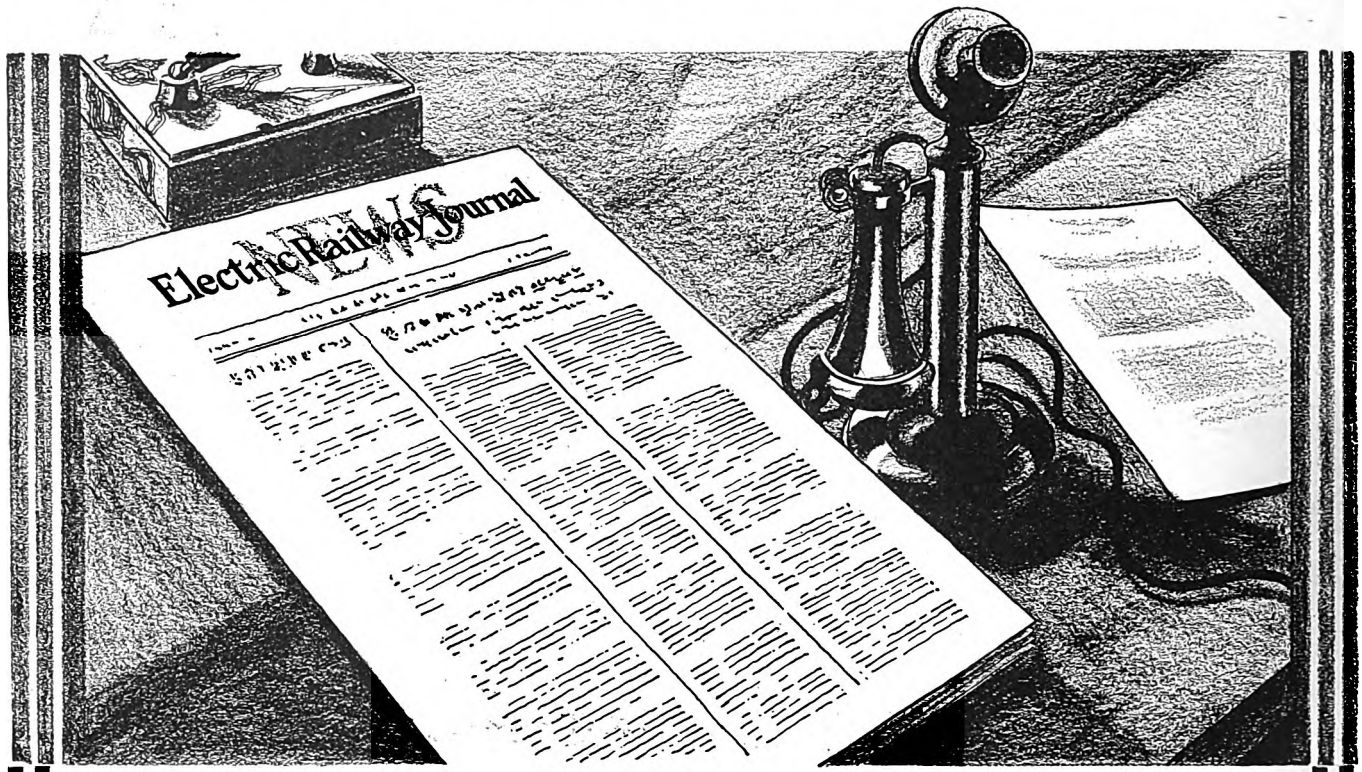
Are you receiving *The Electric Railway Journal* NEWS?



—the Newspaper of the Electric Railway Field

When *Electric Railway Journal* was changed from a weekly to a monthly magazine, electric railway men everywhere asked us to continue to supply the current news of the field.

For that reason, a supplementary service was started, known as the *Electric Railway Journal* NEWS. It appears as a separate newspaper on thirty-nine Saturdays during the year. On the other thirteen Saturdays, the magazine itself appears with current news.

The *Electric Railway Journal* NEWS keeps its readers posted on court decisions . . recent bus developments . . current legislation enacted concerning electric railways . . changes in fare rates . . news of purchasing activities . . financial and corporate notes . . editorial interpretation of vital news . . personal items on men in the field. This newspaper constitutes the most complete guide to new developments in the field.

Subscription price is low—only $2 for the complete year's service of thirty-nine issues. Foreign rate, $4 annually. Sold in combination with the monthly edition of *Electric Railway Journal* for $5 a year, domestic rate. Send no money now—simply fill in and mail the coupon today!

A whole year's driving in less than a week!

FOR five and a half days and nights, through rain, through blistering heat, three Socony test cars—standard 1931 model sedans—raced around the torturing Indianapolis Speedway, testing the *new* Socony Motor Oil.

In less than a week, at close to a mile-a-minute pace, they covered 7,290 miles—a whole year's driving . . . the equivalent of driving uphill, throttle wide open, all the way! The test was made under the strict supervision of the American Automobile Association. The results surpassed the expectations of Socony engineers after two and a half years' work!

They already *knew* it was a great *Cold Weather Oil.* Tested at 6 below zero in an airplane flying over four and three-quarters miles high, this 100% Paraffine Base dewaxed oil flowed freely. But the Indianapolis test proved something more. It proved this *new* oil does not decompose regardless of engine heat. It proved that this *new* oil maintains the proper body at abnormally high engine temperatures, giving perfect piston seal, maximum power, and minimum fuel and oil consumption; and that the new refining process reduces to a minimum all harmful elements which cause carbon, gum and sludge.

Bus owners, too, will find that the *new* Socony Motor Oil is even better in buses than Socony "Aircraft"—in fact, the ideal lubricant. We urge you to try it today.

DAYTON TIES
and the
Human Equation

Complexity of installation methods is a strong point of objection to any product for any purpose.

In track work, particularly, good results depend upon the care and thoroughness of the actual work of the laborers.

Well planned methods often go wrong from laborers' carelessness.

A method which is proof against such mistakes is most desirable.

After twelve years of use and hundreds of installations of Dayton Ties, made by every known class of track laborers, the record shows not one case where the track foundation has failed or where the ties have become loose in their bed.

The simplicity and effectiveness of the Dayton method offsets the ever present human equation.

and they cost less.

IT ISN'T ALL FUN FOR A TROLLEY WHEEL

IT'S easy for any trolley wheel to run smoothly and provide ample conductivity in balmy weather.

But when rain, snow, and sleet whip trolley wires, it isn't fun for trolley wheels.

That's where Kalamazoo Trolley Wheels prove their value. Ample conductivity is always present for those who standardize on Kalamazoo Trolley Wheels.

It is significant that many Electric Railway Companies use them as a basis for comparison.

Write for details and bulletins.

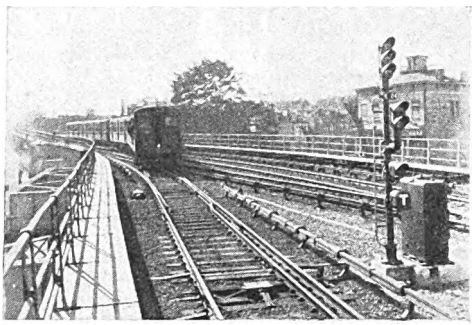
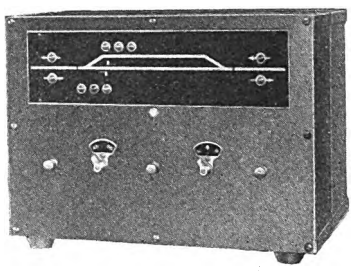
KALAMAZOO

Centralize Traffic Control





THE control of all traffic over a busy line, whether the line is a mile long or thirty or forty, can be centralized into the hands of one operator. All information necessary for the manipulation of the levers is brought to him in the most accurate manner.

Centralized Traffic Control is adaptable to a complex urban traffic system or to a long interurban line. It carries a maximum number of controls and indications over a minimum number of line wires. Such control is proving to be a great time saver and economy producer on more than 80 installations.

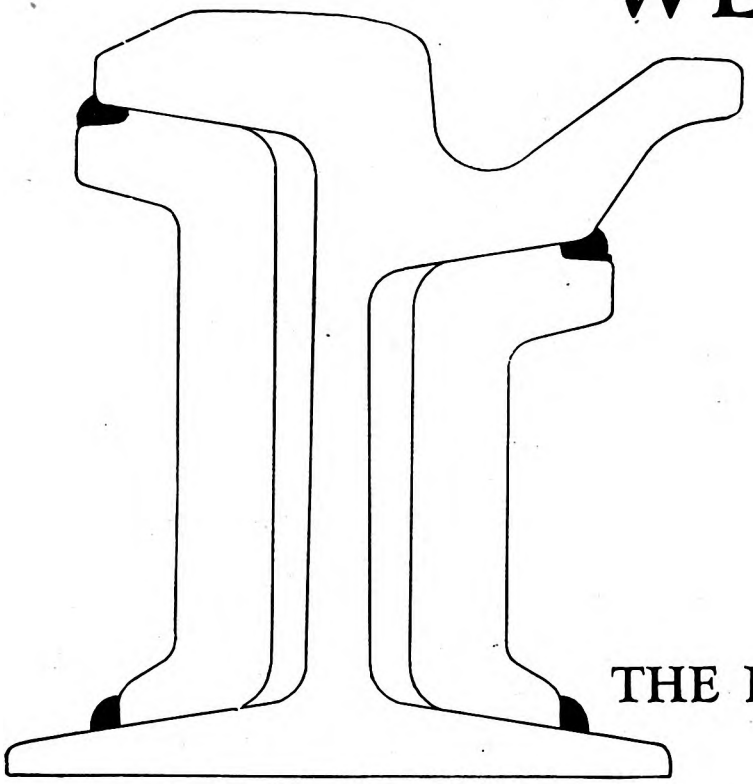
"WELD PLATES"



For EFFICIENT, ECONOMICAL

JOINTS

Do you believe in statistics? Rely on performance records? If so, the performance records of the many "Weld Plates" now in use will convince you that they lead the bar-weld joints in efficiency and economy.

"Weld Plates" represent the most modern welding practice. They are the strongest and most up-to-date plates rolled especially for electric welded joints. Note the shape—the grooves for retaining plenty of weld metal along the upper edges—the wide contact areas at top and bottom—the suitability for the use of short bolts.

A trial will convince you of their efficiency and economy.

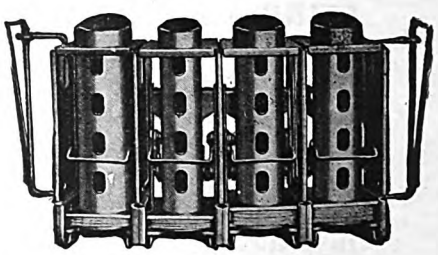
John A. Roebling's Sons Company, Trenton, N. J., Makers of Wire Rope and Wire

JOHNSON FARE COLLECTING SYSTEMS

Johnson Electric Fare Boxes and overhead registers make possible the instantaneous registering and counting of every fare. Revenues are increased 1½ to 5% and the efficiency of one-man operation is materially increased. Quicker boarding of passengers with resultant reduction in running time for the buses. Over 5000 already in use.

When more than three coins are used as fare, the Type D Johnson Fare Box is the best manually operated registration system. Over 50,000 in use.

Johnson Change-Makers are designed to function with odd fare and metal tickets selling at fractional rates. It is possible to use each barrel separately or in groups to meet local conditions. Each barrel can be adjusted to eject from one to five coins or one to six tokens.



Johnson Fare Box Co.

4619 Ravenswood Ave., Chicago, Ill.

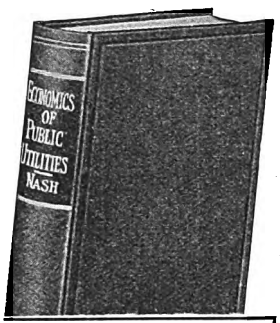
Your name stamped FREE on this book

At no additional cost, we will stamp your name or the name of a friend in gold on the front cover of every copy of Nash's **Economics of Public Utilities** ordered from this advertisement. This is a special Christmas offer, limited to acceptance before January 1, 1931.

a comprehensive treatment of the business and economic problems of public utilities



This book presents the essential facts and the most mature view upon the underlying financial and economic phases of public utility companies, with particular emphasis on electric railways, electric light and power companies and gas companies.

Economics of Public Utilities

By L. R. NASH
Public Utility Engineer, Stone and Webster, Inc.
413 pages, 6x9, $4.00

This book discusses every angle of the public utility as a business and treats thoroughly such subjects as capitalization, investment features, franchises, regulation, valuation, depreciation, taxes, rates, service, accounting methods, public relations, etc.

Mr. Nash has drawn from his experience of more than twenty-five years in the business of designing, constructing and managing public utility properties for the data on which this book is based. The comprehensive view it offers of the business and economic phases of public utility enterprises will be of value to utility officials, bankers, investors, engineers, lawyers, accountants, public officials and the economist and business man.

CONTENTS:
1.—Origin and Development of Public Utilities. 2.—Distinguishing Characteristics of Public Utilities. 3.—Franchises. 4.—Capitalization. 5.—Accounting Methods. 6.—Regulation. 7.—Valuation. 8.—Depreciation. 9.—Rate of Return to Investors. 10.—Rate Structures. 11.—Taxation. 12.—Tests of Utility Securities as Investments. 13.—Tests of Utility Development. 14.—Public Ownership. 15.—Public Relations. 16.—Some Current Utility Problems. 17.—Views on Outstanding Issues.

Do you want to make a friend a gift that combines personal thoughtfulness with real utility? Do you want a copy of Nash that you will doubly prize? Then take advantage of this free stamping offer. Send the coupon today. Remittance should be enclosed with order, and, of course, stamped books are not returnable.

SPECIAL HOLIDAY OFFER COUPON

McGraw-Hill Book Co., Inc., 370 Seventh Ave., New York City:

Send me Nash—Economics of Public Utilities, with name below stamped in gold. I enclose $4.00 and understand that stamped books are not returnable. (This offer expires Jan. 1, 1931.)

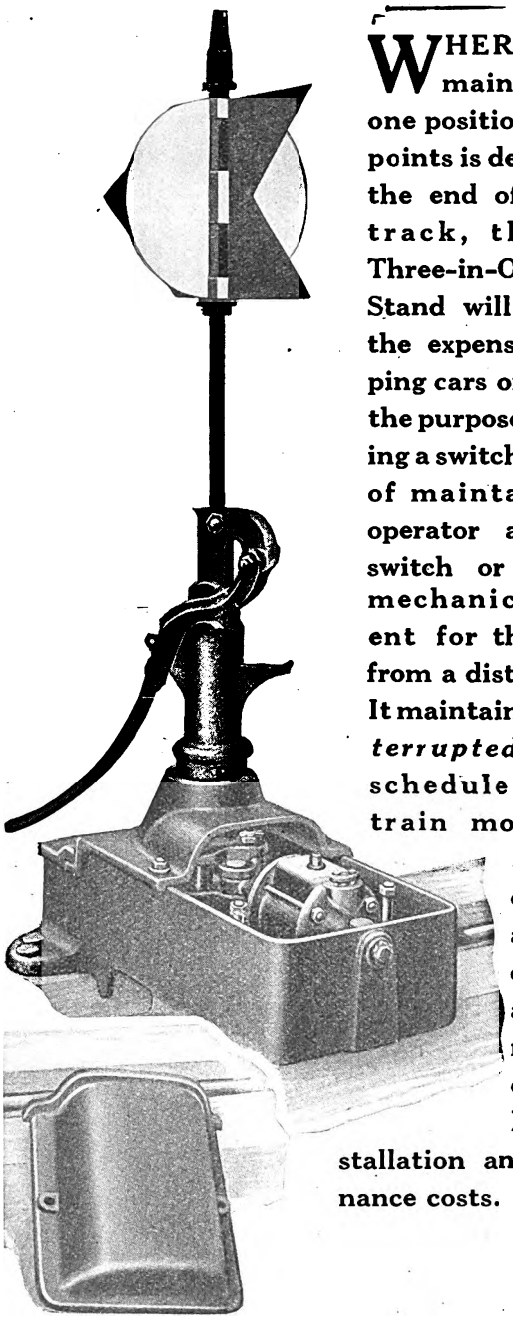
FOR THE ACCOMPLISHMENT OF ECONOMY WITH SAFETY . . . . .

The New Racor Three-in-One Switch Stand



WHEREVER the maintenance of one position of switch points is desired, as at the end of a double track, the Racor Three-in-One Switch Stand will eliminate the expense of stopping cars or trains for the purpose of throwing a switch or the cost of maintaining an operator at such a switch or expensive mechanical equipment for throwing it from a distant tower. It maintains an *uninterrupted* routine schedule of car or train movements; safeguards equipment at these locations and promotes economies in lowered installation and maintenance costs.

Behind Racor Service stand nine plants specializing in the manufacture and distribution of railroad track turnout and crossing equipment, including Manganese Work for heavy traffic.

OKOCORD

MAKES IDEAL MOTOR LEADS

TOUGH, KINK-PROOF, WATERPROOF oil, acid, alkali resistant and very flexible...these properties make OKOCORD ideal for motor leads.

For this purpose, OKOCORD is made with extra flexible conductors, each wire being carefully tinned. The whole conductor is then wrapped with a paper separator to keep the rubber away from it, which facilitates skinning and soldering. The tough, tread-rubber sheath insulates and protects the conductor from all external damage.

If you haven't used it for this purpose, send for a trial order and learn for yourself how economical it is.

Right on top of this maintenance problem

DIXON'S Bright Aluminum Paint

. . . for car roofs

Electric railway operators using DIXON'S Bright Aluminum Paint have been able to cut down one big item of excessive maintenance. And they have transferred a maintenance overhead to the revenue-building side of their ledgers. They are painting car roofs with Bright Aluminum.

Here is two-fold value in a single investment—the tremendous durability of the straight aluminum pigment in a tough vehicle of spar varnish which insures long service life and low cost per year of service—and the enduringly bright, non-discoloring appearance which attracts patronage.

Try it the next time your cars go in the shop for repainting. You can brush it or spray it on, easily, quickly.

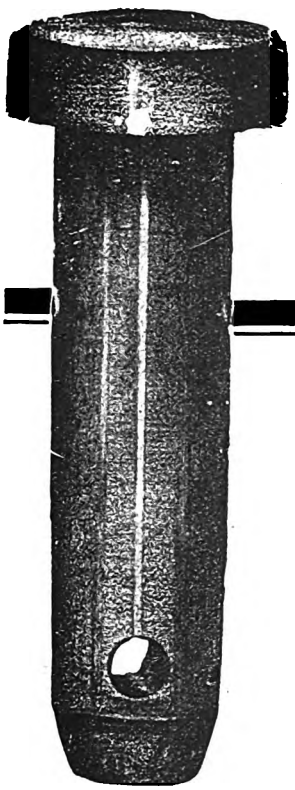
A maintenance plan is for the "long run" Boyerized Parts fit!



No make-shift materials should enter any well conceived electric railway maintenance plan. For there are two known factors which must always be faced. The extraordinary wear to which each part is subjected, and the necessity for increasing the interval between jobs.

Boyerized Parts are made by special process to fit the plan which is based on "long runs" between repair jobs. They last three or four times longer than ordinary parts. In addition they . . . 1. Reduce replacements, 2. Cut labor costs, 3. And prevent costly break-downs.

Make Boyerizing a part of your maintenance plan. Check the list and send us a trial order today.

Scheduled cleaning preserves surfaces and saves money

CLEANING cars and busses at the end of each day's run is an economical measure that helps preserve painted surfaces and maintains their attractive appearance.

A growing number of railway and bus fleet superintendents have found that the Oakite way of doing this is both economical and effective. Road dirt, grease, and spots are removed *without injury to painted wood or metal surfaces.* The emulsifying action of the Oakite solution breaks up the grime so that a cold water rinse leaves paintwork film-free and without signs of streaks. Original brilliancy is preserved, and the intervals between repainting become noticeably longer.

Full information on economical Oakite materials and methods for this and other electric railway cleaning jobs is contained in our booklet, "Oakite for Railroads." If you operate a bus fleet you will also profit from our booklet, "Oakite for Garages, Service Stations and Repair Shops." Write for your copies. No obligation.

Oakite Service Men, cleaning specialists, are located in the leading industrial centers of the U. S. and Canada

Quicker Stops ARE A Factor in Offering A Better Service

In these days of keen competition every operator is anxious to offer a fast, clean, comfortable service and one important factor in a fast service is quicker stops.

Ordinary brake shoes may have been satisfactory at one time but present day operating conditions make it necessary that the most efficient brake shoe obtainable be used.

"Diamond-S" brake shoes are the most efficient as well as the most economical to use in any service.

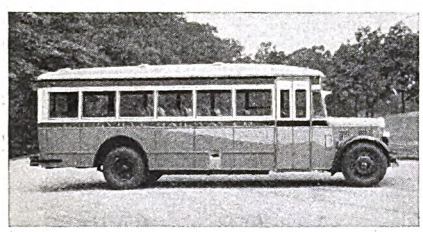
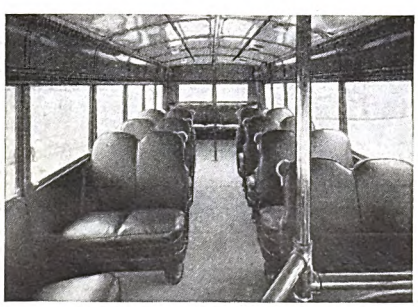
Every Day More People Travel In BENDER BODIES





UNQUESTIONABLY, riders are attracted by the graceful lines and beautiful appearance of Bender Buses . . . Exceptionally comfortable seats, good lighting, ventilation and wide aisles . . . in fact, everything possible inside for passenger comfort and safety makes them permanent riders.

What passengers cannot see, but equally important, are the factors of exceptionally sturdy construction, first quality materials carefully inspected, skillful fitting, secure jointing, rigid welding and extra reinforcement. These and many other important features are typical of Bender advanced construction, insuring safety for passengers and long-time running, giving operators better value per dollar invested.

No wonder that every day more people travel in Bender Bodies.

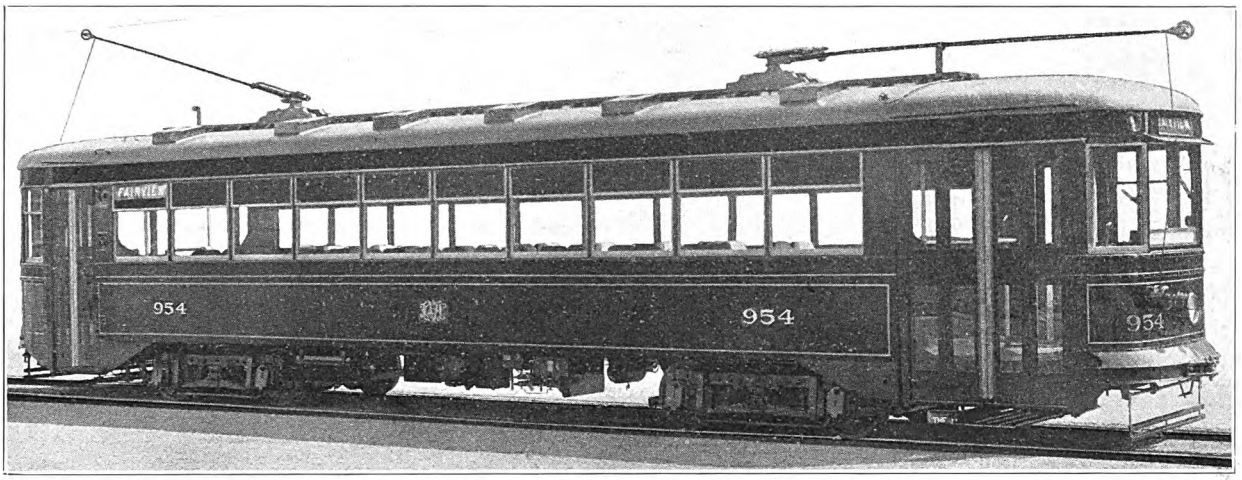
Allentown Introduces Ten New Double-end Cars



action

The number of cities recognizing that action is necessary if the modern public transportation problem is to be met is growing. As evidence we present the following recent new car installations:

New modern cars, faster schedules, with maximum comfort and convenience—the best way to meet present-day competition.

BALTIMORE	One hundred and fifty single-end front-entrance center-exit cars, mounted on Brill 177-E-1 Trucks.
SANTIAGO	Thirty double-end suburban cars on Brill 177-E-1-X Trucks.
YORK	Three double-end city cars mounted on the new Brill 84-E-1-X Trucks.
ALLENTOWN	Ten double-end cars mounted on Brill 177-E-1-X Trucks.

Recognition of the importance of new cars is one thing; placing them in service is another. Without action there can be no improvement.

A SMALL CAPACITY Mack

17 passenger Interstate—21 passenger City Service

In the new small-capacity Mack BG, operators can now obtain a light, flexible yet husky bus, *ESPECIALLY* designed for light runs in city service; on interurban routes and for school work.

For the first time Mack quality is available in a small bus, assuring long life, reliability, minimum depreciation, low maintenance, and those low costs that are so essential on thin lines.

The Mack BG assures lower costs and increased profits in the small-capacity field as surely as other Mack models always have in larger-capacity service.
